• For ‘trf’ and ‘dogbox’: norm(dx) < xtol * (xtol + norm(x))
• For ‘lm’: Delta < xtol * norm(xs), where Delta is a trust-region radius
and xs is the value of x scaled according to x_scale parameter (see below).

gtol : float, optional
Tolerance for termination by the norm of the gradient. Default is 1e-8. The exact
condition depends on a method used:
• For ‘trf’: norm(g_scaled, ord=np.inf) < gtol, where g_scaled is
the value of the gradient scaled to account for the presence of the bounds [STIR].
• For ‘dogbox’: norm(g_free, ord=np.inf) < gtol, where g_free is the
gradient with respect to the variables which are not in the optimal state on the bound-
ary.
• For ‘lm’: the maximum absolute value of the cosine of angles between columns of
the Jacobian and the residual vector is less than gtol, or the residual vector is zero.

x_scale : array_like or ‘jac’, optional
Characteristic scale of each variable. Setting x_scale is equivalent to reformulating
the problem in scaled variables xs = x / x_scale. An alternative view is that the
size of a trust region along j-th dimension is proportional to x_scale[j]. Improved
convergence may be achieved by setting x_scale such that a step of a given size along
any of the scaled variables has a similar effect on the cost function. If set to ‘jac’,
the scale is iteratively updated using the inverse norms of the columns of the Jacobian
matrix (as described in [JJMore]).

loss : str or callable, optional
Determines the loss function. The following keyword values are allowed:
• ‘linear’ (default): rho(z) = z. Gives a standard least-squares problem.
• ‘soft_l1’ : \( \rho(z) = 2 \times ((1 + z)**0.5 - 1) \). The smooth approximation of L1 (absolute value) loss. Usually a good choice for robust least squares.
• ‘huber’ : \( \rho(z) = z \) if \( z \leq 1 \) else \( 2z^{0.5} - 1 \). Works similarly to ‘soft_l1’.
• ‘cauchy’ : \( \rho(z) = \ln(1 + z) \). Severely weakens outliers influence, but may cause difficulties in optimization process.
• ‘arctan’ : \( \rho(z) = \arctan(z) \). Limits a maximum loss on a single residual, has properties similar to ‘cauchy’.

If callable, it must take a 1-d ndarray \( z = f**2 \) and return an array_like with shape (3, m) where row 0 contains function values, row 1 contains first derivatives and row 2 contains second derivatives. Method ‘lm’ supports only ‘linear’ loss.

**f_scale** : float, optional
Value of soft margin between inlier and outlier residuals, default is 1.0. The loss function is evaluated as follows \( \rho_{\text{soft}}(f**2) = C^2 \times \rho(f**2 / C^2) \), where \( C \) is \( f\text{scale} \), and \( \rho \) is determined by \( \text{loss} \) parameter. This parameter has no effect with \( \text{loss} = \text{‘linear’} \), but for other \( \text{loss} \) values it is of crucial importance.

**max_nfev** : None or int, optional
Maximum number of function evaluations before the termination. If None (default), the value is chosen automatically:
• For ‘trf’ and ‘dogbox’ : 100 * n.
• For ‘lm’ : 100 * n if jac is callable and 100 * n * (n + 1) otherwise (because ‘lm’ counts function calls in Jacobian estimation).

**diff_step** : None or array_like, optional
Determines the relative step size for the finite difference approximation of the Jacobian. The actual step is computed as \( x \times \text{diff_step} \). If None (default), then \text{diff_step} is taken to be a conventional “optimal” power of machine epsilon for the finite difference scheme used [NR].

**tr_solver** : {None, ‘exact’, ‘lsmr’}, optional
Method for solving trust-region subproblems, relevant only for ‘trf’ and ‘dogbox’ methods.
• ‘exact’ is suitable for not very large problems with dense Jacobian matrices. The computational complexity per iteration is comparable to a singular value decomposition of the Jacobian matrix.
• ‘lsmr’ is suitable for problems with sparse and large Jacobian matrices. It uses the iterative procedure \text{scipy.sparse.linalg.lsmr} for finding a solution of a linear least-squares problem and only requires matrix-vector product evaluations.

If None (default) the solver is chosen based on the type of Jacobian returned on the first iteration.

**tr_options** : dict, optional
Keyword options passed to trust-region solver.
• tr_solver=’exact’: \text{tr_options} are ignored.
• tr_solver=’lsmr’: options for \text{scipy.sparse.linalg.lsmr}. Additionally method=’trf’ supports ‘regularize’ option (bool, default is True) which adds a regularization term to the normal equation, which improves convergence if the Jacobian is rank-deficient [Byrd] (eq. 3.4).

**jac_sparsity** : {None, array_like, sparse matrix}, optional
Defines the sparsity structure of the Jacobian matrix for finite difference estimation, its shape must be (m, n). If the Jacobian has only few non-zero elements in each row, providing the sparsity structure will greatly speed up the computations [Curtis]. A zero entry means that a corresponding element in the Jacobian is identically zero. If provided, forces the use of ‘lsmr’ trust-region solver. If None (default) then dense differencing will be used. Has no effect for ‘lm’ method.

**verbose** : {0, 1, 2}, optional
Level of algorithm’s verbosity:
0 (default) : work silently.
1 : display a termination report.
2 : display progress during iterations (not supported by ‘lm’ method).

args, kwargs : tuple and dict, optional
Additional arguments passed to fun and jac. Both empty by default. The calling signature is fun(x, *args, **kwargs) and the same for jac.

Returns

OptimizeResult with the following fields defined:
x : ndarray, shape (n,)
Solution found.
cost : float
Value of the cost function at the solution.
fun : ndarray, shape (m,)
Vector of residuals at the solution.
jac : ndarray, sparse matrix or LinearOperator, shape (m, n)
Modified Jacobian matrix at the solution, in the sense that J^T J is a Gauss-Newton approximation of the Hessian of the cost function. The type is the same as the one used by the algorithm.
grad : ndarray, shape (m,)
Gradient of the cost function at the solution.
optimality : float
First-order optimality measure. In unconstrained problems, it is always the uniform norm of the gradient. In constrained problems, it is the quantity which was compared with gtol during iterations.
active_mask : ndarray of int, shape (n,)
Each component shows whether a corresponding constraint is active (that is, whether a variable is at the bound):
0 : a constraint is not active.
-1 : a lower bound is active.
1 : an upper bound is active.
Might be somewhat arbitrary for ‘trf’ method as it generates a sequence of strictly feasible iterates and active_mask is determined within a tolerance threshold.
nfev : int
Number of function evaluations done. Methods ‘trf’ and ‘dogbox’ do not count function calls for numerical Jacobian approximation, as opposed to ‘lm’ method.
njev : int or None
Number of Jacobian evaluations done. If numerical Jacobian approximation is used in ‘lm’ method, it is set to None.
status : int
The reason for algorithm termination:
-1 : improper input parameters status returned from MINPACK.
0 : the maximum number of function evaluations is exceeded.
1 : gtol termination condition is satisfied.
2 : ftol termination condition is satisfied.
3 : xtol termination condition is satisfied.
4 : Both ftol and xtol termination conditions are satisfied.
message : str
Verbal description of the termination reason.
success : bool
True if one of the convergence criteria is satisfied (status > 0).

leastsq A legacy wrapper for the MINPACK implementation of the Levenberg-Marquadt algorithm.
curve_fit Least-squares minimization applied to a curve fitting problem.
Notes

Method ‘lm’ (Levenberg-Marquardt) calls a wrapper over least-squares algorithms implemented in MINPACK (lmder, lmdif). It runs the Levenberg-Marquardt algorithm formulated as a trust-region type algorithm. The implementation is based on paper [JJMore], it is very robust and efficient with a lot of smart tricks. It should be your first choice for unconstrained problems. Note that it doesn’t support bounds. Also it doesn’t work when m < n.

Method ‘trf’ (Trust Region Reflective) is motivated by the process of solving a system of equations, which constitute the first-order optimality condition for a bound-constrained minimization problem as formulated in [STIR]. The algorithm iteratively solves trust-region subproblems augmented by a special diagonal quadratic term and with trust-region shape determined by the distance from the bounds and the direction of the gradient. This enhancements help to avoid making steps directly into bounds and efficiently explore the whole space of variables. To further improve convergence, the algorithm considers search directions reflected from the bounds. To obey theoretical requirements, the algorithm keeps iterates strictly feasible. With dense Jacobians trust-region subproblems are solved by an exact method very similar to the one described in [JJMore] (and implemented in MINPACK). The difference from the MINPACK implementation is that a singular value decomposition of a Jacobian matrix is done once per iteration, instead of a QR decomposition and series of Givens rotation eliminations. For large sparse Jacobians a 2-d subspace approach of solving trust-region subproblems is used [STIR], [Byrd]. The subspace is spanned by a scaled gradient and an approximate Gauss-Newton solution delivered by scipy.sparse.linalg.lsmr. When no constraints are imposed the algorithm is very similar to MINPACK and has generally comparable performance. The algorithm works quite robust in unbounded and bounded problems, thus it is chosen as a default algorithm.

Method ‘dogbox’ operates in a trust-region framework, but considers rectangular trust regions as opposed to conventional ellipsoids [Voglis]. The intersection of a current trust region and initial bounds is again rectangular, so on each iteration a quadratic minimization problem subject to bound constraints is solved approximately by Powell’s dogleg method [NumOpt]. The required Gauss-Newton step can be computed exactly for dense Jacobians or approximately by scipy.sparse.linalg.lsmr for large sparse Jacobians. The algorithm is likely to exhibit slow convergence when the rank of Jacobian is less than the number of variables. The algorithm often outperforms ‘trf’ in bounded problems with a small number of variables.

Robust loss functions are implemented as described in [BA]. The idea is to modify a residual vector and a Jacobian matrix on each iteration such that computed gradient and Gauss-Newton Hessian approximation match the true gradient and Hessian approximation of the cost function. Then the algorithm proceeds in a normal way, i.e. robust loss functions are implemented as a simple wrapper over standard least-squares algorithms.

New in version 0.17.0.

Examples

In this example we find a minimum of the Rosenbrock function without bounds on independent variables.

```python
>>> def fun_rosenbrock(x):
...     return np.array([10 * (x[1] - x[0]**2), (1 - x[0])])

array([ 1., 1.])
```

Notice that we only provide the vector of the residuals. The algorithm constructs the cost function as a sum of squares of the residuals, which gives the Rosenbrock function. The exact minimum is at $x = [1.0, 1.0]$.

```python
>>> from scipy.optimize import least_squares
>>> x0_rosenbrook = np.array([2, 2])
>>> res_1 = least_squares(fun_rosenbrook, x0_rosenbrook)
>>> res_1.x
array([1., 1.])
```
We now constrain the variables, in such a way that the previous solution becomes infeasible. Specifically, we require that \( x[1] \geq 1.5 \), and \( x[0] \) left unconstrained. To this end, we specify the \textit{bounds} parameter to \texttt{least_squares} in the form \texttt{bounds=([-np.inf, 1.5], np.inf)}.

We also provide the analytic Jacobian:

```
>>> def jac_rosenbrock(x):
...     return np.array([[-20 * x[0], 10], [-1, 0]])
```

Putting this all together, we see that the new solution lies on the bound:

```
>>> res_2 = least_squares(fun_rosenbrock, x0_rosenbrock, jac_rosenbrock,
...                       bounds=([-np.inf, 1.5], np.inf))
>>> res_2.x
array([ 1.22437075, 1.5])
>>> res_2.cost
0.025213093946805685
>>> res_2.optimality
1.5885401433157753e-07
```

Now we solve a system of equations (i.e., the cost function should be zero at a minimum) for a Broyden tridiagonal vector-valued function of 100000 variables:

```
>>> def fun_broyden(x):
...     f = (3 - x) * x + 1
...     f[:-1] -= x[:-1]
...     f[-1] -= 2 * x[1:] # boundary condition
...     return f
```

The corresponding Jacobian matrix is sparse. We tell the algorithm to estimate it by finite differences and provide the sparsity structure of Jacobian to significantly speed up this process.

```
>>> from scipy.sparse import lil_matrix
>>> def sparsity_broyden(n):
...     sparsity = lil_matrix((n, n), dtype=int)
...     i = np.arange(n)
...     sparsity[i, i] = 1
...     i = np.arange(1, n)
...     sparsity[i, i - 1] = 1
...     i = np.arange(n - 1)
...     sparsity[i, i + 1] = 1
...     return sparsity
```

```
>>> n = 100000
>>> x0_broyden = -np.ones(n)
... >>>
>>> res_3 = least_squares(fun_broyden, x0_broyden,
...                        jac_sparsity=sparsity_broyden(n))
>>> res_3.cost
4.5687069299604613e-23
```
Let’s also solve a curve fitting problem using robust loss function to take care of outliers in the data. Define the model function as $y = a + b \times \exp(c \times t)$, where $t$ is a predictor variable, $y$ is an observation and $a$, $b$, $c$ are parameters to estimate.

First, define the function which generates the data with noise and outliers, define the model parameters, and generate data:

```python
>>> def gen_data(t, a, b, c, noise=0, n_outliers=0, random_state=0):
...     y = a + b * np.exp(t * c)
...     rnd = np.random.RandomState(random_state)
...     error = noise * rnd.randn(t.size)
...     outliers = rnd.randint(0, t.size, n_outliers)
...     error[outliers] *= 10
...     return y + error
...
>>> a = 0.5
>>> b = 2.0
>>> c = -1
>>> t_min = 0
>>> t_max = 10
>>> n_points = 15
>>> t_train = np.linspace(t_min, t_max, n_points)
>>> y_train = gen_data(t_train, a, b, c, noise=0.1, n_outliers=3)
```

Define function for computing residuals and initial estimate of parameters.

```python
>>> def fun(x, t, y):
...     return x[0] + x[1] * np.exp(x[2] * t) - y
...
>>> x0 = np.array([1.0, 1.0, 0.0])
```

Compute a standard least-squares solution:

```python
>>> res_lsq = least_squares(fun, x0, args=(t_train, y_train))
```

Now compute two solutions with two different robust loss functions. The parameter $f$ _scale_ is set to 0.1, meaning that inlier residuals should not significantly exceed 0.1 (the noise level used).

```python
>>> res_soft_l1 = least_squares(fun, x0, loss='soft_l1', f_scale=0.1,
...                              args=(t_train, y_train))
>>> res_log = least_squares(fun, x0, loss='cauchy', f_scale=0.1,
...                          args=(t_train, y_train))
```

And finally plot all the curves. We see that by selecting an appropriate loss we can get estimates close to optimal even in the presence of strong outliers. But keep in mind that generally it is recommended to try ‘soft_l1’ or ‘huber’ losses first (if at all necessary) as the other two options may cause difficulties in optimization process.

```python
>>> t_test = np.linspace(t_min, t_max, n_points * 10)
>>> y_true = gen_data(t_test, a, b, c)
>>> y_lsq = gen_data(t_test, *res_lsq.x)
>>> y_soft_l1 = gen_data(t_test, *res_soft_l1.x)
>>> y_log = gen_data(t_test, *res_log.x)
```
In the next example, we show how complex-valued residual functions of complex variables can be optimized with `least_squares()`. Consider the following function:

```python
>>> def f(z):
...     return z - (0.5 + 0.5j)
```

We wrap it into a function of real variables that returns real residuals by simply handling the real and imaginary parts as independent variables:

```python
>>> def f_wrap(x):
...     fx = f(x[0] + 1j*x[1])
...     return np.array([fx.real, fx.imag])
```

Thus, instead of the original m-dimensional complex function of n complex variables we optimize a 2m-dimensional real function of 2n real variables:

```python
>>> from scipy.optimize import least_squares
>>> res_wrapped = least_squares(f_wrap, (0.1, 0.1), bounds=(0, 0), (1, 1))
>>> z = res_wrapped.x[0] + res_wrapped.x[1]*1j
>>> z
(0.4999999999999999, 0.4999999999999999)
```

The `scipy.optimize.nnls(A, b)` function solves $\text{argmin}_x \| Ax - b \|_2$ for $x \geq 0$. This is a wrapper for a FORTRAN non-negative least squares solver.
Parameters

A : ndarray
   Matrix A as shown above.

b : ndarray
   Right-hand side vector.

Returns

x : ndarray
   Solution vector.

rnorm : float
   The residual, || A x - b ||_2.

Notes

The FORTRAN code was published in the book below. The algorithm is an active set method. It solves the KKT (Karush-Kuhn-Tucker) conditions for the non-negative least squares problem.

References

scipy.optimize.lsq_linear(A, b, bounds=(-inf, inf), method='trf', tol=1e-10, lsq_solver=None, lsmr_tol=None, max_iter=None, verbose=0)

Solve a linear least-squares problem with bounds on the variables.

Given a m-by-n design matrix A and a target vector b with m elements, lsq_linear solves the following optimization problem:

\[
\begin{align*}
\text{minimize} & \quad 0.5 * ||A x - b||^2 \\
\text{subject to} & \quad l_b <= x <= u_b
\end{align*}
\]

This optimization problem is convex, hence a found minimum (if iterations have converged) is guaranteed to be global.

Parameters

A : array_like, sparse matrix of LinearOperator, shape (m, n)

b : array_like, shape (m,)
   Target vector.

bounds : 2-tuple of array_like, optional
   Lower and upper bounds on independent variables. Defaults to no bounds. Each array must have shape (n,) or be a scalar, in the latter case a bound will be the same for all variables. Use np.inf with an appropriate sign to disable bounds on all or some variables.

method : 'trf' or 'bvls', optional
   Method to perform minimization.
   • 'trf' : Trust Region Reflective algorithm adapted for a linear least-squares problem. This is an interior-point-like method and the required number of iterations is weakly correlated with the number of variables.
   • 'bvls' : Bounded-Variable Least-Squares algorithm. This is an active set method, which requires the number of iterations comparable to the number of variables. Can’t be used when A is sparse or LinearOperator.

Default is 'trf'.

tol : float, optional
   Tolerance parameter. The algorithm terminates if a relative change of the cost function is less than tol on the last iteration. Additionally the first-order optimality measure is considered:
   • method='trf' terminates if the uniform norm of the gradient, scaled to account for the presence of the bounds, is less than tol.
   • method='bvls' terminates if Karush-Kuhn-Tucker conditions are satisfied within tol tolerance.
lsq_solver : {None, ‘exact’, ‘lsmr’}, optional
    Method of solving unbounded least-squares problems throughout iterations:
    • ‘exact’ : Use dense QR or SVD decomposition approach. Can’t be used when \( A \) is
      sparse or LinearOperator.
    • ‘lsmr’ : Use \texttt{scipy.sparse.linalg.lsmr} iterative procedure which requires
      only matrix-vector product evaluations. Can’t be used with \texttt{method='bvls'}.
    If None (default) the solver is chosen based on type of \( A \).

lsmr_tol : None, float or ‘auto’, optional
    Tolerance parameters ‘atol’ and ‘btol’ for \texttt{scipy.sparse.linalg.lsmr} If None
    (default), it is set to \( 1e-2 \times \text{tol} \). If ‘auto’, the tolerance will be adjusted based on
    the optimality of the current iterate, which can speed up the optimization process, but
    is not always reliable.

max_iter : None or int, optional
    Maximum number of iterations before termination. If None (default), it is set to 100 for
    \texttt{method='trf'} or to the number of variables for \texttt{method='bvls'} (not counting
    iterations for ‘bvls’ initialization).

verbose : {0, 1, 2}, optional
    Level of algorithm’s verbosity:
    • 0 : work silently (default).
    • 1 : display a termination report.
    • 2 : display progress during iterations.

Returns
    \texttt{OptimizeResult} with the following fields defined:

x : ndarray, shape (n,)
    Solution found.

cost : float
    Value of the cost function at the solution.

fun : ndarray, shape (m,)
    Vector of residuals at the solution.

optimality : float
    First-order optimality measure. The exact meaning depends on \texttt{method}, refer to the
    description of \texttt{tol} parameter.

active_mask : ndarray of int, shape (n,)
    Each component shows whether a corresponding constraint is active (that is, whether a
    variable is at the bound):
    • 0 : a constraint is not active.
    • 1 : a lower bound is active.
    • 1 : an upper bound is active.
    Might be somewhat arbitrary for the \texttt{trf} method as it generates a sequence of strictly
    feasible iterates and active_mask is determined within a tolerance threshold.

nit : int
    Number of iterations. Zero if the unconstrained solution is optimal.

status : int
    Reason for algorithm termination:
    • -1 : the algorithm was not able to make progress on the last iteration.
    • 0 : the maximum number of iterations is exceeded.
    • 1 : the first-order optimality measure is less than \texttt{tol}.
    • 2 : the relative change of the cost function is less than \texttt{tol}.
    • 3 : the unconstrained solution is optimal.

message : str
    Verbal description of the termination reason.

success : bool
    True if one of the convergence criteria is satisfied (\texttt{status} > 0).

See also:
nnls

Linear least squares with non-negativity constraint.

least_squares

Nonlinear least squares with bounds on the variables.

Notes

The algorithm first computes the unconstrained least-squares solution by `numpy.linalg.lstsq` or `scipy.sparse.linalg.lsmr` depending on `lsq_solver`. This solution is returned as optimal if it lies within the bounds.

Method ‘trf’ runs the adaptation of the algorithm described in [STIR] for a linear least-squares problem. The iterations are essentially the same as in the nonlinear least-squares algorithm, but as the quadratic function model is always accurate, we don’t need to track or modify the radius of a trust region. The line search (backtracking) is used as a safety net when a selected step does not decrease the cost function. Read more detailed description of the algorithm in `scipy.optimize.least_squares`.

Method ‘bvls’ runs a Python implementation of the algorithm described in [BVLS]. The algorithm maintains active and free sets of variables, on each iteration chooses a new variable to move from the active set to the free set and then solves the unconstrained least-squares problem on free variables. This algorithm is guaranteed to give an accurate solution eventually, but may require up to n iterations for a problem with n variables. Additionally, an ad-hoc initialization procedure is implemented, that determines which variables to set free or active initially. It takes some number of iterations before actual BVLS starts, but can significantly reduce the number of further iterations.

References

[STIR], [BVLS]

Examples

In this example a problem with a large sparse matrix and bounds on the variables is solved.

```python
>>> from scipy.sparse import rand
>>> from scipy.optimize import lsq_linear
... >>> np.random.seed(0)
... >>> m = 20000
>>> n = 10000
... >>> A = rand(m, n, density=1e-4)
>>> b = np.random.randn(m)
... >>> lb = np.random.randn(n)
>>> ub = lb + 1
... >>> res = lsq_linear(A, b, bounds=(lb, ub), lsmr_tol='auto', verbose=1)
# may vary
The relative change of the cost function is less than `tol`. Number of iterations 16, initial cost 1.5039e+04, final cost 1.1112e+04, first-order optimality 4.66e-08.

**Scipy.optimize.basinhopping**

Find the global minimum of a function using the basin-hopping algorithm.

**Parameters**

- `func`: callable `f(x, *args)`
  - Function to be optimized. `args` can be passed as an optional item in the dict `minimizer_kwargs`.
- `x0`: `ndarray`
  - Initial guess.
- `niter`: integer, optional
  - The number of basin hopping iterations.
- `T`: float, optional
  - The “temperature” parameter for the accept or reject criterion. Higher “temperatures” mean that larger jumps in function value will be accepted. For best results `T` should be comparable to the separation (in function value) between local minima.
- `stepsize`: float, optional
  - Initial step size for use in the random displacement.
- `minimizer_kwargs`: dict, optional
  - Extra keyword arguments to be passed to the minimizer `scipy.optimize.minimize()`. Some important options could be:
    - `method` [str] The minimization method (e.g. "L-BFGS-B")
    - `args` [tuple] Extra arguments passed to the objective function (`func`) and its derivatives (Jacobian, Hessian).
- `take_step`: callable `take_step(x)`, optional
  - Replace the default step taking routine with this routine. The default step taking routine is a random displacement of the coordinates, but other step taking algorithms may be better for some systems. `take_step` can optionally have the attribute `take_step`.
- `stepsize`: float, optional
  - `stepsize` in order to try to optimize the global minimum search.
- `accept_test`: callable, `accept_test(f_new=f_new, x_new=x_new, f_old=f_old, x_old=x_old)`, optional
  - Define a test which will be used to judge whether or not to accept the step. This will be used in addition to the Metropolis test based on “temperature” `T`. The acceptable return values are True, False, or "force accept". If any of the tests return False then the step is rejected. If the latter, then this will override any other tests in order to accept the step. This can be used, for example, to forcefully escape from a local minimum that `basinhopping` is trapped in.
- `callback`: callable, `callback(x, f, accept)`, optional
  - A callback function which will be called for all minima found. `x` and `f` are the coordinates and function value of the trial minimum, and `accept` is whether or not that minimum was accepted. This can be used, for example, to save the lowest N minima found. Also, `callback` can be used to specify a user defined stop criterion by optionally returning True to stop the `basinhopping` routine.
- `interval`: integer, optional
  - interval for how often to update the `stepsize`.
- `disp`: bool, optional
  - Set to True to print status messages.
niter_success : integer, optional
Stop the run if the global minimum candidate remains the same for this number of
iterations.

seed : int or np.random.RandomState, optional
If seed is not specified the np.random.RandomState singleton is used. If seed is an int, a
new np.random.RandomState instance is used, seeded with seed. If seed is already a
np.random.RandomState instance, then that np.random.RandomState instance is used.
Specify seed for repeatable minimizations. The random numbers generated with this
seed only affect the default Metropolis accept_test and the default take_step. If you
supply your own take_step and accept_test, and these functions use random number
generation, then those functions are responsible for the state of their random number
generator.

Returns
res : OptimizeResult
The optimization result represented as a OptimizeResult object. Important at-
dtributes are: x the solution array, fun the value of the function at the solution, and
message which describes the cause of the termination. The OptimizeResult ob-
ject returned by the selected minimizer at the lowest minimum is also contained within
this object and can be accessed through the lowest_optimization_result at-
ttribute. See OptimizeResult for a description of other attributes.

See also:

minimize The local minimization function called once for each basinhopping step. minimizer_kwargs
is passed to this routine.

Notes

Basin-hopping is a stochastic algorithm which attempts to find the global minimum of a smooth scalar function
of one or more variables [R188] [R189] [R190] [R191]. The algorithm in its current form was described by

The algorithm is iterative with each cycle composed of the following features

1. random perturbation of the coordinates
2. local minimization
3. accept or reject the new coordinates based on the minimized function value

The acceptance test used here is the Metropolis criterion of standard Monte Carlo algorithms, although there are
many other possibilities [R190].

This global minimization method has been shown to be extremely efficient for a wide variety of problems in
physics and chemistry. It is particularly useful when the function has many minima separated by large barriers.
See the Cambridge Cluster Database http://www-wales.ch.cam.ac.uk/CCD.html for databases of molecular sys-
tems that have been optimized primarily using basin-hopping. This database includes minimization problems
exceeding 300 degrees of freedom.

See the free software program GMIN (http://www-wales.ch.cam.ac.uk/GMIN) for a Fortran implementation of
basin-hopping. This implementation has many different variations of the procedure described above, including
more advanced step taking algorithms and alternate acceptance criterion.

For stochastic global optimization there is no way to determine if the true global minimum has actually been
found. Instead, as a consistency check, the algorithm can be run from a number of different random starting
points to ensure the lowest minimum found in each example has converged to the global minimum. For this
reason basinhopping will by default simply run for the number of iterations niter and return the lowest
minimum found. It is left to the user to ensure that this is in fact the global minimum.
Choosing \textit{stepsize}: This is a crucial parameter in \texttt{basinhopping} and depends on the problem being solved. Ideally it should be comparable to the typical separation between local minima of the function being optimized. \texttt{basinhopping} will, by default, adjust \textit{stepsize} to find an optimal value, but this may take many iterations. You will get quicker results if you set a sensible value for \textit{stepsize}.

Choosing \textit{T}: The parameter \textit{T} is the temperature used in the metropolis criterion. Basinhopping steps are accepted with probability 1 if $\text{func}(x_{\text{new}}) < \text{func}(x_{\text{old}})$, or otherwise with probability:

$$
\exp\left( \frac{-\left(\text{func}(x_{\text{new}}) - \text{func}(x_{\text{old}})\right)}{T} \right)
$$

So, for best results, \textit{T} should be comparable to the typical difference in function values between local minima.

New in version 0.12.0.

\textbf{References}

[R188], [R189], [R190], [R191]

\textbf{Examples}

The following example is a one-dimensional minimization problem, with many local minima superimposed on a parabola.

```python
>>> from scipy.optimize import basinhopping
>>> func = lambda x: np.cos(14.5 * x - 0.3) + (x + 0.2) * x
>>> x0=[1.]
```

Basinhopping, internally, uses a local minimization algorithm. We will use the parameter \texttt{minimizer_kwargs} to tell \texttt{basinhopping} which algorithm to use and how to set up that minimizer. This parameter will be passed to \texttt{scipy.optimize.minimize()}.

```python
>>>
>>> minimizer_kwargs = {"method": "BFGS"}
>>> ret = basinhopping(func, x0, minimizer_kwargs=minimizer_kwargs,
...    niter=200)
>>> print(\"global minimum: x = %.4f, f(x0) = %.4f \" % (ret.x, ret.fun))
global minimum: x = -0.1951, f(x0) = -1.0009
```

Next consider a two-dimensional minimization problem. Also, this time we will use gradient information to significantly speed up the search.

```python
>>> def func2d(x):
...    f = np.cos(14.5 * x[0] - 0.3) + (x[1] + 0.2) * x[1] + (x[0] + 0.2) * x[0]
...    df = np.zeros(2)
...    df[0] = -14.5 * np.sin(14.5 * x[0] - 0.3) + 2. * x[0] + 0.2
...    df[1] = 2. * x[1] + 0.2
...    return f, df
```

We’ll also use a different local minimization algorithm. Also we must tell the minimizer that our function returns both energy and gradient (jacobian)

```python
>>> minimizer_kwargs = {"method":"L-BFGS-B", "jac":True}
>>> x0 = [1.0, 1.0]
>>> ret = basinhopping(func2d, x0, minimizer_kwargs=minimizer_kwargs,
...    niter=200)
>>> print("global minimum: x = [%.4f, %.4f], f(x0) = %.4f \" % (ret.x[0],
...    ret.x[1],
...    ret.fun))
global minimum: x = [-0.1951, -0.1000], f(x0) = -1.0109
```
Here is an example using a custom step taking routine. Imagine you want the first coordinate to take larger steps then the rest of the coordinates. This can be implemented like so:

```python
>>> class MyTakeStep(object):
...     def __init__(self, stepsize=0.5):
...         self.stepsize = stepsize
...     def __call__(self, x):
...         s = self.stepsize
...         x[0] += np.random.uniform(-2.*s, 2.*s)
...         x[1:] += np.random.uniform(-s, s, x[1:].shape)
...         return x
```

Since `MyTakeStep.stepsize` exists basinhopping will adjust the magnitude of `stepsize` to optimize the search. We’ll use the same 2-D function as before:

```python
>>> mytakestep = MyTakeStep()
>>> ret = basinhopping(func2d, x0, minimizer_kwargs=minimizer_kwargs,
...     niter=200, take_step=mytakestep)
>>> print("global minimum: x = \[%.4f, %.4f\], f(x0) = %.4f" % (ret.x[0],
...     ret.x[1],
...     ret.fun))
global minimum: x = [-0.1951, -0.1000], f(x0) = -1.0109
```

Now let’s do an example using a custom callback function which prints the value of every minimum found:

```python
>>> def print_fun(x, f, accepted):
...     print("at minimum %.4f accepted %d" % (f, int(accepted)))
```

We’ll run it for only 10 basinhopping steps this time.

```python
>>> np.random.seed(1)
>>> ret = basinhopping(func2d, x0, minimizer_kwargs=minimizer_kwargs,
...     niter=10, callback=print_fun)
```

The minimum at -1.0109 is actually the global minimum, found already on the 8th iteration.

Now let’s implement bounds on the problem using a custom `accept_test`:

```python
>>> class MyBounds(object):
...     def __init__(self, xmax=[1.1,1.1], xmin=[-1.1,-1.1] ):
...         self.xmax = np.array(xmax)
...         self.xmin = np.array(xmin)
...     def __call__(self, **kwargs):
...         x = kwargs["x_new"]
...         tmax = bool(np.all(x <= self.xmax))
...         tmin = bool(np.all(x >= self.xmin))
...         return tmax and tmin
```
```python
>>> mybounds = MyBounds()
>>> ret = basinhopping(func2d, x0, minimizer_kwargs=minimizer_kwars,
... niter=10, accept_test=mybounds)
```

```
scipy.optimize.brute(func, ranges, args=(), Ns=20, full_output=0, finish=<function fmin>,
            disp=False)
```

Minimize a function over a given range by brute force.

Uses the “brute force” method, i.e. computes the function’s value at each point of a multidimensional grid of points, to find the global minimum of the function.

The function is evaluated everywhere in the range with the datatype of the first call to the function, as enforced by the vectorize NumPy function. The value and type of the function evaluation returned when `full_output=True` are affected in addition by the `finish` argument (see Notes).

**Parameters**

- **func**: callable
  The objective function to be minimized. Must be in the form $f(x, *args)$, where $x$ is the argument in the form of a 1-D array and $args$ is a tuple of any additional fixed parameters needed to completely specify the function.

- **ranges** : tuple
  Each component of the `ranges` tuple must be either a “slice object” or a range tuple of the form `(low, high)`. The program uses these to create the grid of points on which the objective function will be computed. See Note 2 for more detail.

- **args** : tuple, optional
  Any additional fixed parameters needed to completely specify the function.

- **Ns** : int, optional
  Number of grid points along the axes, if not otherwise specified. See Note 2.

- **full_output** : bool, optional
  If True, return the evaluation grid and the objective function’s values on it.

- **finish** : callable, optional
  An optimization function that is called with the result of brute force minimization as initial guess. `finish` should take `func` and the initial guess as positional arguments, and take `args` as keyword arguments. It may additionally take `full_output` and/or `disp` as keyword arguments. Use None if no “polishing” function is to be used. See Notes for more details.

- **disp** : bool, optional
  Set to True to print convergence messages.

**Returns**

- **x0** : ndarray
  A 1-D array containing the coordinates of a point at which the objective function had its minimum value. (See Note 1 for which point is returned.)

- **fval** : float
  Function value at the point $x0$. (Returned when `full_output` is True.)

- **grid** : tuple
  Representation of the evaluation grid. It has the same length as $x0$. (Returned when `full_output` is True.)

- **Jout** : ndarray
  Function values at each point of the evaluation grid, i.e., $Jout = func(*grid)$. (Returned when `full_output` is True.)

See also:

- `basinhopping`, `differential_evolution`

**Notes**

**Note 1**: The program finds the gridpoint at which the lowest value of the objective function occurs. If `finish` is None, that is the point returned. When the global minimum occurs within (or not very far outside) the grid’s
boundaries, and the grid is fine enough, that point will be in the neighborhood of the global minimum.

However, users often employ some other optimization program to “polish” the gridpoint values, i.e., to seek a more precise (local) minimum near brute's best gridpoint. The brute function’s finish option provides a convenient way to do that. Any polishing program used must take brute’s output as its initial guess as a positional argument, and take brute’s input values for args as keyword arguments, otherwise an error will be raised. It may additionally take full_output and/or disp as keyword arguments.

brute assumes that the finish function returns either an OptimizeResult object or a tuple in the form: (xmin, Jmin, ..., statuscode), where xmin is the minimizing value of the argument, Jmin is the minimum value of the objective function, “...” may be some other returned values (which are not used by brute), and statuscode is the status code of the finish program.

Note that when finish is not None, the values returned are those of the finish program, not the gridpoint ones. Consequently, while brute confines its search to the input grid points, the finish program’s results usually will not coincide with any gridpoint, and may fall outside the grid’s boundary. Thus, if a minimum only needs to be found over the provided grid points, make sure to pass in finish= None.

Note 2: The grid of points is a numpy.mgrid object. For brute the ranges and Ns inputs have the following effect. Each component of the ranges tuple can be either a slice object or a two-tuple giving a range of values, such as (0, 5). If the component is a slice object, brute uses it directly. If the component is a two-tuple range, brute internally converts it to a slice object that interpolates Ns points from its low-value to its high-value, inclusive.

Examples

We illustrate the use of brute to seek the global minimum of a function of two variables that is given as the sum of a positive-definite quadratic and two deep “Gaussian-shaped” craters. Specifically, define the objective function f as the sum of three other functions, f = f1 + f2 + f3. We suppose each of these has a signature (z, *params), where z = (x, y), and params and the functions are as defined below.

```python
def f1(z, *params):
    x, y = z
    a, b, c, d, e, f, g, h, i, j, k, l, scale = params
    return (a * x**2 + b * x * y + c * y**2 + d*x + e*y + f)

def f2(z, *params):
    x, y = z
    a, b, c, d, e, f, g, h, i, j, k, l, scale = params
    return (-g*np.exp(-((x-h)**2 + (y-i)**2) / scale))

def f3(z, *params):
    x, y = z
    a, b, c, d, e, f, g, h, i, j, k, l, scale = params
    return (-j*np.exp(-((x-k)**2 + (y-l)**2) / scale))

def f(z, *params):
    return f1(z, *params) + f2(z, *params) + f3(z, *params)
```

Thus, the objective function may have local minima near the minimum of each of the three functions of which it is composed. To use fmin to polish its gridpoint result, we may then continue as follows:

```python
>>> rranges = (slice(-4, 4, 0.25), slice(-4, 4, 0.25))
>>> from scipy import optimize
>>> resbrute = optimize.brute(f, rranges, args=params, full_output=True,
                              finish=optimize.fmin)
>>> resbrute[0]  # global minimum
```

5.18. Optimization and root finding (scipy.optimize)
array([-1.05665192, 1.80834843])

>>> resbrute[1]  # function value at global minimum
-3.4085818767

Note that if finish had been set to None, we would have gotten the gridpoint [-1.0 1.75] where the rounded function value is -2.892.

**Rosenbrock function**

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rosen(x)</td>
<td>The Rosenbrock function.</td>
</tr>
<tr>
<td>rosen_der(x)</td>
<td>The derivative (i.e. gradient) of the Rosenbrock function.</td>
</tr>
<tr>
<td>rosen_hess(x)</td>
<td>The Hessian matrix of the Rosenbrock function.</td>
</tr>
<tr>
<td>rosen_hess_prod(x, p)</td>
<td>Product of the Hessian matrix of the Rosenbrock function with a vector.</td>
</tr>
</tbody>
</table>

```python
scipy.optimize.rosen(x)
```

The Rosenbrock function.

The function computed is:

\[
\text{sum}(100.0 \times (x[1:] - x[:-1] \times 2.0)^2 + (1 - x[:-1] \times 2.0)^2)
\]

**Parameters**

- `x`: array_like
  - 1-D array of points at which the Rosenbrock function is to be computed.

**Returns**

- `f`: float
  - The value of the Rosenbrock function.

See also:

- rosen_der, rosen_hess, rosen_hess_prod

```python
scipy.optimize.rosen_der(x)
```

The derivative (i.e. gradient) of the Rosenbrock function.

**Parameters**

- `x`: array_like
  - 1-D array of points at which the derivative is to be computed.

**Returns**

- `rosen_der`: (N,) ndarray
  - The gradient of the Rosenbrock function at `x`.

See also:

- rosen, rosen_hess, rosen_hess_prod

```python
scipy.optimize.rosen_hess(x)
```

The Hessian matrix of the Rosenbrock function.

**Parameters**

- `x`: array_like
  - 1-D array of points at which the Hessian matrix is to be computed.

**Returns**

- `rosen_hess`: ndarray
  - The Hessian matrix of the Rosenbrock function at `x`.

See also:

- rosen, rosen_der, rosen_hess_prod

```python
scipy.optimize.rosen_hess_prod(x, p)
```

Product of the Hessian matrix of the Rosenbrock function with a vector.
Parameters

- **x**: array_like
  - 1-D array of points at which the Hessian matrix is to be computed.
- **p**: array_like
  - 1-D array, the vector to be multiplied by the Hessian matrix.

Returns

- **rosen_hess_prod**: ndarray
  - The Hessian matrix of the Rosenbrock function at \( x \) multiplied by the vector \( p \).

See also:

- `rosen`, `rosen_der`, `rosen_hess`

5.18.2 Fitting

```python
scipy.optimize.curve_fit(f, xdata, ydata[, p0, sigma, ...])
```

Use non-linear least squares to fit a function, \( f \), to data.

**Parameters**

- **f**: callable
  - The model function, \( f(x, ...) \). It must take the independent variable as the first argument and the parameters to fit as separate remaining arguments.

- **xdata**: An M-length sequence or an (k,M)-shaped array for functions with k predictors
  - The independent variable where the data is measured.

- **ydata**: M-length sequence
  - The dependent data — nominally \( f(xdata, ...) \)

- **p0**: None, scalar, or N-length sequence, optional
  - Initial guess for the parameters. If None, then the initial values will all be 1 (if the number of parameters for the function can be determined using introspection, otherwise a ValueError is raised).

- **sigma**: None or M-length sequence or MxM array, optional
  - Determines the uncertainty in \( ydata \). If we define residuals as \( r = ydata - f(xdata, *popt) \), then the interpretation of \( sigma \) depends on its number of dimensions:
    - A 1-d \( sigma \) should contain values of standard deviations of errors in \( ydata \). In this case, the optimized function is \( chisq = \text{sum}((r / sigma) ** 2) \).
    - A 2-d \( sigma \) should contain the covariance matrix of errors in \( ydata \). In this case, the optimized function is \( chisq = r.T @ inv(sigma) @ r \).
  
  New in version 0.19.

- **absolute_sigma**: bool, optional
  - If True, \( sigma \) is used in an absolute sense and the estimated parameter covariance \( pcov \) reflects these absolute values.
  - If False, only the relative magnitudes of the \( sigma \) values matter. The returned parameter covariance matrix \( pcov \) is based on scaling \( sigma \) by a constant factor. This constant is set by demanding that the reduced \( chisq \) for the optimal parameters \( popt \) when using the scaled \( sigma \) equals unity. In other words, \( sigma \) is scaled to match the sample variance of the residuals after the fit. Mathematically, \( pcov(absolute\_sigma=False) = pcov(absolute\_sigma=True) * chisq(popt)/(M-N) \).

- **check_finite**: bool, optional

5.18. Optimization and root finding (`scipy.optimize`)
If True, check that the input arrays do not contain nans of infs, and raise a ValueError if they do. Setting this parameter to False may silently produce nonsensical results if the input arrays do contain nans. Default is True.

**bounds**: 2-tuple of array_like, optional
Lower and upper bounds on independent variables. Defaults to no bounds. Each element of the tuple must be either an array with the length equal to the number of parameters, or a scalar (in which case the bound is taken to be the same for all parameters.) Use np.inf with an appropriate sign to disable bounds on all or some parameters.
New in version 0.17.

**method**: {'lm', 'trf', 'dogbox'}, optional
Method to use for optimization. See *least_squares* for more details. Default is ‘lm’ for unconstrained problems and ‘trf’ if *bounds* are provided. The method ‘lm’ won’t work when the number of observations is less than the number of variables, use ‘trf’ or ‘dogbox’ in this case.
New in version 0.17.

**jac**: callable, string or None, optional
Function with signature *jac(x, ...)* which computes the Jacobian matrix of the model function with respect to parameters as a dense array_like structure. It will be scaled according to provided *sigma*. If None (default), the Jacobian will be estimated numerically. String keywords for ‘trf’ and ‘dogbox’ methods can be used to select a finite difference scheme, see *least_squares*.
New in version 0.18.

**kwargs**
Keyword arguments passed to *leastsq* for method='lm' or *least_squares* otherwise.

**Returns**

**popt**: array
Optimal values for the parameters so that the sum of the squared residuals of \( f(xdata, \cdot popt) - ydata \) is minimized

**pcov**: 2d array
The estimated covariance of popt. The diagonals provide the variance of the parameter estimate. To compute one standard deviation errors on the parameters use *perr = np.sqrt(np.diag(pcov))*. How the *sigma* parameter affects the estimated covariance depends on *absolute_sigma* argument, as described above.

If the Jacobian matrix at the solution doesn’t have a full rank, then ‘lm’ method returns a matrix filled with np.inf, on the other hand ‘trf’ and ‘dogbox’ methods use Moore-Penrose pseudoinverse to compute the covariance matrix.

**Raises**

**ValueError**
if either *ydata* or *xdata* contain NaNs, or if incompatible options are used.

**RuntimeError**
if the least-squares minimization fails.

**OptimizeWarning**
if covariance of the parameters can not be estimated.

**See also:**

*least_squares*
Minimize the sum of squares of nonlinear functions.

*scipy.stats.linregress*
Calculate a linear least squares regression for two sets of measurements.
Notes

With `method='lm'`, the algorithm uses the Levenberg-Marquardt algorithm through `leastsq`. Note that this algorithm can only deal with unconstrained problems.

Box constraints can be handled by methods ‘trf’ and ‘dogbox’. Refer to the docstring of `least_squares` for more information.

Examples

```python
>>> import numpy as np
>>> import matplotlib.pyplot as plt
>>> from scipy.optimize import curve_fit

>>> def func(x, a, b, c):
... return a * np.exp(-b * x) + c

Define the data to be fit with some noise:

```python
>>> xdata = np.linspace(0, 4, 50)
>>> y = func(xdata, 2.5, 1.3, 0.5)
>>> np.random.seed(1729)
>>> y_noise = 0.2 * np.random.normal(size=xdata.size)
>>> ydata = y + y_noise
>>> plt.plot(xdata, ydata, 'b-', label='data')
```

Fit for the parameters `a`, `b`, `c` of the function `func`:

```python
>>> popt, pcov = curve_fit(func, xdata, ydata)
>>> popt
array([ 2.55423706, 1.35190947, 0.47450618])
>>> plt.plot(xdata, func(xdata, *popt), 'r-',
... label='fit: a=%5.3f, b=%5.3f, c=%5.3f' % tuple(popt))
```

Constrain the optimization to the region of `0 <= a <= 3`, `0 <= b <= 1` and `0 <= c <= 0.5`:

```python
>>> popt, pcov = curve_fit(func, xdata, ydata, bounds=(0, [3., 1., 0.5]))
>>> popt
array([2.43708906, 1. , 0.35015434])
>>> plt.plot(xdata, func(xdata, *popt), 'g--',
... label='fit: a=%5.3f, b=%5.3f, c=%5.3f' % tuple(popt))
```

```python
>>> plt.xlabel('x')
>>> plt.ylabel('y')
>>> plt.legend()
>>> plt.show()
```
5.18.3 Root finding

Scalar functions

```python
brentq(f, a, b[, args, xtol, rtol, maxiter, ...])
```

Find a root of a function in a bracketing interval using Brent’s method.

Uses the classic Brent’s method to find a zero of the function \( f \) on the sign changing interval \([a, b]\). Generally considered the best of the rootfinding routines here. It is a safe version of the secant method that uses inverse quadratic extrapolation. Brent’s method combines root bracketing, interval bisection, and inverse quadratic interpolation. It is sometimes known as the van Wijngaarden-Dekker-Brent method. Brent (1973) claims convergence is guaranteed for functions computable within \([a, b]\).

[Brent1973] provides the classic description of the algorithm. Another description can be found in a recent edition of Numerical Recipes, including [PressEtal1992]. Another description is at http://mathworld.wolfram.com/BrentsMethod.html. It should be easy to understand the algorithm just by reading our code. Our code diverges a bit from standard presentations: we choose a different formula for the extrapolation step.

**Parameters**

- \( f \) : function
  - Python function returning a number. The function \( f \) must be continuous, and \( f(a) \) and \( f(b) \) must have opposite signs.
- \( a \) : number
  - One end of the bracketing interval \([a, b]\).
- \( b \) : number
  - The other end of the bracketing interval \([a, b]\).
- \( xtol \) : number, optional
  - Precision goal; if \( x \) is within \( xtol \) of a root, convergence is declared.
- \( rtol \) : number
  - Relative tolerance; if \( ||x_{new} - x_{old}|| \leq rtol \cdot ||x_{old}|| \) convergence is declared.
- \( maxiter \) : integer
  - The maximum number of iterations.
```

`scipy.optimize.brentq(f, a, b, args=(), xtol=2e-12, rtol=8.881784197001252e-16, maxiter=100, full_output=False, disp=True)`

Find a root of a function in a bracketing interval using Brent’s method.

Uses the classic Brent’s method to find a zero of the function \( f \) on the sign changing interval \([a, b]\). Generally considered the best of the rootfinding routines here. It is a safe version of the secant method that uses inverse quadratic extrapolation. Brent’s method combines root bracketing, interval bisection, and inverse quadratic interpolation. It is sometimes known as the van Wijngaarden-Dekker-Brent method. Brent (1973) claims convergence is guaranteed for functions computable within \([a, b]\).

[Brent1973] provides the classic description of the algorithm. Another description can be found in a recent edition of Numerical Recipes, including [PressEtal1992]. Another description is at http://mathworld.wolfram.com/BrentsMethod.html. It should be easy to understand the algorithm just by reading our code. Our code diverges a bit from standard presentations: we choose a different formula for the extrapolation step.
The computed root $x_0$ will satisfy $\text{np.allclose}(x, x_0, \text{atol}=\text{xtol}, \text{rtol}=\text{rtol})$, where $x$ is the exact root. The parameter must be nonnegative. For nice functions, Brent's method will often satisfy the above condition with $\text{xtol}/2$ and $\text{rtol}/2$. [Brent1973]

**rtol** : number, optional
The computed root $x_0$ will satisfy $\text{np.allclose}(x, x_0, \text{atol}=\text{xtol}, \text{rtol}=\text{rtol})$, where $x$ is the exact root. The parameter cannot be smaller than its default value of $4*\text{np.info(float).eps}$. For nice functions, Brent’s method will often satisfy the above condition with $\text{xtol}/2$ and $\text{rtol}/2$. [Brent1973]

**maxiter** : number, optional
if convergence is not achieved in maxiter iterations, an error is raised. Must be $\geq 0$.

**args** : tuple, optional
containing extra arguments for the function $f$. $f$ is called by $\text{apply}(f, (x)+\text{args})$.

**full_output** : bool, optional
If $\text{full_output}$ is False, the root is returned. If $\text{full_output}$ is True, the return value is $(x, r)$, where $x$ is the root, and $r$ is a RootResults object.

**disp** : bool, optional
If True, raise RuntimeError if the algorithm didn’t converge.

**Returns**

- $x_0$ : float
  Zero of $f$ between $a$ and $b$.
- $r$ : RootResults (present if $\text{full_output} = \text{True}$)
  Object containing information about the convergence. In particular, $r.\text{converged}$ is True if the routine converged.

**Examples**

```python
>>> def f(x):
...   return (x**2 - 1)
```
```python
>>> from scipy import optimize

```SciPy optimize.brenth(f, a, b, args=(), xtol=2e-12, rtol=8.8817841970012523e-16, maxiter=100, full_output=False, disp=True)

Find root of f in [a,b].

A variation on the classic Brent routine to find a zero of the function f between the arguments a and b that uses hyperbolic extrapolation instead of inverse quadratic extrapolation. There was a paper back in the 1980’s ... f(a) and f(b) cannot have the same signs. Generally on a par with the brent routine, but not as heavily tested. It is a safe version of the secant method that uses hyperbolic extrapolation. The version here is by Chuck Harris.

**Parameters**

- **f**: function
  - Python function returning a number. f must be continuous, and f(a) and f(b) must have opposite signs.
- **a**: number
  - One end of the bracketing interval [a,b].
- **b**: number
  - The other end of the bracketing interval [a,b].
- **xtol**: number, optional
  - The computed root x0 will satisfy np.allclose(x, x0, atol=xtol, rtol=rtol), where x is the exact root. The parameter must be nonnegative. As with brentq, for nice functions the method will often satisfy the above condition with xtol/2 and rtol/2.
- **rtol**: number, optional
  - The computed root x0 will satisfy np.allclose(x, x0, atol=xtol, rtol=rtol), where x is the exact root. The parameter cannot be smaller than its default value of 4*np.finfo(float).eps. As with brentq, for nice functions the method will often satisfy the above condition with xtol/2 and rtol/2.
- **maxiter**: number, optional
  - if convergence is not achieved in maxiter iterations, an error is raised. Must be >= 0.
- **args**: tuple, optional
  - containing extra arguments for the function f. f is called by apply(f, (x)+args).
- **full_output**: bool, optional
  - If full_output is False, the root is returned. If full_output is True, the return value is (x, r), where x is the root, and r is a RootResults object.
- **disp**: bool, optional
  - If True, raise RuntimeError if the algorithm didn’t converge.

**Returns**

- **x0**: float
  - Zero of f between a and b.
- **r**: RootResults (present if full_output = True)
  - Object containing information about the convergence. In particular, r.converged is True if the routine converged.

1036 Chapter 5. API Reference
Examples

```python
>>> def f(x):
...     return (x**2 - 1)

>>> from scipy import optimize

>>> root = optimize.brenth(f, -2, 0)
>>> root
-1.0

>>> root = optimize.brenth(f, 0, 2)
>>> root
1.0
```

scipy.optimize.ridder \( f, a, b, \text{args}=(,) \), \( \text{xtol}=2e-12 \), \( \text{rtol}=8.8817841970012523e-16 \), \( \text{maxiter}=100 \),
\( \text{full_output}=False, \text{disp}=True \)

Find a root of a function in an interval.

**Parameters**

\( f \) : function

Python function returning a number. \( f \) must be continuous, and \( f(a) \) and \( f(b) \) must have opposite signs.

\( a \) : number

One end of the bracketing interval [a,b].

\( b \) : number

The other end of the bracketing interval [a,b].

\( \text{xtol} \) : number, optional

The computed root \( x_0 \) will satisfy \( \text{np.allclose}(x, x_0, \text{atol}=\text{xtol}, \text{rtol}=\text{rtol}) \), where \( x \) is the exact root. The parameter must be nonnegative.

\( \text{rtol} \) : number, optional

The computed root \( x_0 \) will satisfy \( \text{np.allclose}(x, x_0, \text{atol}=\text{xtol}, \text{rtol}=\text{rtol}) \), where \( x \) is the exact root. The parameter cannot be smaller than its default value of \( 4*\text{np.finfo(float).eps} \).

\( \text{maxiter} \) : number, optional

if convergence is not achieved in maxiter iterations, an error is raised. Must be \( \geq 0 \).

\( \text{args} \) : tuple, optional

containing extra arguments for the function \( f. f \) is called by \( \text{apply}(f, (x)+\text{args}) \).

\( \text{full_output} \) : bool, optional

If \( \text{full_output} \) is False, the root is returned. If \( \text{full_output} \) is True, the return value is \( (x, r) \), where \( x \) is the root, and \( r \) is a RootResults object.

\( \text{disp} \) : bool, optional

If True, raise RuntimeError if the algorithm didn’t converge.

**Returns**

\( x_0 \) : float

Zero of \( f \) between \( a \) and \( b \).

\( r \) : RootResults (present if \( \text{full_output} = \text{True} \)
Object containing information about the convergence. In particular, `r.converged` is True if the routine converged.

`fixed_point`

scalar fixed-point finder

Notes

Uses [Ridders1979] method to find a zero of the function \( f \) between the arguments \( a \) and \( b \). Ridders’ method is faster than bisection, but not generally as fast as the Brent routines. [Ridders1979] provides the classic description and source of the algorithm. A description can also be found in any recent edition of Numerical Recipes.

The routine used here diverges slightly from standard presentations in order to be a bit more careful of tolerance.

References

[Ridders1979]

Examples

```python
>>> def f(x):
...     return (x**2 - 1)

>>> from scipy import optimize

>>> root = optimize.ridder(f, 0, 2)
>>> root
1.0

>>> root = optimize.ridder(f, -2, 0)
>>> root
-1.0
```

scipy.optimize.bisect(f, a, b, args=(), xtol=2e-12, rtol=8.8817841970012523e-16, maxiter=100, full_output=False, disp=True)

Find root of a function within an interval.

Basic bisection routine to find a zero of the function \( f \) between the arguments \( a \) and \( b \). \( f(a) \) and \( f(b) \) cannot have the same signs. Slow but sure.

Parameters

- **f**: function
  - Python function returning a number. \( f \) must be continuous, and \( f(a) \) and \( f(b) \) must have opposite signs.
- **a**: number
  - One end of the bracketing interval \([a, b]\).
- **b**: number
  - The other end of the bracketing interval \([a, b]\).
- **xtol**: number, optional
  - The computed root \( x_0 \) will satisfy \( \text{np.allclose}(x, x_0, \text{atol}=\text{xtol}, \text{rtol}=\text{rtol}) \), where \( x \) is the exact root. The parameter must be nonnegative.
- **rtol**: number, optional
  - The computed root \( x_0 \) will satisfy \( \text{np.allclose}(x, x_0, \text{atol}=\text{xtol}, \text{rtol}=\text{rtol}) \), where \( x \) is the exact root. The parameter cannot be smaller than its default value of \( 4 \times \text{np.finfo(float).eps} \).
**maxiter**: number, optional
if convergence is not achieved in maxiter iterations, an error is raised. Must be &gt;= 0.

**args**: tuple, optional
containing extra arguments for the function f. f is called by apply(f, (x)+args).

**full_output**: bool, optional
If full_output is False, the root is returned. If full_output is True, the return value is (x, r), where x is the root, and r is a RootResults object.

**disp**: bool, optional
If True, raise RuntimeError if the algorithm didn’t converge.

**Returns**
x0: float
Zero of f between a and b.

r: RootResults (present if full_output = True)
Object containing information about the convergence. In particular, r.converged is True if the routine converged.

```

**scipy.optimize.newton** (func, x0, fprime=None, args=(), tol=1.48e-08, maxiter=50, fprime2=None)
Find a zero using the Newton-Raphson or secant method.

Find a zero of the function func given a nearby starting point x0. The Newton-Raphson method is used if the derivative fprime of func is provided, otherwise the secant method is used. If the second order derivative fprime2 of func is provided, parabolic Halley’s method is used.

**Parameters**

**func**: function
The function whose zero is wanted. It must be a function of a single variable of the form f(x,a,b,c...), where a,b,c... are extra arguments that can be passed in the args parameter.

**x0**: float
An initial estimate of the zero that should be somewhere near the actual zero.

**fprime**: function, optional
The derivative of the function when available and convenient. If it is None (default), then the secant method is used.

**args**: tuple, optional
Extra arguments to be used in the function call.
tol : float, optional
    The allowable error of the zero value.
maxiter : int, optional
    Maximum number of iterations.
fprime2 : function, optional
    The second order derivative of the function when available and convenient. If it is None (default), then the normal Newton-Raphson or the secant method is used. If it is given, parabolic Halley’s method is used.

Returns
zero : float
    Estimated location where function is zero.

See also:
brentq, brent, ridder, bisect

fsolve     find zeroes in n dimensions.

Notes
The convergence rate of the Newton-Raphson method is quadratic, the Halley method is cubic, and the secant method is sub-quadratic. This means that if the function is well behaved the actual error in the estimated zero is approximately the square (cube for Halley) of the requested tolerance up to roundoff error. However, the stopping criterion used here is the step size and there is no guarantee that a zero has been found. Consequently the result should be verified. Safer algorithms are brentq, brent, ridder, and bisect, but they all require that the root first be bracketed in an interval where the function changes sign. The brentq algorithm is recommended for general use in one dimensional problems when such an interval has been found.

Examples

```python
>>> def f(x):
...     return (x**3 - 1)  # only one real root at x = 1

>>> from scipy import optimize

fprime and fprime2 not provided, use secant method

>>> root = optimize.newton(f, 1.5)
>>> root
1.0000000000000016

Only fprime provided, use Newton Raphson method

>>> root = optimize.newton(f, 1.5, fprime=lambda x: 3 * x**2)
>>> root
1.0

fprime2 provided, fprime provided/not provided use parabolic Halley’s method

>>> root = optimize.newton(f, 1.5, fprime2=lambda x: 6 * x)
>>> root
1.0000000000000016
>>> root = optimize.newton(f, 1.5, fprime=lambda x: 3 * x**2,
...                         fprime2=lambda x: 6 * x)
>>> root
1.0

Fixed point finding:
SciPy Reference Guide, Release 1.0.0

fixed_point(func, x0[, args, xtol, maxiter, ...])

Find a fixed point of the function.

scipy.optimize.fixed_point(func, x0, args=(), xtol=1e-08, maxiter=500, method=’del2’)
Find a fixed point of the function.
Given a function of one or more variables and a starting point, find a fixed-point of the function: i.e. where
func(x0) == x0.
Parameters

func : function
Function to evaluate.
x0 : array_like
Fixed point of function.
args : tuple, optional
Extra arguments to func.
xtol : float, optional
Convergence tolerance, defaults to 1e-08.
maxiter : int, optional
Maximum number of iterations, defaults to 500.
method : {“del2”, “iteration”}, optional
Method of finding the fixed-point, defaults to “del2” which uses Steffensen’s Method
with Aitken’s Del^2 convergence acceleration [R197]. The “iteration” method simply
iterates the function until convergence is detected, without attempting to accelerate the
convergence.

References
[R197]
Examples
>>> from scipy import optimize
>>> def func(x, c1, c2):
...
return np.sqrt(c1/(x+c2))
>>> c1 = np.array([10,12.])
>>> c2 = np.array([3, 5.])
>>> optimize.fixed_point(func, [1.2, 1.3], args=(c1,c2))
array([ 1.4920333 , 1.37228132])

Multidimensional
General nonlinear solvers:
root(fun, x0[, args, method, jac, tol, ...])
fsolve(func, x0[, args, fprime, ...])
broyden1(F, xin[, iter, alpha, ...])
broyden2(F, xin[, iter, alpha, ...])

Find a root of a vector function.
Find the roots of a function.
Find a root of a function, using Broyden’s first Jacobian
approximation.
Find a root of a function, using Broyden’s second Jacobian
approximation.

scipy.optimize.root(fun, x0, args=(), method=’hybr’, jac=None, tol=None, callback=None, options=None)
Find a root of a vector function.
Parameters

fun : callable

5.18. Optimization and root finding (scipy.optimize)

1041


A vector function to find a root of.

\textbf{x0} : ndarray
Initial guess.

\textbf{args} : tuple, optional
Extra arguments passed to the objective function and its Jacobian.

\textbf{method} : str, optional
Type of solver. Should be one of
• ‘hybr’ (see here)
• ‘lm’ (see here)
• ‘broyden1’ (see here)
• ‘broyden2’ (see here)
• ‘anderson’ (see here)
• ‘linearmixing’ (see here)
• ‘diagbroyden’ (see here)
• ‘excitingmixing’ (see here)
• ‘krylov’ (see here)
• ‘df-sane’ (see here)

\textbf{jac} : bool or callable, optional
If \textbf{jac} is a Boolean and is True, \textbf{fun} is assumed to return the value of Jacobian along with the objective function. If False, the Jacobian will be estimated numerically. \textbf{jac} can also be a callable returning the Jacobian of \textbf{fun}. In this case, it must accept the same arguments as \textbf{fun}.

\textbf{tol} : float, optional
Tolerance for termination. For detailed control, use solver-specific options.

\textbf{callback} : function, optional
Optional callback function. It is called on every iteration as \textbf{callback(x, f)} where \textbf{x} is the current solution and \textbf{f} the corresponding residual. For all methods but ‘hybr’ and ‘lm’.

\textbf{options} : dict, optional
A dictionary of solver options. E.g. \textbf{xtol} or \textbf{maxiter}, see \textit{show_options()} for details.

\textbf{Returns} \textbf{sol} : OptimizeResult
The solution represented as a OptimizeResult object. Important attributes are:
\textbf{x} the solution array, \textbf{success} a Boolean flag indicating if the algorithm exited successfully and \textbf{message} which describes the cause of the termination. See \textit{OptimizeResult} for a description of other attributes.

\textbf{See also:}

\textit{show_options}
Additional options accepted by the solvers

\textbf{Notes}
This section describes the available solvers that can be selected by the ‘method’ parameter. The default method is \textit{hybr}.

Method \textit{hybr} uses a modification of the Powell hybrid method as implemented in MINPACK \cite{R221}.

Method \textit{lm} solves the system of nonlinear equations in a least squares sense using a modification of the Levenberg-Marquardt algorithm as implemented in MINPACK \cite{R221}.

Method \textit{df-sane} is a derivative-free spectral method. \cite{R223}

Methods \textit{broyden1}, \textit{broyden2}, \textit{anderson}, \textit{linearmixing}, \textit{diagbroyden}, \textit{excitingmixing}, \textit{krylov} are inexact Newton methods, with backtracking or full line searches \cite{R222}. Each method corresponds to a particular Jacobian approximations. See \textit{nonlin} for details.
• Method \texttt{broyden1} uses Broyden’s first Jacobian approximation, it is known as Broyden’s good method.
• Method \texttt{broyden2} uses Broyden’s second Jacobian approximation, it is known as Broyden’s bad method.
• Method \texttt{anderson} uses (extended) Anderson mixing.
• Method \texttt{Krylov} uses Krylov approximation for inverse Jacobian. It is suitable for large-scale problem.
• Method \texttt{diagbroyden} uses diagonal Broyden Jacobian approximation.
• Method \texttt{linearmixing} uses a scalar Jacobian approximation.
• Method \texttt{excitingmixing} uses a tuned diagonal Jacobian approximation.

**Warning:** The algorithms implemented for methods \texttt{diagbroyden}, \texttt{linearmixing} and \texttt{excitingmixing} may be useful for specific problems, but whether they will work may depend strongly on the problem.

New in version 0.11.0.

**Examples**
The following functions define a system of nonlinear equations and its jacobian.

```python
>>> def fun(x):
...     return [x[0] + 0.5 * (x[0] - x[1])**3 - 1.0,
...             0.5 * (x[1] - x[0])**3 + x[1]]

>>> def jac(x):
...     return np.array([[1 + 1.5 * (x[0] - x[1])**2,
...                       -1.5 * (x[0] - x[1])**2, 0,
...                       1 + 1.5 * (x[1] - x[0])**2]])
```

A solution can be obtained as follows.

```python
>>> from scipy import optimize
>>> sol = optimize.root(fun, [0, 0], jac=jac, method='hybr')
>>> sol.x
array([ 0.8411639, 0.1588361])
```

\texttt{scipy.optimize.fsolve} (\texttt{func}, \texttt{x0}, \texttt{args}(), \texttt{fprime}=None, \texttt{full_output}=0, \texttt{col_deriv}=0, \texttt{xtol}=1.49012e-08, \texttt{maxfev}=0, \texttt{band}=None, \texttt{epsfcn}=None, \texttt{factor}=100, \texttt{diag}=None)

Find the roots of a function.

Return the roots of the (non-linear) equations defined by \texttt{func(x) = 0} given a starting estimate.

**Parameters**
\texttt{func} : callable \texttt{f(x, \*args)}
A function that takes at least one (possibly vector) argument.
\texttt{x0} : \texttt{ndarray}
The starting estimate for the roots of \texttt{func(x) = 0}.
\texttt{args} : tuple, optional
Any extra arguments to \texttt{func}.
\texttt{fprime} : callable \texttt{f(x, \*args)}, optional
A function to compute the Jacobian of \texttt{func} with derivatives across the rows. By default, the Jacobian will be estimated.
**full_output**: bool, optional

If True, return optional outputs.

**col_deriv**: bool, optional

Specify whether the Jacobian function computes derivatives down the columns (faster, because there is no transpose operation).

**xtol**: float, optional

The calculation will terminate if the relative error between two consecutive iterates is at most xtol.

**maxfev**: int, optional

The maximum number of calls to the function. If zero, then 100*(N+1) is the maximum where N is the number of elements in x0.

**band**: tuple, optional

If set to a two-sequence containing the number of sub- and super-diagonals within the band of the Jacobi matrix, the Jacobi matrix is considered banded (only for fprime=None).

**epsfcn**: float, optional

A suitable step length for the forward-difference approximation of the Jacobian (for fprime=None). If epsfcn is less than the machine precision, it is assumed that the relative errors in the functions are of the order of the machine precision.

**factor**: float, optional

A parameter determining the initial step bound (factor * || diag * x||). Should be in the interval (0.1, 100).

**diag**: sequence, optional

N positive entries that serve as a scale factors for the variables.

**Returns**

- **x**: ndarray
  The solution (or the result of the last iteration for an unsuccessful call).

- **infodict**: dict
  A dictionary of optional outputs with the keys:
  - **nfev**: number of function calls
  - **njev**: number of Jacobian calls
  - **fvec**: function evaluated at the output
  - **fjac**: the orthogonal matrix, q, produced by the QR factorization of the final approximate Jacobian matrix, stored column wise
  - **r**: upper triangular matrix produced by QR factorization of the same matrix
  - **qtf**: the vector (transpose(q) * fvec)

- **ier**: int
  An integer flag. Set to 1 if a solution was found, otherwise refer to msg for more information.

- **mesg**: str
  If no solution is found, mesg details the cause of failure.

**See also**:

- **root**: Interface to root finding algorithms for multivariate functions.

**Notes**

fsolve is a wrapper around MINPACK’s hybrd and hybrj algorithms.

```python
scipy.optimize.broyden1(F, xin, iter=None, alpha=None, reduction_method='restart',
max_rank=None, verbose=False, maxiter=None, f_tol=None, f_rtol=None, x_tol=None, x_rtol=None,
line_search='armijo', callback=None, **kw)
```

Find a root of a function, using Broyden’s first Jacobian approximation.
This method is also known as “Broyden’s good method”.

**Parameters**

- **F**: function(x) -> f
  Function whose root to find; should take and return an array-like object.

- **xin**: array_like
  Initial guess for the solution

- **alpha**: float, optional
  Initial guess for the Jacobian is \((-1/\alpha)\).

- **reduction_method**: str or tuple, optional
  Method used in ensuring that the rank of the Broyden matrix stays low. Can either be a string giving the name of the method, or a tuple of the form (method, param1, param2, ...) that gives the name of the method and values for additional parameters.

  Methods available:
  - **restart**: drop all matrix columns. Has no extra parameters.
  - **simple**: drop oldest matrix column. Has no extra parameters.
  - **svd**: keep only the most significant SVD components. Takes an extra parameter, `to_retain`, which determines the number of SVD components to retain when rank reduction is done. Default is `max_rank - 2`.

- **max_rank**: int, optional
  Maximum rank for the Broyden matrix. Default is infinity (ie., no rank reduction).

- **iter**: int, optional
  Number of iterations to make. If omitted (default), make as many as required to meet tolerances.

- **verbose**: bool, optional
  Print status to stdout on every iteration.

- **maxiter**: int, optional
  Maximum number of iterations to make. If more are needed to meet convergence, `NoConvergence` is raised.

- **f_tol**: float, optional
  Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.

- **f_rtol**: float, optional
  Relative tolerance for the residual. If omitted, not used.

- **x_tol**: float, optional
  Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.

- **x_rtol**: float, optional
  Relative minimum step size. If omitted, not used.

- **tol_norm**: function(vector) -> scalar, optional
  Norm to use in convergence check. Default is the maximum norm.

- **line_search**: {None, ‘armijo’ (default), ‘wolfe’}, optional
  Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to ‘armijo’.

- **callback**: function, optional
  Optional callback function. It is called on every iteration as `callback(x, f)` where `x` is the current solution and `f` the corresponding residual.

**Returns**

- **sol**: ndarray
  An array (of similar array type as `xin`) containing the final solution.

**Raises**

- `NoConvergence`
  When a solution was not found.
Notes

This algorithm implements the inverse Jacobian Quasi-Newton update

\[ H_+ = H + (dx - H df)dx^\dagger H/(dx^\dagger H df) \]

which corresponds to Broyden’s first Jacobian update

\[ J_+ = J + (df - J dx)dx^\dagger/(dx^\dagger dx) \]

References

Find a root of a function, using Broyden’s second Jacobian approximation.

This method is also known as “Broyden’s bad method”.

Parameters

- **F**: function(x) -> f
  Function whose root to find; should take and return an array-like object.
- **xin**: array_like
  Initial guess for the solution
- **alpha**: float, optional
  Initial guess for the Jacobian is (-1/alpha).
- **reduction_method**: str or tuple, optional
  Method used in ensuring that the rank of the Broyden matrix stays low. Can either be a string giving the name of the method, or a tuple of the form (method, param1, param2, ...) that gives the name of the method and values for additional parameters.
  Methods available:
  • restart: drop all matrix columns. Has no extra parameters.
  • simple: drop oldest matrix column. Has no extra parameters.
  • svd: keep only the most significant SVD components. Takes an extra parameter, to_retain, which determines the number of SVD components to retain when rank reduction is done. Default is max_rank - 2.
- **max_rank**: int, optional
  Maximum rank for the Broyden matrix. Default is infinity (ie., no rank reduction).
- **iter**: int, optional
  Number of iterations to make. If omitted (default), make as many as required to meet tolerances.
- **verbose**: bool, optional
  Print status to stdout on every iteration.
- **maxiter**: int, optional
  Maximum number of iterations to make. If more are needed to meet convergence, NoConvergence is raised.
- **f_tol**: float, optional
  Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.
- **f_rtol**: float, optional
  Relative tolerance for the residual. If omitted, not used.
- **x_tol**: float, optional
  Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.
SciPy Reference Guide, Release 1.0.0

**x_rtol**: float, optional
Relative minimum step size. If omitted, not used.

**tol_norm**: function(vector) -> scalar, optional
Norm to use in convergence check. Default is the maximum norm.

**line_search**: [None, ‘armijo’ (default), ‘wolfe’], optional
Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to ‘armijo’.

**callback**: function, optional
Optional callback function. It is called on every iteration as `callback(x, f)` where `x` is the current solution and `f` the corresponding residual.

**Returns**

* **sol**: ndarray
An array (of similar array type as `x0`) containing the final solution.

**Raises**

* **NoConvergence**
When a solution was not found.

**Notes**

This algorithm implements the inverse Jacobian Quasi-Newton update

\[
H_+ = H + (dx - H df^\top) df^\top / (df^\top df)
\]

corresponding to Broyden’s second method.

**References**

[R193]
The `root` function supports the following methods:

**root(method=’hybr’)**

scipy.optimize.root (fun, x0, args=(), method=’hybr’, jac=None, tol=None, callback=None, options={'col_deriv': 0, 'diag': None, 'factor': 100, 'eps': None, 'band': None, 'func': None, 'maxfev': 0, 'xtol': 1.49012e-08})

Find the roots of a multivariate function using MINPACK’s hybrd and hybrj routines (modified Powell method).

**See also:**

For documentation for the rest of the parameters, see `scipy.optimize.root`
A parameter determining the initial step bound \((\text{factor} \times ||\text{diag} \times x||)\).
Should be in the interval \((0.1, 100)\).

**Parameters**

- **diag**: sequence
  
  N positive entries that serve as a scale factors for the variables.

### root(method='lm')

```python
scipy.optimize.root (fun, x0, args=(), method='lm', jac=None, tol=None, callback=None, options={'col_deriv': 0, 'diag': None, 'factor': 100, 'gtol': 0.0, 'eps': 0.0, 'func': None, 'maxiter': 0, 'xtol': 1.49012e-08, 'ftol': 1.49012e-08})
```

Solve for least squares with Levenberg-Marquardt

### See also:

For documentation for the rest of the parameters, see `scipy.optimize.root`

### Options

- **col_deriv**: bool
  
  non-zero to specify that the Jacobian function computes derivatives down the columns
  (faster, because there is no transpose operation).

- **ftol**: float
  
  Relative error desired in the sum of squares.

- **xtol**: float
  
  Relative error desired in the approximate solution.

- **gtol**: float
  
  Orthogonality desired between the function vector and the columns of the Jacobian.

- **maxiter**: int
  
  The maximum number of calls to the function. If zero, then \(100^*(N+1)\) is the maximum
  where \(N\) is the number of elements in \(x_0\).

- **epsfcn**: float
  
  A suitable step length for the forward-difference approximation of the Jacobian (for
  \(Df\text{un}=None\)). If epsfcn is less than the machine precision, it is assumed that the relative
  errors in the functions are of the order of the machine precision.

- **factor**: float
  
  A parameter determining the initial step bound \((\text{factor} \times ||\text{diag} \times x||)\).
  Should be in interval \((0.1, 100)\).

- **diag**: sequence
  
  N positive entries that serve as a scale factors for the variables.

### root(method='broyden1')

```python
scipy.optimize.root (fun, x0, args=(), method='broyden1', tol=None, callback=None, options={})
```

### See also:

For documentation for the rest of the parameters, see `scipy.optimize.root`

### Options

- **nit**: int, optional
  
  Number of iterations to make. If omitted (default), make as many as required to meet
tolerances.

- **disp**: bool, optional
  
  Print status to stdout on every iteration.

- **maxiter**: int, optional
  
  Maximum number of iterations to make. If more are needed to meet convergence,
  NoConvergence is raised.

- **ftol**: float, optional
  
  Relative tolerance for the residual. If omitted, not used.
fatol : float, optional
    Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.
xtol : float, optional
    Relative minimum step size. If omitted, not used.
xatol : float, optional
    Absolute minimum step size, as determined from the Jacobian approximation. If the
    step size is smaller than this, optimization is terminated as successful. If omitted, not
    used.
tol_norm : function(vector) -> scalar, optional
    Norm to use in convergence check. Default is the maximum norm.
line_search : {None, ‘armijo’ (default), ‘wolfe’}, optional
    Which type of a line search to use to determine the step size in the direction given by
    the Jacobian approximation. Defaults to ‘armijo’.
jac_options : dict, optional
    Options for the respective Jacobian approximation.

    alpha [float, optional] Initial guess for the Jacobian is (-1/alpha).

    reduction_method
    [str or tuple, optional] Method used in ensuring that
    the rank of the Broyden matrix stays low. Can either
    be a string giving the name of the method, or a tuple
    of the form (method, param1, param2, ...) that gives the name of the method and values for
    additional parameters.

    Methods available:

    • restart: drop all matrix columns. Has no
    extra parameters.

    • simple: drop oldest matrix column. Has no
    extra parameters.

    • svd: keep only the most significant SVD
    components.

    Extra parameters:

    --to_retain: number of SVD components

    retain when
    rank reduc- tion is
    done. De-
    fault is
    max_rank
    - 2.

    max_rank [int, optional] Maximum rank for the Broyden matrix.
    Default is infinity (ie., no rank reduction).
**root(method='broyden2')**

```python
scipy.optimize.root (fun, x0, args=(), method='broyden2', tol=None, callback=None, options={})
```

See also:
For documentation for the rest of the parameters, see `scipy.optimize.root`

**Options**

- **nit**: int, optional
  
  Number of iterations to make. If omitted (default), make as many as required to meet tolerances.

- **disp**: bool, optional
  
  Print status to stdout on every iteration.

- **maxiter**: int, optional
  
  Maximum number of iterations to make. If more are needed to meet convergence, `NoConvergence` is raised.

- **ftol**: float, optional
  
  Relative tolerance for the residual. If omitted, not used.

- **fatol**: float, optional
  
  Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.

- **xtol**: float, optional
  
  Relative minimum step size. If omitted, not used.

- **xatol**: float, optional
  
  Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.

- **tol_norm**: function(vector) -> scalar, optional
  
  Norm to use in convergence check. Default is the maximum norm.

- **line_search**: {None, 'armijo' (default), 'wolfe'}, optional
  
  Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to ‘armijo’.

- **jac_options**: dict, optional
  
  Options for the respective Jacobian approximation.

- **alpha**: [float, optional]
  
  Initial guess for the Jacobian is (-1/alpha).

- **reduction_method**: [str or tuple, optional]
  
  Method used in ensuring that the rank of the Broyden matrix stays low. Can either be a string giving the name of the method, or a tuple of the form `(method, param1, param2, ...)` that gives the name of the method and values for additional parameters.

**Methods available:**

- **restart**: drop all matrix columns. Has no extra parameters.

- **simple**: drop oldest matrix column. Has no extra parameters.

- **svd**: keep only the most significant SVD components.

  Extra parameters:
to_retain is the number of SVD components to retain when rank reduction is done. Default is $max_rank - 2$.

$max_rank$ is the maximum rank for the Broyden matrix. Default is infinity (ie., no rank reduction).

**root**

```python
root = scipy.optimize.root(fun, x0, args=(), method='anderson', tol=None, callback=None, options={})
```

**Options**

- **nit** : int, optional
  Number of iterations to make. If omitted (default), make as many as required to meet tolerances.

- **disp** : bool, optional
  Print status to stdout on every iteration.

- **maxiter** : int, optional
  Maximum number of iterations to make. If more are needed to meet convergence, `NoConvergence` is raised.

- **ftol** : float, optional
  Relative tolerance for the residual. If omitted, not used.

- **fatol** : float, optional
  Absolute tolerance (in max-norm) for the residual. If omitted, default is $6e-6$.

- **xtol** : float, optional
  Relative minimum step size. If omitted, not used.

- **xatol** : float, optional
  Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.

- **tol_norm** : function(vector) -> scalar, optional
  Norm to use in convergence check. Default is the maximum norm.

- **line_search** : {None, ‘armijo’ (default), ‘wolfe’}, optional
  Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to ‘armijo’.

- **jac_options** : dict, optional
  Options for the respective Jacobian approximation.

- **alpha** : float, optional
  Initial guess for the Jacobian is $(-1/alpha)$.

- **M** : float, optional
  Number of previous vectors to retain. Defaults to 5.

Options

nit : int, optional
      Number of iterations to make. If omitted (default), make as many as re-
      quired to meet tolerances.

disp : bool, optional
      Print status to stdout on every iteration.

maxiter : int, optional
      Maximum number of iterations to make. If more are needed to meet con-
      vergence, NoConvergence is raised.

ftol : float, optional
      Relative tolerance for the residual. If omitted, not used.

fatol : float, optional
      Absolute tolerance (in max-norm) for the residual. If omitted, default is
      6e-6.

xtol : float, optional
      Relative minimum step size. If omitted, not used.

xatol : float, optional
      Absolute minimum step size, as determined from the Jacobian approxima-
      tion. If the step size is smaller than this, optimization is terminated as suc-
      cessful. If omitted, not used.

tol_norm : function(vector) -> scalar, optional
      Norm to use in convergence check. Default is the maximum norm.

line_search : {None, ‘armijo’ (default), ‘wolfe’}, optional
      Which type of a line search to use to determine the step size in the direction
      given by the Jacobian approximation. Defaults to ‘armijo’.

jac_options : dict, optional
      Options for the respective Jacobian approximation.
**alpha**

Initial Jacobian approximation is \((-1/\text{alpha})\).

**alphamax**

The entries of the diagonal Jacobian are kept in the range \([\text{alpha}, \text{alphamax}]\).

**root** (method='krylov')

`scipy.optimize.root` (fun, x0, args=(), method='krylov', tol=None, callback=None, options={})

**See also:**

For documentation for the rest of the parameters, see `scipy.optimize.root`

**Options**

- **nit** : int, optional
  Number of iterations to make. If omitted (default), make as many as required to meet tolerances.

- **disp** : bool, optional
  Print status to stdout on every iteration.

- **maxiter** : int, optional
  Maximum number of iterations to make. If more are needed to meet convergence, `NoConvergence` is raised.

- **ftol** : float, optional
  Relative tolerance for the residual. If omitted, not used.

- **fatol** : float, optional
  Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.

- **xtol** : float, optional
  Relative minimum step size. If omitted, not used.

- **xatol** : float, optional
  Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.

- **tol_norm** : function(vector) -> scalar, optional
  Norm to use in convergence check. Default is the maximum norm.

- **line_search** : {None, ‘armijo’ (default), ‘wolfe’}, optional
  Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to ‘armijo’.

- **jac_options** : dict, optional
  Options for the respective Jacobian approximation.

- **rdiff** : [float, optional]
  Relative step size to use in numerical differentiation.

  Krylov method to use to approximate the Jacobian. Can be a string, or a function implementing the same interface as the iterative solvers in `scipy.sparse.linalg`. The default is `scipy.sparse.linalg.lgmres`.

- **inner_M** : [LinearOperator or InverseJacobian]
  Preconditioner for the inner Krylov iteration. Note that you can use also inverse Jacobians as (adaptive) preconditioners. For example,

```python
>>> jac = BroydenFirst()
>>> kjac = KrylovJacobian(inner_M=jac.inverse).
```

If the preconditioner has a method named `update`, it will be called as `update(x, f)` after each nonlinear step, with `x` giving the current point, and `f` the current function value.
inner_tol, inner_maxiter, ...
Parameters to pass on to the “inner” Krylov solver. See scipy.sparse.linalg.gmres for details.

outer_k
[int, 'optional'] Size of the subspace kept across LGMRES nonlinear iterations. See scipy.sparse.linalg.lgmres for details.

root(method='df-sane')
Solve nonlinear equation with the DF-SANE method

See also:
For documentation for the rest of the parameters, see scipy.optimize.root

Options

ftol : float, optional
Relative norm tolerance.
fatol : float, optional
Absolute norm tolerance. Algorithm terminates when ||func(x)|| < fatol + ftol ||func(x_0)||.
fnorm : callable, optional
Norm to use in the convergence check. If None, 2-norm is used.
maxfev : int, optional
Maximum number of function evaluations.
disp : bool, optional
Whether to print convergence process to stdout.
eta_strategy : callable, optional
Choice of the eta_k parameter, which gives slack for growth of ||F||**2. Called as eta_k = eta_strategy(k, x, F) with k the iteration number, x the current iterate and F the current residual. Should satisfy eta_k > 0 and sum(eta, k=0..inf) < inf. Default: ||F||**2 / (1 + k)**2.
sigma_eps : float, optional
The spectral coefficient is constrained to sigma_eps < sigma < 1/sigma_eps. Default: 1e-10
sigma_0 : float, optional
Initial spectral coefficient. Default: 1.0
M : int, optional
Number of iterates to include in the nonmonotonic line search. Default: 10

line_search : {‘cruz’, ‘cheng’}
Type of line search to employ. ‘cruz’ is the original one defined in [Martinez & Raydan. Math. Comp. 75, 1429 (2006)], ‘cheng’ is a modified search defined in [Cheng & Li. IMA J. Numer. Anal. 29, 814 (2009)]. Default: ‘cruz’

Large-scale nonlinear solvers:

Continued on next page
newton_krylov(F, xin[, iter, rdiff, method, ...])

Find a root of a function, using Krylov approximation for inverse Jacobian.

anderson(F, xin[, iter, alpha, w0, M, ...])

Find a root of a function, using (extended) Anderson mixing.

**scipy.optimize.newton_krylov**

```python
scipy.optimize.newton_krylov(F, xin, iter=None, rdiff=None, method='lgmres', inner_maxiter=20, inner_M=None, outer_k=10, verbose=False, maxiter=None, f_tol=None, f_rtol=None, x_tol=None, x_rtol=None, tol_norm=None, line_search='armijo', call=*
```

Find a root of a function, using Krylov approximation for inverse Jacobian.

This method is suitable for solving large-scale problems.

**Parameters**

- **F**: function(x) -> f
  Function whose root to find; should take and return an array-like object.
- **xin**: array_like
  Initial guess for the solution
- **rdiff**: float, optional
  Relative step size to use in numerical differentiation.
- **method**: {'lgmres', 'gmres', 'bicgstab', 'cgs', 'minres'} or function
  Krylov method to use to approximate the Jacobian. Can be a string, or a function implementing the same interface as the iterative solvers in `scipy.sparse.linalg`.
  The default is `scipy.sparse.linalg.lgmres`.
- **inner_M**: LinearOperator or InverseJacobian
  Preconditioner for the inner Krylov iteration. Note that you can use also inverse Jacobians as (adaptive) preconditioners. For example,

  ```python
  >>> from scipy.optimize.nonlin import BroydenFirst,
  >>> KrylovJacobian
  >>> from scipy.optimize.nonlin import InverseJacobian
  >>> jac = BroydenFirst()
  >>> kjac = KrylovJacobian(inner_M=InverseJacobian(jac))
  ```

  If the preconditioner has a method named 'update', it will be called as update(x, f) after each nonlinear step, with x giving the current point, and f the current function value.
- **inner_tol**, **inner_maxiter**, ...
  Parameters to pass on to the “inner” Krylov solver. See `scipy.sparse.linalg.gmres` for details.
- **outer_k**: int, optional
  Size of the subspace kept across LGMRES nonlinear iterations. See `scipy.sparse.linalg.lgmres` for details.
- **iter**: int, optional
  Number of iterations to make. If omitted (default), make as many as required to meet tolerances.
- **verbose**: bool, optional
  Print status to stdout on every iteration.
- **maxiter**: int, optional
  Maximum number of iterations to make. If more are needed to meet convergence, `NoConvergence` is raised.
- **f_tol**: float, optional

1056 Chapter 5. API Reference
Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.

**f_rtol** : float, optional
Relative tolerance for the residual. If omitted, not used.

**x_tol** : float, optional
Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.

**x_rtol** : float, optional
Relative minimum step size. If omitted, not used.

**tol_norm** : function(vector) -> scalar, optional
Norm to use in convergence check. Default is the maximum norm.

**line_search** : {None, ‘armijo’ (default), ‘wolfe’}, optional
Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to ‘armijo’.

**callback** : function, optional
Optional callback function. It is called on every iteration as `callback(x, f)` where `x` is the current solution and `f` the corresponding residual.

**Returns**

**sol** : ndarray
An array (of similar array type as `x0`) containing the final solution.

**Raises**

**NoConvergence**
When a solution was not found.

*scipy.sparse.linalg.gmres, scipy.sparse.linalg.lgmres*

Notes

This function implements a Newton-Krylov solver. The basic idea is to compute the inverse of the Jacobian with an iterative Krylov method. These methods require only evaluating the Jacobian-vector products, which are conveniently approximated by a finite difference:

\[ Jv \approx \frac{(f(x + \omega * v/|v|) - f(x))/\omega}{v} \]

Due to the use of iterative matrix inverses, these methods can deal with large nonlinear problems.

SciPy’s *scipy.sparse.linalg* module offers a selection of Krylov solvers to choose from. The default here is *lgmres*, which is a variant of restarted GMRES iteration that reuses some of the information obtained in the previous Newton steps to invert Jacobians in subsequent steps.

For a review on Newton-Krylov methods, see for example [R219], and for the LGMRES sparse inverse method, see [R220].

*scipy.optimize.anderson(F, xin, iter=None, alpha=None, w0=0.01, M=5, verbose=False, maxiter=None, f_tol=None, f_rtol=None, x_tol=None, x_rtol=None, tol_norm=None, line_search='armijo', callback=None, **kw)*

Find a root of a function, using (extended) Anderson mixing.

The Jacobian is formed by for a ‘best’ solution in the space spanned by last `M` vectors. As a result, only a MxM matrix inversions and MxN multiplications are required. [Ey]

**Parameters**

**F** : function(x) -> f
Function whose root to find; should take and return an array-like object.

**xin** : array_like
Initial guess for the solution

**alpha** : float, optional

Initial guess for the Jacobian is \((-1/alpha)\).

**M** : float, optional

Number of previous vectors to retain. Defaults to 5.

**w0** : float, optional

Regularization parameter for numerical stability. Compared to unity, good values of the order of 0.01.

**iter** : int, optional

Number of iterations to make. If omitted (default), make as many as required to meet tolerances.

**verbose** : bool, optional

Print status to stdout on every iteration.

**maxiter** : int, optional

Maximum number of iterations to make. If more are needed to meet convergence, **NoConvergence** is raised.

**f_tol** : float, optional

Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.

**f_rtol** : float, optional

Relative tolerance for the residual. If omitted, not used.

**x_tol** : float, optional

Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.

**x_rtol** : float, optional

Relative minimum step size. If omitted, not used.

**tol_norm** : function(vector) -> scalar, optional

Norm to use in convergence check. Default is the maximum norm.

**line_search** : {None, ‘armijo’ (default), ‘wolfe’}, optional

Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to ‘armijo’.

**callback** : function, optional

Optional callback function. It is called on every iteration as callback(x, f) where x is the current solution and f the corresponding residual.

**Returns**

**sol** : ndarray
An array (of similar array type as x0) containing the final solution.

**Raises**

**NoConvergence**

When a solution was not found.

Find a root of a function, using diagonal Broyden Jacobian approximation.
SciPy Reference Guide, Release 1.0.0

**scipy.optimize.excitingmixing** *(F, xin, iter=None, alpha=None, alphamax=1.0, verbose=False, maxiter=None, f_tol=None, f_rtol=None, x_tol=None, x_rtol=None, tol_norm=None, line_search='armijo', callback=None, **kw)*

Find a root of a function, using a tuned diagonal Jacobian approximation.

The Jacobian matrix is diagonal and is tuned on each iteration.

**Warning:** This algorithm may be useful for specific problems, but whether it will work may depend strongly on the problem.

**Parameters**

- **F**: function(x) -> f
  - Function whose root to find; should take and return an array-like object.

- **xin**: array_like
  - Initial guess for the solution

- **alpha**: float, optional
  - Initial Jacobian approximation is (-1/alpha).

- **alphamax**: float, optional
  - The entries of the diagonal Jacobian are kept in the range [alpha, alphamax].

- **iter**: int, optional
  - Number of iterations to make. If omitted (default), make as many as required to meet tolerances.

- **verbose**: bool, optional
  - Print status to stdout on every iteration.

- **maxiter**: int, optional
  - Maximum number of iterations to make. If more are needed to meet convergence, **NoConvergence** is raised.

- **f_tol**: float, optional
  - Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.

- **f_rtol**: float, optional
  - Relative tolerance for the residual. If omitted, not used.

- **x_tol**: float, optional
  - Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.

- **x_rtol**: float, optional
  - Relative minimum step size. If omitted, not used.

- **tol_norm**: function(vector) -> scalar, optional
  - Norm to use in convergence check. Default is the maximum norm.

- **line_search**: {None, ‘armijo’ (default), ‘wolfe’}, optional
  - Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to ‘armijo’.

- **callback**: function, optional
  - Optional callback function. It is called on every iteration as callback(x, f) where x is the current solution and f the corresponding residual.

**Returns**

- **sol**: ndarray
  - An array (of similar array type as x0) containing the final solution.

**Raises**

- **NoConvergence**
  - When a solution was not found.
Find a root of a function, using a scalar Jacobian approximation.

**Warning:** This algorithm may be useful for specific problems, but whether it will work may depend strongly on the problem.

### Parameters
- **F**: function(x) -> f
  Function whose root to find; should take and return an array-like object.
- **xin**: array_like
  Initial guess for the solution
- **alpha**: float, optional
  The Jacobian approximation is (-1/alpha).
- **iter**: int, optional
  Number of iterations to make. If omitted (default), make as many as required to meet tolerances.
- **verbose**: bool, optional
  Print status to stdout on every iteration.
- **maxiter**: int, optional
  Maximum number of iterations to make. If more are needed to meet convergence, NoConvergence is raised.
- **f_tol**: float, optional
  Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.
- **f_rtol**: float, optional
  Relative tolerance for the residual. If omitted, not used.
- **x_tol**: float, optional
  Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.
- **x_rtol**: float, optional
  Relative minimum step size. If omitted, not used.
- **tol_norm**: function(vector) -> scalar, optional
  Norm to use in convergence check. Default is the maximum norm.
- **line_search**: {None, 'armijo' (default), 'wolfe'}, optional
  Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to ‘armijo’.
- **callback**: function, optional
  Optional callback function. It is called on every iteration as callback(x, f) where x is the current solution and f the corresponding residual.

### Returns
- **sol**: ndarray
  An array (of similar array type as x0) containing the final solution.

### Raises
- **NoConvergence**
  When a solution was not found.

Find a root of a function, using a diagonal Broyden Jacobian approximation.

The Jacobian approximation is derived from previous iterations, by retaining only the diagonal of Broyden matrices.
Warning: This algorithm may be useful for specific problems, but whether it will work may depend strongly on the problem.

**Parameters**

- **F**: function(x) -> f
  Function whose root to find; should take and return an array-like object.
- **xin**: array_like
  Initial guess for the solution
- **alpha**: float, optional
  Initial guess for the Jacobian is (-1/alpha).
- **iter**: int, optional
  Number of iterations to make. If omitted (default), make as many as required to meet tolerances.
- **verbose**: bool, optional
  Print status to stdout on every iteration.
- **maxiter**: int, optional
  Maximum number of iterations to make. If more are needed to meet convergence, **NoConvergence** is raised.
- **f_tol**: float, optional
  Absolute tolerance (in max-norm) for the residual. If omitted, default is 6e-6.
- **f_rtol**: float, optional
  Relative tolerance for the residual. If omitted, not used.
- **x_tol**: float, optional
  Absolute minimum step size, as determined from the Jacobian approximation. If the step size is smaller than this, optimization is terminated as successful. If omitted, not used.
- **x_rtol**: float, optional
  Relative minimum step size. If omitted, not used.
- **tol_norm**: function(vector) -> scalar, optional
  Norm to use in convergence check. Default is the maximum norm.
- **line_search**: {None, ‘armijo’ (default), ‘wolfe’}, optional
  Which type of a line search to use to determine the step size in the direction given by the Jacobian approximation. Defaults to ‘armijo’.
- **callback**: function, optional
  Optional callback function. It is called on every iteration as callback(x, f) where x is the current solution and f the corresponding residual.

**Returns**

- **sol**: ndarray
  An array (of similar array type as x0) containing the final solution.

**Raises**

- **NoConvergence**
  When a solution was not found.

5.18.4 Linear Programming

General linear programming solver:

```
linprog(c[, A_ub, b_ub, A_eq, b_eq, bounds, ...])
```

Minimize a linear objective function subject to linear equality and inequality constraints.
scipy.optimize.linprog(c, A_ub=None, b_ub=None, A_eq=None, b_eq=None, bounds=None, method='simplex', callback=None, options=None)

Minimize a linear objective function subject to linear equality and inequality constraints.

Linear Programming is intended to solve the following problem form:

| Minimize:   | $c^T \times x$ |
| Subject to: | $A_{ub} \times x \leq b_{ub}$ |
|            | $A_{eq} \times x = b_{eq}$ |

**Parameters**

- **c**: array_like
  Coefficients of the linear objective function to be minimized.
- **A_ub**: array_like, optional
  2-D array which, when matrix-multiplied by $x$, gives the values of the upper-bound inequality constraints at $x$.
- **b_ub**: array_like, optional
  1-D array of values representing the upper-bound of each inequality constraint (row) in $A_{ub}$.
- **A_eq**: array_like, optional
  2-D array which, when matrix-multiplied by $x$, gives the values of the equality constraints at $x$.
- **b_eq**: array_like, optional
  1-D array of values representing the RHS of each equality constraint (row) in $A_{eq}$.
- **bounds**: sequence, optional
  $(\text{min, max})$ pairs for each element in $x$, defining the bounds on that parameter. Use None for one of min or max when there is no bound in that direction. By default bounds are (0, None) (non-negative) If a sequence containing a single tuple is provided, then min and max will be applied to all variables in the problem.
- **method**: str, optional
  Type of solver. ‘simplex’ and ‘interior-point’ are supported.
- **callback**: callable, optional (simplex only)
  If a callback function is provide, it will be called within each iteration of the simplex algorithm. The callback must have the signature callback($xk, **kwargs$) where $xk$ is the current solution vector and $kwargs$ is a dictionary containing the following:

  "tableau" : The current Simplex algorithm tableau
  "nit" : The current iteration.
  "pivot" : The pivot (row, column) used for the next iteration.
  "phase" : Whether the algorithm is in Phase 1 or Phase 2.
  "basis" : The indices of the columns of the basic variables.

- **options**: dict, optional
  A dictionary of solver options. All methods accept the following generic options:

  - **maxiter** [int] Maximum number of iterations to perform.
  - **disp** [bool] Set to True to print convergence messages.

  For method-specific options, see show_options('linprog').
Returns

A \texttt{scipy.optimize.OptimizeResult} consisting of the following fields:

- \texttt{x} [ndarray] The independent variable vector which optimizes the linear programming problem.
- \texttt{fun} [float] Value of the objective function.
- \texttt{slack} [ndarray] The values of the slack variables. Each slack variable corresponds to an inequality constraint. If the slack is zero, then the corresponding constraint is active.
- \texttt{success} [bool] Returns True if the algorithm succeeded in finding an optimal solution.
- \texttt{status} [int] An integer representing the exit status of the optimization:
  - 0: Optimization terminated successfully
  - 1: Iteration limit reached
  - 2: Problem appears to be infeasible
  - 3: Problem appears to be unbounded
- \texttt{nit} [int] The number of iterations performed.
- \texttt{message} [str] A string descriptor of the exit status of the optimization.

See also:

\texttt{show_options}

Additional options accepted by the solvers

Notes

This section describes the available solvers that can be selected by the ‘method’ parameter. The default method is \texttt{Simplex}. \texttt{Interior point} is also available.

Method \texttt{simplex} uses the simplex algorithm (as it relates to linear programming, NOT the Nelder-Mead simplex) \cite{R201}, \cite{R202}. This algorithm should be reasonably reliable and fast for small problems.

New in version 0.15.0.

Method \texttt{interior-point} uses the primal-dual path following algorithm as outlined in \cite{R204}. This algorithm is intended to provide a faster and more reliable alternative to \texttt{simplex}, especially for large, sparse problems. Note, however, that the solution returned may be slightly less accurate than that of the simplex method and may not correspond with a vertex of the polytope defined by the constraints.

References

\cite{R201}, \cite{R202}, \cite{R203}, \cite{R204}, \cite{R205}, \cite{R206}, \cite{R207}, \cite{R208}, \cite{R209}.

Examples

Consider the following problem:

Minimize: \( f = -1 \times x[0] + 4 \times x[1] \)

Subject to: \( -3 \times x[0] + 1 \times x[1] \leq 6 \)
\( 1 \times x[0] + 2 \times x[1] \leq 4 \)
\( x[1] \geq -3 \)

where: \(-\infty \leq x[0] \leq \infty\)

This problem deviates from the standard linear programming problem. In standard form, linear programming problems assume the variables \( x \) are non-negative. Since the variables don’t have standard bounds where \( 0 \leq x \leq \infty \), the bounds of the variables must be explicitly set.

There are two upper-bound constraints, which can be expressed as

\( \text{dot}(A_{\text{ub}}, x) \leq b_{\text{ub}} \)

The input for this problem is as follows:

```python
>>> c = [-1, 4]
>>> A = [[-3, 1], [1, 2]]
>>> b = [6, 4]
>>> x0_bounds = (None, None)
>>> x1_bounds = (-3, None)
>>> from scipy.optimize import linprog
>>> res = linprog(c, A_ub=A, b_ub=b, bounds=(x0_bounds, x1_bounds),
...                options={'disp': True})
Optimization terminated successfully.
Current function value: -22.000000
Iterations: 1
>>> print(res)
   fun: -22.0
   message: 'Optimization terminated successfully.'
   nit: 1
   slack: array([ 39.,  0.])
   status: 0
   success: True
   x: array([ 10.,  -3.])
```

Note the actual objective value is 11.428571. In this case we minimized the negative of the objective function.

The `linprog` function supports the following methods:

```
linprog(method='simplex')
```

The following linear programming problem via a two-phase simplex algorithm.

```
minimize: c^T * x
subject to: A_ub * x <= b_ub
            A_eq * x == b_eq
```

**Parameters**

- `c`: array_like
  Coefficients of the linear objective function to be minimized.
- `A_ub`: array_like
  2-D array which, when matrix-multiplied by `x`, gives the values of the upper-bound inequality constraints at `x`.
- `b_ub`: array_like
  1-D array of values representing the upper-bound of each inequality constraint (row) in `A_ub`.
- `A_eq`: array_like
  2-D array which, when matrix-multiplied by `x`, gives the values of the equality constraints at `x`.
- `b_eq`: array_like
  1-D array of values representing the RHS of each equality constraint (row) in `A_eq`.
- `bounds`: array_like
  The bounds for each independent variable in the solution, which can take one of three forms:
None : The default bounds, all variables are non-negative. (lb, ub) : If a 2-element sequence is provided, the same lower bound (lb) and upper bound (ub) will be applied to all variables.

\[(lb_0, ub_0), (lb_1, ub_1), \ldots\]  
[If an n x 2 sequence is provided, each variable \(x_i\) will be bounded by \(lb[i]\) and \(ub[i]\).]  
Infinite bounds are specified using -np.inf (negative) or np.inf (positive).

**callback** : callable
If a callback function is provide, it will be called within each iteration of the simplex algorithm. The callback must have the signature `callback(xk, **kwargs)` where `xk` is the current solution vector and kwargs is a dictionary containing the following:

- **"tableau"** : The current Simplex algorithm tableau
- **"nit"** : The current iteration.
- **"pivot"** : The pivot (row, column) used for the next iteration.
- **"phase"** : Whether the algorithm is in Phase 1 or Phase 2.
- **"bv"** : A structured array containing a string representation of each basic variable and its current value.

**Returns**
A `scipy.optimize.OptimizeResult` consisting of the following fields:

- **x** : [ndarray] The independent variable vector which optimizes the linear programming problem.
- **fun** : [float] Value of the objective function.
- **slack** : [ndarray] The values of the slack variables. Each slack variable corresponds to an inequality constraint. If the slack is zero, then the corresponding constraint is active.
- **success** : [bool] Returns True if the algorithm succeeded in finding an optimal solution.
- **status** : [int] An integer representing the exit status of the optimization:
  - 0 : Optimization terminated successfully
  - 1 : Iteration limit reached
  - 2 : Problem appears to be infeasible
  - 3 : Problem appears to be unbounded
- **nit** : [int] The number of iterations performed.
- **message** : [str] A string descriptor of the exit status of the optimization.

See also:
For documentation for the rest of the parameters, see `scipy.optimize.linprog`

**Options**

- **maxiter** : int  
The maximum number of iterations to perform.
- **disp** : bool  
If True, print exit status message to sys.stdout
- **tol** : float  
The tolerance which determines when a solution is “close enough” to zero in Phase 1 to be considered a basic feasible solution or close enough to positive to serve as an optimal solution.
- **bland** : bool
If True, use Bland’s anti-cycling rule [3] to choose pivots to prevent cycling. If False, choose pivots which should lead to a converged solution more quickly. The latter method is subject to cycling (non-convergence) in rare instances.

Examples
Consider the following problem:
Minimize: \( f = -1 \times x[0] + 4 \times x[1] \)
Subject to: \( -3 \times x[0] + 1 \times x[1] \leq 6 \)
\( 1 \times x[0] + 2 \times x[1] \leq 4 \)
\( x[1] \geq -3 \)
where: \(-\infty \leq x[0] \leq \infty\)
This problem deviates from the standard linear programming problem. In standard form, linear programming problems assume the variables \( x \) are non-negative. Since the variables don’t have standard bounds where \( 0 \leq x \leq \infty \), the bounds of the variables must be explicitly set.

There are two upper-bound constraints, which can be expressed as
\( \text{dot}(A_{ub}, x) \leq b_{ub} \)

The input for this problem is as follows:

```python
>>> from scipy.optimize import linprog
>>> c = [-1, 4]
>>> A = [[-3, 1], [1, 2]]
>>> b = [6, 4]
>>> x0_bnds = (None, None)
>>> x1_bnds = (-3, None)
>>> res = linprog(c, A, b, bounds=(x0_bnds, x1_bnds))
>>> print(res)
fun: -22.0
message: 'Optimization terminated successfully.'
nit: 1
slack: array([ 39.,  0.])
status: 0
success: True
x: array([ 10., -3.])
```

linprog(method='interior-point')

scipy.optimize.linprog(c, A_ub=None, b_ub=None, A_eq=None, b_eq=None, bounds=None, method='interior-point', callback=None, options={'disp': False, 'sym_pos': True, 'alpha0': 0.99995, 'cholesky': None, 'tol': 1e-08, 'rr': True, 'ip': False, 'perm_code': 'MMD_AT_PLUS_A', 'pc': True, 'beta': 0.1, 'lstsq': False, 'sparse': False, 'maxiter': 1000, 'presolve': True, '_sparse_presolve': False})

Minimize a linear objective function subject to linear equality constraints, linear inequality constraints, and simple bounds using the interior point method of [R901]. Linear programming is intended to solve problems of the following form:
Minimize: $c^T \cdot x$
Subject to: $A_{ub} \cdot x \leq b_{ub}$
$A_{eq} \cdot x = b_{eq}$
$bounds[i][0] < x_i < bounds[i][1]$

**Parameters**

- **c**: array_like
  Coefficients of the linear objective function to be minimized.
- **A_ub**: array_like, optional
  2-D array which, when matrix-multiplied by $x$, gives the values of the upper-bound inequality constraints at $x$.
- **b_ub**: array_like, optional
  1-D array of values representing the upper-bound of each inequality constraint (row) in $A_{ub}$.
- **A_eq**: array_like, optional
  2-D array which, when matrix-multiplied by $x$, gives the values of the equality constraints at $x$.
- **b_eq**: array_like, optional
  1-D array of values representing the right hand side of each equality constraint (row) in $A_{eq}$.
- **bounds**: sequence, optional
  $(min, max)$ pairs for each element in $x$, defining the bounds on that parameter. Use None for one of min or max when there is no bound in that direction. By default bounds are $(0, None)$ (non-negative). If a sequence containing a single tuple is provided, then min and max will be applied to all variables in the problem.

**Returns**

A scipy.optimize.OptimizeResult consisting of the following fields:

- **x**: [ndarray]
The independent variable vector which optimizes the linear programming problem.
- **fun**: [float]
The optimal value of the objective function.
- **con**: [float]
The residuals of the equality constraints (nominally zero).
- **slack**: [ndarray]
The values of the slack variables. Each slack variable corresponds to an inequality constraint. If the slack is zero, then the corresponding constraint is active.
- **success**: [bool]
Returns True if the algorithm succeeded in finding an optimal solution.
- **status**: [int]
An integer representing the exit status of the optimization:

- $0$ : Optimization terminated successfully
- $1$ : Iteration limit reached
- $2$ : Problem appears to be infeasible
- $3$ : Problem appears to be unbounded
- $4$ : Serious numerical difficulties encountered

- **nit**: [int]
The number of iterations performed.
- **message**: [str]
A string descriptor of the exit status of the optimization.

**See also:**

For documentation for the rest of the parameters, see scipy.optimize.linprog

**Options**

- **maxiter**: int (default = 1000)
The maximum number of iterations of the algorithm.
- **disp**: bool (default = False)
Set to True if indicators of optimization status are to be printed to the console each iteration.
tol : float (default = 1e-8)
    Termination tolerance to be used for all termination criteria; see [R901]
    Section 4.5.

alpha0 : float (default = 0.99995)
    The maximal step size for Mehrota’s predictor-corrector search direction;
    see \(\beta_3\) of [R901] Table 8.1.

beta : float (default = 0.1)
    The desired reduction of the path parameter \(\mu\) (see [R903]) when Mehrota’s
    predictor-corrector is not in use (uncommon).

sparse : bool (default = False)
    Set to True if the problem is to be treated as sparse after presolve. If
    either A_eq or A_ub is a sparse matrix, this option will automatically be
    set True, and the problem will be treated as sparse even during presolve.
    If your constraint matrices contain mostly zeros and the problem is not very
    small (less than about 100 constraints or variables), consider setting True
    or providing A_eq and A_ub as sparse matrices.

ltsq : bool (default = False)
    Set to True if the problem is expected to be very poorly conditioned. This
    should always be left False unless severe numerical difficulties are en-
    countered. Leave this at the default unless you receive a warning message
    suggesting otherwise.

sym_pos : bool (default = True)
    Leave True if the problem is expected to yield a well conditioned symmet-
    ric positive definite normal equation matrix (almost always). Leave this at
    the default unless you receive a warning message suggesting otherwise.

cholesky : bool (default = True)
    Set to True if the normal equations are to be solved by explicit Cholesky
decomposition followed by explicit forward/backward substitution. This
is typically faster for moderate, dense problems that are numerically well-
behaved.

pc : bool (default = True)
    Leave True if the predictor-corrector method of Mehrota is to be used.
    This is almost always (if not always) beneficial.

ip : bool (default = False)
    Set to True if the improved initial point suggestion due to [R901] Section
4.3 is desired. Whether this is beneficial or not depends on the problem.

presolve : bool (default = True)
    Leave True if presolve routine should be run. The presolve routine is al-
most always useful because it can detect trivial infeasibilities and unbound-
edness, eliminate fixed variables, and remove redundancies. One circum-
stance in which it might be turned off (set False) is when it detects that
the problem is trivially unbounded; it is possible that the problem is
truly infeasible but this has not been detected.

rr : bool (default = True)
    Default True attempts to eliminate any redundant rows in A_eq. Set
False if A_eq is known to be of full row rank, or if you are looking
for a potential speedup (at the expense of reliability).

perm Spec : str (default = ‘MMD_AT_PLUS_A’)
    (Has effect only with sparse = True, ltsq = False, sym_pos
    = True.) A matrix is factorized in each iteration of the algorithm. This op-
tion specifies how to permute the columns of the matrix for sparsity preser-
vation. Acceptable values are:
    • NATURAL: natural ordering.
**MMD_ATA**: minimum degree ordering on the structure of $A^T A$.

**MMD_AT_PLUS_A**: minimum degree ordering on the structure of $A^T + A$.

**COLAMD**: approximate minimum degree column ordering.

This option can impact the convergence of the interior point algorithm; test different values to determine which performs best for your problem. For more information, refer to `scipy.sparse.linalg.splu`.

**Notes**

This method implements the algorithm outlined in [R901] with ideas from [R905] and a structure inspired by the simpler methods of [R903] and [R904].

First, a presolve procedure based on [R905] attempts to identify trivial infeasibilities, trivial unboundedness, and potential problem simplifications. Specifically, it checks for:

- rows of zeros in $A_{eq}$ or $A_{ub}$, representing trivial constraints;
- columns of zeros in $A_{eq}$ and $A_{ub}$, representing unconstrained variables;
- column singletons in $A_{eq}$, representing fixed variables; and
- column singletons in $A_{ub}$, representing simple bounds.

If presolve reveals that the problem is unbounded (e.g. an unconstrained and unbounded variable has negative cost) or infeasible (e.g. a row of zeros in $A_{eq}$ corresponds with a nonzero in $b_{eq}$), the solver terminates with the appropriate status code. Note that presolve terminates as soon as any sign of unboundedness is detected; consequently, a problem may be reported as unbounded when in reality the problem is infeasible (but infeasibility has not been detected yet). Therefore, if the output message states that unboundedness is detected in presolve and it is necessary to know whether the problem is actually infeasible, set option `presolve=False`.

If neither infeasibility nor unboundedness are detected in a single pass of the presolve check, bounds are tightened where possible and fixed variables are removed from the problem. Then, linearly dependent rows of the $A_{eq}$ matrix are removed, (unless they represent an infeasibility) to avoid numerical difficulties in the primary solve routine. Note that rows that are nearly linearly dependent (within a prescribed tolerance) may also be removed, which can change the optimal solution in rare cases. If this is a concern, eliminate redundancy from your problem formulation and run with option `rr=False` or `presolve=False`.

Several potential improvements can be made here: additional presolve checks outlined in [R905] should be implemented, the presolve routine should be run multiple times (until no further simplifications can be made), and more of the efficiency improvements from [R902] should be implemented in the redundancy removal routines.

After presolve, the problem is transformed to standard form by converting the (tightened) simple bounds to upper bound constraints, introducing non-negative slack variables for inequality constraints, and expressing unbounded variables as the difference between two non-negative variables.

The primal-dual path following method begins with initial ‘guesses’ of the primal and dual variables of the standard form problem and iteratively attempts to solve the (nonlinear) Karush-Kuhn-Tucker conditions for the problem with a gradually reduced logarithmic barrier term added to the objective. This particular implementation uses a homogeneous self-dual formulation, which provides certificates of infeasibility or unboundedness where applicable.

The default initial point for the primal and dual variables is that defined in [R901] Section 4.4 Equation 8.22. Optionally (by setting initial point option `ip=True`), an alternate (potentially improved) starting point can be calculated according to the additional recommendations of [R901] Section 4.4.

A search direction is calculated using the predictor-corrector method (single correction) proposed by Mehrota and detailed in [R901] Section 4.1. (A potential improvement would be to implement the method of multiple corrections described in [R901] Section 4.2.) In practice, this is accomplished by solving the normal equations, [R901] Section 5.1 Equations 8.31 and 8.32, derived from the Newton equations [R901] Section 5 Equations 8.25 (compare to [R901] Section 4 Equations 8.6-8.8). The advantage of solving the normal equations rather than 8.25 directly is that the matrices involved are symmetric positive definite, so Cholesky decomposition can be used rather than the more expensive LU factorization.
With the default `cholesky=True`, this is accomplished using `scipy.linalg.cho_factor` followed by forward/backward substitutions via `scipy.linalg.cho_solve`. With `cholesky=False` and `sym_pos=True`, Cholesky decomposition is performed instead by `scipy.linalg.solve`. Based on speed tests, this also appears to retain the Cholesky decomposition of the matrix for later use, which is beneficial as the same system is solved four times with different right hand sides in each iteration of the algorithm.

In problems with redundancy (e.g. if presolve is turned off with option `presolve=False`) or if the matrices become ill-conditioned (e.g. as the solution is approached and some decision variables approach zero), Cholesky decomposition can fail. Should this occur, successively more robust solvers (`scipy.linalg.solve` with `sym_pos=False` then `scipy.linalg.lstsq`) are tried, at the cost of computational efficiency. These solvers can be used from the outset by setting the options `sym_pos=False` and `lstsq=True`, respectively.

Note that with the option `sparse=True`, the normal equations are solved using `scipy.sparse.linalg.spsolve`. Unfortunately, this uses the more expensive LU decomposition from the outset, but for large, sparse problems, the use of sparse linear algebra techniques improves the solve speed despite the use of LU rather than Cholesky decomposition. A simple improvement would be to use the sparse Cholesky decomposition of CHOLMOD via scikit-sparse when available.

Other potential improvements for combating issues associated with dense columns in otherwise sparse problems are outlined in [R901] Section 5.3 and [R907] Section 4.1-4.2; the latter also discusses the alleviation of accuracy issues associated with the substitution approach to free variables.

After calculating the search direction, the maximum possible step size that does not activate the non-negativity constraints is calculated, and the smaller of this step size and unity is applied (as in [R901] Section 4.1.) [R901] Section 4.3 suggests improvements for choosing the step size.

The new point is tested according to the termination conditions of [R901] Section 4.5. The same tolerance, which can be set using the `tol` option, is used for all checks. (A potential improvement would be to expose the different tolerances to be set independently.) If optimality, unboundedness, or infeasibility is detected, the solve procedure terminates; otherwise it repeats.

If optimality is achieved, a postsolve procedure undoes transformations associated with presolve and converting to standard form. It then calculates the residuals (equality constraint violations, which should be very small) and slacks (difference between the left and right hand sides of the upper bound constraints) of the original problem, which are returned with the solution in an `OptimizeResult` object.

**References**

[R901], [R902], [R903], [R904], [R905], [R906], [R907]

The simplex method supports callback functions, such as:

```python
linprog_verbose_callback(xk, **kwargs)  
```

A sample callback function demonstrating the linprog callback interface.

```python
scipy.optimize.linprog_verbose_callback(xk, **kwargs)
```

A sample callback function demonstrating the linprog callback interface. This callback produces detailed output to sys.stdout before each iteration and after the final iteration of the simplex algorithm.

**Parameters**

- `xk` : array_like
  The current solution vector.

- `**kwargs` : dict
  A dictionary containing the following parameters:

  - `tableau` : array_like, the current tableau of the simplex algorithm. Its structure is defined in `solve_simplex`

  - `phase` : int, the current phase of the simplex algorithm (1 or 2)

  - `nit` : int, the current iteration number

  - `pivot` : tuple(int, int), the index of the tableau selected as the next pivot, or nan if no pivot exists
Assignment problems:

```python
scipy.optimize.linear_sum_assignment(cost_matrix)
```

Solve the linear sum assignment problem.

The linear sum assignment problem is also known as minimum weight matching in bipartite graphs. A problem instance is described by a matrix $C$, where each $C[i,j]$ is the cost of matching vertex $i$ of the first partite set (a “worker”) and vertex $j$ of the second set (a “job”). The goal is to find a complete assignment of workers to jobs of minimal cost.

Formally, let $X$ be a boolean matrix where $X[i,j] = 1$ iff row $i$ is assigned to column $j$. Then the optimal assignment has cost

$$
\min \sum_i \sum_j C_{i,j} X_{i,j}
$$

s.t. each row is assignment to at most one column, and each column to at most one row.

This function can also solve a generalization of the classic assignment problem where the cost matrix is rectangular. If it has more rows than columns, then not every row needs to be assigned to a column, and vice versa.

The method used is the Hungarian algorithm, also known as the Munkres or Kuhn-Munkres algorithm.

**Parameters**
- **cost_matrix**: array
  - The cost matrix of the bipartite graph.

**Returns**
- **row_ind**, **col_ind**: array
  - An array of row indices and one of corresponding column indices giving the optimal assignment. The cost of the assignment can be computed as `cost_matrix[row_ind, col_ind].sum()`. The row indices will be sorted; in the case of a square cost matrix they will be equal to `numpy.arange(cost_matrix.shape[0])`.

**Notes**

New in version 0.17.0.

**References**

**Examples**

```python
>>> cost = np.array([[4, 1, 3], [2, 0, 5], [3, 2, 2]])
>>> from scipy.optimize import linear_sum_assignment
```
>>> row_ind, col_ind = linear_sum_assignment(cost)
>>> col_ind
array([1, 0, 2])
>>> cost[row_ind, col_ind].sum()

scipy.optimize.approx_fprime(xk, f, epsilon, *args)
Finite-difference approximation of the gradient of a scalar function.

**Parameters**
- **xk**: array_like
  The coordinate vector at which to determine the gradient of f.
- **f**: callable
  The function of which to determine the gradient (partial derivatives).
  Should take xk as first argument, other arguments to f can be supplied in
  *args. Should return a scalar, the value of the function at xk.
- **epsilon**: array_like
  Increment to xk to use for determining the function gradient. If a scalar,
  uses the same finite difference delta for all partial derivatives. If an array,
  should contain one value per element of xk.
- ***args**: args, optional
  Any other arguments that are to be passed to f.

**Returns**
- **grad**: ndarray
  The partial derivatives of f to xk.

See also:
check_grad

**Notes**
The function gradient is determined by the forward finite difference formula:

\[
\frac{f(xk[i] + \text{epsilon}[i]) - f(xk[i])}{\text{epsilon}[i]}
\]

The main use of approx_fprime is in scalar function optimizers like fmin_bfgs, to determine numerically the Jacobian of a function.
Examples

```python
>>> from scipy import optimize
>>> def func(x, c0, c1):
    ...     "Coordinate vector `x` should be an array of size two."
    ...     return c0 * x[0]**2 + c1*x[1]**2

>>> x = np.ones(2)
>>> c0, c1 = (1, 200)
>>> eps = np.sqrt(np.finfo(float).eps)
>>> optimize.approx_fprime(x, func, [eps, np.sqrt(200) * eps], c0, c1)
array([ 2. , 400.00004198])
```

`scipy.optimize.bracket` (func, xa=0.0, xb=1.0, args=(), grow_limit=110.0, maxiter=1000)
Bracket the minimum of the function.

Given a function and distinct initial points, search in the downhill direction (as defined by the initial points) and return new points xa, xb, xc that bracket the minimum of the function f(xa) > f(xb) < f(xc). It doesn’t always mean that obtained solution will satisfy xa<=x<=xb

**Parameters**

- **func**: callable f(x,*args)
  Objective function to minimize.
- **xa, xb**: float, optional
  Bracketing interval. Defaults xa to 0.0, and xb to 1.0.
- **args**: tuple, optional
  Additional arguments (if present), passed to `func`.
- **grow_limit**: float, optional
  Maximum grow limit. Defaults to 110.0
- **maxiter**: int, optional
  Maximum number of iterations to perform. Defaults to 1000.

**Returns**

- **xa, xb, xc**: float
  Maximum number of iterations to perform. Defaults to 1000.
- **fa, fb, fc**: float
  Bracket.
- **funcalls**: int
  Objective function values in bracket.

`scipy.optimize.check_grad` (func, grad, x0, *args, **kwargs)
Check the correctness of a gradient function by comparing it against a (forward) finite-difference approximation of the gradient.

**Parameters**

- **func**: callable `func(x0, *args)`
  Function whose derivative is to be checked.
- **grad**: callable `grad(x0, *args)`
  Gradient of `func`.
- **x0**: ndarray
  Points to check `grad` against forward difference approximation of grad using `func`.
- **args**: *args, optional
  Extra arguments passed to `func` and `grad`.
- **epsilon**: float, optional
  Step size used for the finite difference approximation. It defaults to `sqrt(numpy.finfo(float).eps)`, which is approximately 1.49e-08.

**Returns**

- **err**: float
  The square root of the sum of squares (i.e. the 2-norm) of the difference between `grad(x0, *args)` and the finite difference approximation of `grad` using `func` at the points `x0`.

5.18. Optimization and root finding (`scipy.optimize`) 1073
See also:

approx_fprime

Examples

```python
>>> def func(x):
...     return x[0]**2 - 0.5 * x[1]**3
>>> def grad(x):
...     return [2 * x[0], -1.5 * x[1]**2]
>>> from scipy.optimize import check_grad
>>> check_grad(func, grad, [1.5, -1.5])
2.9802322387695312e-08
```

```python
scipy.optimize.line_search(f, myfprime, xk, pk, gfk=None, old_fval=None, old_old_fval=None, args=(), c1=0.0001, c2=0.9, amax=None, extra_condition=None, maxiter=10)
```

Find alpha that satisfies strong Wolfe conditions.

**Parameters**

- **f**: callable f(x,*args)
  Objective function.
- **myfprime**: callable f'(x,*args)
  Objective function gradient.
- **xk**: ndarray
  Starting point.
- **pk**: ndarray
  Search direction.
- **gfk**: ndarray, optional
  Gradient value for x=xk (xk being the current parameter estimate). Will be recomputed if omitted.
- **old_fval**: float, optional
  Function value for x=xk. Will be recomputed if omitted.
- **old_old_fval**: float, optional
  Function value for the point preceding x=xk
- **args**: tuple, optional
  Additional arguments passed to objective function.
- **c1**: float, optional
  Parameter for Armijo condition rule.
- **c2**: float, optional
  Parameter for curvature condition rule.
- **amax**: float, optional
  Maximum step size
- **extra_condition**: callable, optional
  A callable of the form extra_condition(alpha, x, f, g) returning a boolean. Arguments are the proposed step alpha and the corresponding x, f and g values. The line search accepts the value of alpha only if this callable returns True. If the callable returns False for the step length, the algorithm will continue with new iterates. The callable is only called for iterates satisfying the strong Wolfe conditions.
- **maxiter**: int, optional
  Maximum number of iterations to perform

**Returns**

- **alpha**: float or None
  Alpha for which x_new = x0 + alpha * pk, or None if the line search algorithm did not converge.
- **fc**: int
  Number of function evaluations made.
- **gc**: int
Number of gradient evaluations made.

**new_fval**: float or None

New function value \( f(x_{\text{new}}) = f(x_0 + \alpha \cdot pk) \), or None if the line search algorithm did not converge.

**old_fval**: float

Old function value \( f(x_0) \).

**new_slope**: float or None

The local slope along the search direction at the new value \( \langle \text{myfprime}(x_{\text{new}}), pk \rangle \), or None if the line search algorithm did not converge.

**Notes**

Uses the line search algorithm to enforce strong Wolfe conditions. See Wright and Nocedal, ‘Numerical Optimization’, 1999, pg. 59-60.

For the zoom phase it uses an algorithm by [...].

**scipy.optimize.show_options** *(solver=None, method=None, disp=True)*

Show documentation for additional options of optimization solvers.

These are method-specific options that can be supplied through the options dict.

**Parameters**

- **solver**: str
  
  Type of optimization solver. One of ‘minimize’, ‘minimize_scalar’, ‘root’, or ‘linprog’.

- **method**: str, optional
  
  If not given, shows all methods of the specified solver. Otherwise, show only the options for the specified method. Valid values corresponds to methods’ names of respective solver (e.g. ‘BFGS’ for ‘minimize’).

- **disp**: bool, optional
  
  Whether to print the result rather than returning it.

- **Returns**

  **text**: Either None (for disp=False) or the text string (disp=True)

**Notes**

The solver-specific methods are:

**scipy.optimize.minimize**

- Nelder-Mead
- Powell
- CG
- BFGS
- Newton-CG
- L-BFGS-B
- TNC
- COBYLA

- lm
- broyden1
- broyden2
- anderson
- linearmixing
class scipy.optimize.LbfgsInvHessProduct (sk, yk)

Linear operator for the L-BFGS approximate inverse Hessian.

This operator computes the product of a vector with the approximate inverse of the Hessian of the objective function, using the L-BFGS limited memory approximation to the inverse Hessian, accumulated during the optimization.

Objects of this class implement the scipy.sparse.linalg.LinearOperator interface.

Parameters

\( \mathbf{s}_k \) : array_like, shape=(n_corr, n)

Array of \( n_{corr} \) most recent updates to the solution vector. (See [1]).

\( \mathbf{y}_k \) : array_like, shape=(n_corr, n)

Array of \( n_{corr} \) most recent updates to the gradient. (See [1]).

References

[R187]

Attributes

\( \mathbf{H} \) : Hermitian adjoint.

\( \mathbf{T} \) : Transpose this linear operator.

LbfgsInvHessProduct.\( \mathbf{H} \)

Hermitian adjoint.

Returns the Hermitian adjoint of self, aka the Hermitian conjugate or Hermitian transpose. For a complex matrix, the Hermitian adjoint is equal to the conjugate transpose.

Can be abbreviated self.H instead of self.adjoint().

Returns \( \mathbf{A}_H \) : LinearOperator

Hermitian adjoint of self.

LbfgsInvHessProduct.\( \mathbf{T} \)

Transpose this linear operator.

Returns a LinearOperator that represents the transpose of this one. Can be abbreviated self.T instead of self.transpose().

Methods

\_call\_ (x)

Hermitian adjoint.

adjoint() : Hermitian adjoint.

dot (x) : Matrix-matrix or matrix-vector multiplication.

**LbfgsInvHessProduct.\_call\_**(x)

**LbfgsInvHessProduct.\_adjoint\_(\()**

Hermitian adjoint.

Returns the Hermitian adjoint of self, aka the Hermitian conjugate or Hermitian transpose. For a complex matrix, the Hermitian adjoint is equal to the conjugate transpose.

Can be abbreviated self.H instead of self.adjoint().

**Returns**

A\_H : LinearOperator

Hermitian adjoint of self.

**LbfgsInvHessProduct.\_dot\_(x)**

Matrix-matrix or matrix-vector multiplication.

**Parameters**

- x : array_like

**Returns**

A\_x : array

1-d or 2-d array, representing a vector or matrix.

1-d or 2-d array (depending on the shape of x) that represents the result of applying this linear operator on x.

**LbfgsInvHessProduct.\_matmat\_(X)**

Matrix-matrix multiplication.

Performs the operation y=A\_x where A is an MxN linear operator and x is a column vector or 1-d array.

**Parameters**

- X : {matrix, ndarray}

**Returns**

Y : {matrix, ndarray}

A matrix or ndarray with shape (M,K) depending on the type of the X argument.

**Notes**

This matmat wraps any user-specified matmat routine or overridden _matmat method to ensure that y has the correct type.

**LbfgsInvHessProduct.\_matvec\_(x)**

Matrix-vector multiplication.

Performs the operation y=A\_x where A is an MxN linear operator and x is a column vector or 1-d array.

**Parameters**

- x : {matrix, ndarray}

**Returns**

y : {matrix, ndarray}

A matrix or ndarray with shape (M,) or (M,1) depending on the type and shape of the x argument.

**Notes**

This matvec wraps the user-specified matvec routine or overridden _matvec method to ensure that y has the correct shape and type.
**Scipy Reference Guide, Release 1.0.0**

**LbfgsInvHessProduct.rmatvec(x)**
Adjoint matrix-vector multiplication.

Performs the operation \( y = A^H \times x \) where \( A \) is an \( M \times N \) linear operator and \( x \) is a column vector or 1-d array.

**Parameters**
- \( x \): {matrix, ndarray}

**Returns**
- \( y \): {matrix, ndarray}

An array with shape \((M,)\) or \((M,1)\).

A matrix or ndarray with shape \((N,)\) or \((N,1)\) depending on the type and shape of the \( x \) argument.

**Notes**
This rmatvec wraps the user-specified rmatvec routine or overridden _rmatvec method to ensure that \( y \) has the correct shape and type.

**LbfgsInvHessProduct.todense()**
Return a dense array representation of this operator.

**Returns**
- \( arr \): ndarray, shape\((n, n)\)

An array with the same shape and containing the same data represented by this LinearOperator.

**LbfgsInvHessProduct.transpose()**
Transpose this linear operator.

Returns a LinearOperator that represents the transpose of this one. Can be abbreviated self.T instead of self.transpose().

## 5.19 Nonlinear solvers

This is a collection of general-purpose nonlinear multidimensional solvers. These solvers find \( x \) for which \( F(x) = 0 \).

Both \( x \) and \( F \) can be multidimensional.

### 5.19.1 Routines

**Large-scale nonlinear solvers:**

- **newton_krylov(F, xin[, iter, rdiff, method, ...])** Find a root of a function, using Krylov approximation for inverse Jacobian.

- **anderson(F, xin[, iter, alpha, w0, M, ...])** Find a root of a function, using (extended) Anderson mixing.

**General nonlinear solvers:**

- **broyden1(F, xin[, iter, alpha, ...])** Find a root of a function, using Broyden’s first Jacobian approximation.

- **broyden2(F, xin[, iter, alpha, ...])** Find a root of a function, using Broyden’s second Jacobian approximation.

**Simple iterations:**
5.19.2 Examples

Small problem

```python
>>> def F(x):
...     return np.cos(x) + x[::-1] - [1, 2, 3, 4]
>>> import scipy.optimize
>>> x = scipy.optimize.broyden1(F, [1,1,1,1], f_tol=1e-14)
>>> x
array([ 4.04674914, 3.91158389, 2.71791677, 1.61756251])
>>> np.cos(x) + x[::-1]
array([ 1., 2., 3., 4.])
```

Large problem

Suppose that we needed to solve the following integrodifferential equation on the square \([0, 1] \times [0, 1]\):

\[
\nabla^2 P = 10 \left( \int_0^1 \int_0^1 \cosh(P) \, dx \, dy \right)^2
\]

with \(P(x, 1) = 1\) and \(P = 0\) elsewhere on the boundary of the square.

The solution can be found using the `newton_krylov` solver:

```python
import numpy as np
from scipy.optimize import newton_krylov
from numpy import cosh, zeros_like, mgrid, zeros

# parameters
nx, ny = 75, 75
hx, hy = 1./(nx-1), 1./(ny-1)

P_left, P_right = 0, 0
P_top, P_bottom = 1, 0

def residual(P):
    d2x = zeros_like(P)
    d2y = zeros_like(P)
    dx = h*1./h
    dy = h*1./h
    d2x[1:-1] = (P[2:] - 2*P[1:-1] + P[:-2]) / (hx/hx**2
    d2x[0] = (P[1] - 2*P[0] + P_left)/hx/hx
    d2x[-1] = (P_right - 2*P[-1] + P[-2])/hx/hx
    d2y[:,1:-1] = (P[:,2:] - 2*P[:,1:-1] + P[:,0])/hy/hy
    d2y[0] = (P[1] - 2*P[0] + P_left)/hx/hx
    d2y[-1] = (P_right - 2*P[-1] + P[-2])/hx/hx
    d2y[:,0] = (P[:,1] - 2*P[:,0] + P_bottom)/hy/hy
    d2y[:,1] = (P[1] - 2*P[0] + P_top)/hx/hx
    d2y[:,0] = (P[1] - 2*P[0] + P_bottom)/hy/hy
    return d2x + d2y - 10*cosh(P).mean()**2
```
# solve

guess = zeros((nx, ny), float)
sol = newton_krylov(residual, guess, method='lgmres', verbose=1)
print('Residual: %g % abs(residual(sol)).max()')

# visualize

import matplotlib.pyplot as plt

x, y = mgrid[0:1:(nx*1j), 0:1:(ny*1j)]
plt.pcolor(x, y, sol)
plt.colorbar()
plt.show()
mode : str {'full', 'valid', 'same'}, optional
A string indicating the size of the output:

- **full**: The output is the full discrete linear convolution of the inputs. (Default)
- **valid**: The output consists only of those elements that do not rely on the zero-padding. In ‘valid’ mode, either in1 or in2 must be at least as large as the other in every dimension.
- **same**: The output is the same size as in1, centered with respect to the ‘full’ output.

method : str {'auto', 'direct', 'fft'}, optional
A string indicating which method to use to calculate the convolution.

- **direct**: The convolution is determined directly from sums, the definition of convolution.
- **fft**: The Fourier Transform is used to perform the convolution by calling `fftconvolve`.
- **auto**: Automatically chooses direct or Fourier method based on an estimate of which is faster (default). See Notes for more detail.

New in version 0.19.0.

Returns

convolve : array
An N-dimensional array containing a subset of the discrete linear convolution of in1 with in2.

See also:

- `numpy.polymul` performs polynomial multiplication (same operation, but also accepts poly1d objects)
- `choose_conv_method` chooses the fastest appropriate convolution method
- `fftconvolve`

Notes

By default, convolve and correlate use method='auto', which calls choose_conv_method to choose the fastest method using pre-computed values (choose_conv_method can also measure real-world timing with a keyword argument). Because fftconvolve relies on floating point numbers, there are certain constraints that may force method=direct (more detail in choose_conv_method docstring).

Examples

Smooth a square pulse using a Hann window:

```python
>>> from scipy import signal
>>> sig = np.repeat([0., 1., 0.], 100)
>>> win = signal.hann(50)
>>> filtered = signal.convolve(sig, win, mode='same') / sum(win)
```

```python
>>> import matplotlib.pyplot as plt
>>> fig, (ax_orig, ax_win, ax_filt) = plt.subplots(3, 1, sharex=True)
>>> ax_orig.plot(sig)
>>> ax_orig.set_title('Original pulse')
>>> ax_orig.margins(0, 0.1)
>>> ax_win.plot(win)
>>> ax_win.set_title('Filter impulse response')
>>> ax_win.margins(0, 0.1)
>>> ax_filt.plot(filtered)
>>> ax_filt.set_title('Filtered signal')
>>> ax_filt.margins(0, 0.1)
```
```python
>>> fig.tight_layout()
>>> fig.show()
```

Original pulse

![Original pulse](image)

Filter impulse response

![Filter impulse response](image)

Filtered signal

![Filtered signal](image)

```python
scipy.signal.correlate(in1, in2, mode='full', method='auto')
```

Cross-correlate two N-dimensional arrays.

Cross-correlate `in1` and `in2`, with the output size determined by the `mode` argument.

**Parameters**

- `in1`: array_like
  First input.
- `in2`: array_like
  Second input. Should have the same number of dimensions as `in1`.
- `mode`: str {‘full’, ‘valid’, ‘same’}, optional
  A string indicating the size of the output:
  - `full`: The output is the full discrete linear cross-correlation of the inputs. (Default).
  - `valid`: The output consists only of those elements that do not rely on the zero-padding. In ‘valid’ mode, either `in1` or `in2` must be at least as large as the other in every dimension.
  - `same`: The output is the same size as `in1`, centered with respect to the ‘full’ output.
- `method`: str {‘auto’, ‘direct’, ‘fft’}, optional
  A string indicating which method to use to calculate the correlation:
  - `direct`: The correlation is determined directly from sums, the definition of correlation.
  - `fft`: The Fast Fourier Transform is used to perform the correlation more quickly (only available for numerical arrays.)
  - `auto`: Automatically chooses direct or Fourier method based on an estimate of which is faster (default). See `convolve` Notes for more detail.

**Returns**

- `correlate`: array
  An N-dimensional array containing a subset of the discrete linear cross-correlation of `in1` with `in2`.

See also:

- `choose_conv_method`
  contains more documentation on method.
Notes

The correlation \( z \) of two \( d \)-dimensional arrays \( x \) and \( y \) is defined as:

\[
z[\ldots, k, \ldots] = \text{sum}[\ldots, i_l, \ldots] \ x[\ldots, i_l, \ldots] \ \ast \ \text{conj}(y[\ldots, i_l - k, \ldots])
\]

This way, if \( x \) and \( y \) are 1-D arrays and \( z = \text{correlate}(x, y, \ 'full') \) then

\[
z[k] = (x \ast y)(k - N + 1) = \sum_{l=0}^{||x||-1} x_l y_{l-k+N-1}
\]

for \( k = 0, 1, \ldots, ||x|| + ||y|| - 2 \)

where \( ||x|| \) is the length of \( x \), \( N = \max(||x||, ||y||) \), and \( y_m \) is 0 when \( m \) is outside the range of \( y \).

method='fft' only works for numerical arrays as it relies on \texttt{fftconvolve}. In certain cases (i.e., arrays of objects or when rounding integers can lose precision), method='direct' is always used.

Examples

Implement a matched filter using cross-correlation, to recover a signal that has passed through a noisy channel.

```python
>>> from scipy import signal
>>> sig = np.repeat([0., 1., 1., 0., 1., 0., 0., 1.], 128)
>>> sig_noise = sig + np.random.randn(len(sig))
>>> corr = signal.correlate(sig_noise, np.ones(128), mode='same') / 128
```

```python
>>> import matplotlib.pyplot as plt
>>> clock = np.arange(64, len(sig), 128)
>>> fig, (ax_orig, ax_noise, ax_corr) = plt.subplots(3, 1, sharex=True)
>>> ax_orig.plot(sig)
>>> ax_orig.plot(clock, sig[clock], 'ro')
>>> ax_orig.set_title('Original signal')
>>> ax_noise.plot(sig_noise)
>>> ax_noise.set_title('Signal with noise')
>>> ax_corr.plot(corr)
>>> ax_corr.plot(clock, corr[clock], 'ro')
>>> ax_corr.axhline(0.5, ls=':)
>>> ax_corr.set_title('Cross-correlated with rectangular pulse')
>>> ax_orig.margins(0, 0.1)
>>> fig.tight_layout()
>>> fig.show()
```
**scipy.signal.fftconvolve** *(in1, in2, mode='full')*

Convolve two N-dimensional arrays using FFT.

Convolve *in1* and *in2* using the fast Fourier transform method, with the output size determined by the *mode* argument.

This is generally much faster than *convolve* for large arrays (n > ~500), but can be slower when only a few output values are needed, and can only output float arrays (int or object array inputs will be cast to float).

As of v0.19, *convolve* automatically chooses this method or the direct method based on an estimation of which is faster.

**Parameters**

- **in1**: array_like
  First input.
- **in2**: array_like
  Second input. Should have the same number of dimensions as *in1*. If operating in ‘valid’ mode, either *in1* or *in2* must be at least as large as the other in every dimension.
- **mode**: str {'full', 'valid', 'same'}, optional
  A string indicating the size of the output:
  - **full**: The output is the full discrete linear convolution of the inputs. (Default)
  - **valid**: The output consists only of those elements that do not rely on the zero-padding.
  - **same**: The output is the same size as *in1*, centered with respect to the ‘full’ output.

**Returns**

- **out**: array
  An N-dimensional array containing a subset of the discrete linear convolution of *in1* with *in2*.

**Examples**

Autocorrelation of white noise is an impulse.

```python
>>> from scipy import signal
>>> sig = np.random.randn(1000)
>>> autocorr = signal.fftconvolve(sig, sig[::-1], mode='full')
```
Gaussian blur implemented using FFT convolution. Notice the dark borders around the image, due to the zero-padding beyond its boundaries. The `convolve2d` function allows for other types of image boundaries, but is far slower.

```python
>>> from scipy import misc
>>> face = misc.face(gray=True)
>>> kernel = np.outer(signal.gaussian(70, 8), signal.gaussian(70, 8))
>>> blurred = signal.fftconvolve(face, kernel, mode='same')

>>> fig, (ax_orig, ax_kernel, ax_blurred) = plt.subplots(3, 1, figsize=(6, 15))
>>> ax_orig.imshow(face, cmap='gray')
>>> ax_orig.set_title('Original')
>>> ax_orig.set_axis_off()
>>> ax_kernel.imshow(kernel, cmap='gray')
>>> ax_kernel.set_title('Gaussian kernel')
>>> ax_kernel.set_axis_off()
>>> ax_blurred.imshow(blurred, cmap='gray')
>>> ax_blurred.set_title('Blurred')
>>> ax_blurred.set_axis_off()
>>> fig.show()
```
Original

Gaussian kernel

Blurred
`scipy.signal.convolve2d(in1, in2, mode='full', boundary='fill', fillvalue=0)`

Convolves two 2-dimensional arrays.

Convolves `in1` and `in2` with output size determined by `mode`, and boundary conditions determined by `boundary` and `fillvalue`.

**Parameters**

- **in1**: array_like
  - First input.
- **in2**: array_like
  - Second input. Should have the same number of dimensions as `in1`. If operating in ‘valid’ mode, either `in1` or `in2` must be at least as large as the other in every dimension.
- **mode**: str {'full', 'valid', 'same'}, optional
  - A string indicating the size of the output:
    - full: The output is the full discrete linear convolution of the inputs. (Default)
    - valid: The output consists only of those elements that do not rely on the zero-padding.
    - same: The output is the same size as `in1`, centered with respect to the ‘full’ output.
- **boundary**: str {'fill', 'wrap', 'symm'}, optional
  - A flag indicating how to handle boundaries:
    - fill: pad input arrays with `fillvalue`. (default)
    - wrap: circular boundary conditions.
    - symm: symmetrical boundary conditions.
- **fillvalue**: scalar, optional
  - Value to fill pad input arrays with. Default is 0.

**Returns**

- **out**: ndarray
  - A 2-dimensional array containing a subset of the discrete linear convolution of `in1` with `in2`.

**Examples**

Compute the gradient of an image by 2D convolution with a complex Scharr operator. (Horizontal operator is real, vertical is imaginary.) Use symmetric boundary condition to avoid creating edges at the image boundaries.

```python
>>> from scipy import signal
>>> from scipy import misc
>>> ascent = misc.ascent()
>>> scharr = np.array([[ -3-3j, 0-10j, +3 -3j],
                    [ -10+0j, 0+ 0j, +10 +0j],
                    [ -3+3j, 0+10j, +3 +3j]]) # Gx + j*Gy
>>> grad = signal.convolve2d(ascent, scharr, boundary='symm', mode='same')
```

```python
>>> import matplotlib.pyplot as plt
>>> fig, (ax_orig, ax_mag, ax_ang) = plt.subplots(3, 1, figsize=(6, 15))
>>> ax_orig.imshow(ascent, cmap='gray')
>>> ax_orig.set_title('Original')
>>> ax_orig.set_axis_off()
>>> ax_mag.imshow(np.absolute(grad), cmap='gray')
>>> ax_mag.set_title('Gradient magnitude')
>>> ax_mag.set_axis_off()
>>> ax_ang.imshow(np.angle(grad), cmap='hsv') # hsv is cyclic, like angles
>>> ax_ang.set_title('Gradient orientation')
>>> ax_ang.set_axis_off()
>>> fig.show()
```
Original

Gradient magnitude

Gradient orientation
scipy.signal.correlate2d(in1, in2, mode='full', boundary='fill', fillvalue=0)

Cross-correlate two 2-dimensional arrays.

Cross correlate in1 and in2 with output size determined by mode, and boundary conditions determined by boundary and fillvalue.

**Parameters**

- **in1**: array_like
  First input.

- **in2**: array_like
  Second input. Should have the same number of dimensions as in1. If operating in ‘valid’ mode, either in1 or in2 must be at least as large as the other in every dimension.

- **mode**: str {'full', 'valid', 'same'}, optional
  A string indicating the size of the output:
  - full: The output is the full discrete linear cross-correlation of the inputs. (Default)
  - valid: The output consists only of those elements that do not rely on the zero-padding.
  - same: The output is the same size as in1, centered with respect to the ‘full’ output.

- **boundary**: str {'fill', 'wrap', 'symm'}, optional
  A flag indicating how to handle boundaries:
  - fill: pad input arrays with fillvalue. (default)
  - wrap: circular boundary conditions.
  - symm: symmetrical boundary conditions.

- **fillvalue**: scalar, optional
  Value to fill pad input arrays with. Default is 0.

**Returns**

- **correlate2d**: ndarray
  A 2-dimensional array containing a subset of the discrete linear cross-correlation of in1 with in2.

**Examples**

Use 2D cross-correlation to find the location of a template in a noisy image:

```python
>>> from scipy import signal
>>> from scipy import misc

>>> face = misc.face(gray=True) - misc.face(gray=True).mean()
>>> template = np.copy(face[300:365, 670:750])  # right eye
>>> template -= template.mean()
>>> face = face + np.random.randn(*face.shape) * 50  # add noise
>>> corr = signal.correlate2d(face, template, boundary='symm', mode='same')
>>> y, x = np.unravel_index(np.argmax(corr), corr.shape)  # find the match

>>> import matplotlib.pyplot as plt

>>> fig, (ax_orig, ax_template, ax_corr) = plt.subplots(3, 1, figsize=(6, 15))

>>> ax_orig.imshow(face, cmap='gray')
>>> ax_orig.set_title('Original')
>>> ax_orig.set_axis_off()

>>> ax_template.imshow(template, cmap='gray')
>>> ax_template.set_title('Template')
>>> ax_template.set_axis_off()

>>> ax_corr.imshow(corr, cmap='gray')
>>> ax_corr.set_title('Cross-correlation')
>>> ax_corr.set_axis_off()

>>> ax_orig.plot(x, y, 'ro')
>>> fig.show()
```
Original

Template

Cross-correlation
scipy.signal.sepfir2d(input, hrow, hcol) → output

Description:
Convolve the rank-2 input array with the separable filter defined by the rank-1 arrays hrow, and hcol. Mirror symmetric boundary conditions are assumed. This function can be used to find an image given its B-spline representation.

scipy.signal.choose_conv_method(in1, in2, mode='full', measure=False)

Find the fastest convolution/correlation method.
This primarily exists to be called during the method='auto' option in convolve and correlate, but can also be used when performing many convolutions of the same input shapes and dtypes, determining which method to use for all of them, either to avoid the overhead of the 'auto' option or to use accurate real-world measurements.

Parameters
- in1 : array_like
  The first argument passed into the convolution function.
- in2 : array_like
  The second argument passed into the convolution function.
- mode : str {'full', 'valid', 'same'}, optional
  A string indicating the size of the output:
  - full: The output is the full discrete linear convolution of the inputs. (Default)
  - valid: The output consists only of those elements that do not rely on the zero-padding.
  - same: The output is the same size as in1, centered with respect to the 'full' output.
- measure : bool, optional
  If True, run and time the convolution of in1 and in2 with both methods and return the fastest. If False (default), predict the fastest method using precomputed values.

Returns
- method : str
  A string indicating which convolution method is fastest, either 'direct' or 'fft'
- times : dict, optional
  A dictionary containing the times (in seconds) needed for each method. This value is only returned if measure=True.

See also:
convolve, correlate

Notes
For large n, measure=False is accurate and can quickly determine the fastest method to perform the convolution. However, this is not as accurate for small n (when any dimension in the input or output is small).

In practice, we found that this function estimates the faster method up to a multiplicative factor of 5 (i.e., the estimated method is at most 5 times slower than the fastest method). The estimation values were tuned on an early 2015 MacBook Pro with 8GB RAM but we found that the prediction held fairly accurately across different machines.

If measure=True, time the convolutions. Because this function uses fftconvolve, an error will be thrown if it does not support the inputs. There are cases when fftconvolve supports the inputs but this function returns direct (e.g., to protect against floating point integer precision).

New in version 0.19.

Examples
Estimate the fastest method for a given input:
```python
>>> from scipy import signal
>>> a = np.random.randn(1000)
>>> b = np.random.randn(1000000)
>>> method = signal.choose_conv_method(a, b, mode='same')
>>> method
'fft'
```

This can then be applied to other arrays of the same dtype and shape:

```python
>>> c = np.random.randn(1000)
>>> d = np.random.randn(1000000)
>>> # `method` works with correlate and convolve
>>> corr1 = signal.correlate(a, b, mode='same', method=method)
>>> corr2 = signal.correlate(c, d, mode='same', method=method)
>>> conv1 = signal.convolve(a, b, mode='same', method=method)
>>> conv2 = signal.convolve(c, d, mode='same', method=method)
```

**scipy.signal.bspline(x, n)**

B-spline basis function of order n.

**Notes**

Uses numpy.piecewise and automatic function-generator.

**scipy.signal.cubic(x)**

A cubic B-spline.

This is a special case of `bspline`, and equivalent to `bspline(x, 3)`.

**scipy.signal.quadratic(x)**

A quadratic B-spline.

This is a special case of `bspline`, and equivalent to `bspline(x, 2)`.

**scipy.signal.gauss_spline(x, n)**

Gaussian approximation to B-spline basis function of order n.

**scipy.signal.cspline1d(signal, lamb=0.0)**

Compute cubic spline coefficients for rank-1 array.
Find the cubic spline coefficients for a 1-D signal assuming mirror-symmetric boundary conditions. To obtain the signal back from the spline representation mirror-symmetric-convolve these coefficients with a length 3 FIR window $[1.0, 4.0, 1.0] / 6.0$.

**Parameters**
- **signal**: ndarray
  A rank-1 array representing samples of a signal.
- **lamb**: float, optional
  Smoothing coefficient, default is 0.0.

**Returns**
- **c**: ndarray
  Cubic spline coefficients.

```python
scipy.signal.qspline1d(signal, lamb=0.0)
```

Compute quadratic spline coefficients for rank-1 array.

Find the quadratic spline coefficients for a 1-D signal assuming mirror-symmetric boundary conditions. To obtain the signal back from the spline representation mirror-symmetric-convolve these coefficients with a length 3 FIR window $[1.0, 6.0, 1.0] / 8.0$.

**Parameters**
- **signal**: ndarray
  A rank-1 array representing samples of a signal.
- **lamb**: float, optional
  Smoothing coefficient (must be zero for now).

**Returns**
- **c**: ndarray
  Cubic spline coefficients.

```python
scipy.signal.cspline2d(input, lambda, precision)
```

Return the third-order B-spline coefficients over a regularly spaced input grid for the two-dimensional input image. The lambda argument specifies the amount of smoothing. The precision argument allows specifying the precision used when computing the infinite sum needed to apply mirror-symmetric boundary conditions.

```python
scipy.signal.qspline2d(input, lambda, precision)
```

Return the second-order B-spline coefficients over a regularly spaced input grid for the two-dimensional input image. The lambda argument specifies the amount of smoothing. The precision argument allows specifying the precision used when computing the infinite sum needed to apply mirror-symmetric boundary conditions.

```python
scipy.signal.csplined_eval(cj, newx, dx=1.0, x0=0)
```

Evaluate a spline at the new set of points.

$dx$ is the old sample-spacing while $x0$ was the old origin. In other-words the old-sample points (knot-points) for which the $cj$ represent spline coefficients were at equally-spaced points of:

$$oldx = x0 + j*dx \; j=0\ldots N-1, \text{with} \; N=\text{len}(cj)$$

Edges are handled using mirror-symmetric boundary conditions.

```python
scipy.signal.qsplined_eval(cj, newx, dx=1.0, x0=0)
```

Evaluate a quadratic spline at the new set of points.

$dx$ is the old sample-spacing while $x0$ was the old origin. In other-words the old-sample points (knot-points) for which the $cj$ represent spline coefficients were at equally-spaced points of:

$$oldx = x0 + j*dx \; j=0\ldots N-1, \text{with} \; N=\text{len}(cj)$$

Edges are handled using mirror-symmetric boundary conditions.
scipy.signal.spline_filter (Iin, lmbda=5.0)
Smoothing spline (cubic) filtering of a rank-2 array.
Filter an input dataset, \( I_{\text{in}} \), using a (cubic) smoothing spline of fall-off \( lmbda \).

</tbody>
</table>

scipy.signal.order_filter(a, domain, rank)
Perform an order filter on an N-dimensional array.
Perform an order filter on the array \( a \). The domain argument acts as a mask centered over each pixel. The non-zero elements of domain are used to select elements surrounding each input pixel which are placed in a list. The list is sorted, and the output for that pixel is the element corresponding to rank in the sorted list.

**Parameters**
- **a** : ndarray
  The N-dimensional input array.
- **domain** : array_like
  A mask array with the same number of dimensions as \( a \). Each dimension should have an odd number of elements.
rank : int
A non-negative integer which selects the element from the sorted list (0

corresponds to the smallest element, 1 is the next smallest element, etc.).

Returns: out : ndarray
The results of the order filter in an array with the same shape as a.

Examples

```python
>>> from scipy import signal
>>> x = np.arange(25).reshape(5, 5)
>>> domain = np.identity(3)
>>> x
array([[ 0, 1, 2, 3, 4],
       [ 5, 6, 7, 8, 9],
       [10, 11, 12, 13, 14],
       [15, 16, 17, 18, 19],
       [20, 21, 22, 23, 24]])
>>> signal.order_filter(x, domain, 0)
array([[ 0., 0., 0., 0., 0.],
       [ 0., 0., 1., 2., 0.],
       [ 0., 5., 6., 7., 0.],
       [ 0., 10., 11., 12., 0.],
       [ 0., 0., 0., 0., 0.]])
>>> signal.order_filter(x, domain, 2)
array([[ 6., 7., 8., 9., 4.],
       [16., 17., 18., 19., 14.],
       [21., 22., 23., 24., 19.],
       [20., 21., 22., 23., 24.]])
```

scipy.signal.medfilt(volume, kernel_size=None)
Perform a median filter on an N-dimensional array.

Apply a median filter to the input array using a local window-size given by kernel_size.

Parameters:

- volume : array_like
  An N-dimensional input array.
- kernel_size : array_like, optional
  A scalar or an N-length list giving the size of the median filter window in each dimension. Elements of kernel_size should be odd. If kernel_size is a scalar, then this scalar is used as the size in each dimension. Default size is 3 for each dimension.

Returns:

- out : ndarray
  An array the same size as input containing the median filtered result.

scipy.signal.medfilt2d(input, kernel_size=3)
Median filter a 2-dimensional array.

Apply a median filter to the input array using a local window-size given by kernel_size (must be odd).

Parameters:

- input : array_like
  A 2-dimensional input array.
- kernel_size : array_like, optional
  A scalar or a list of length 2, giving the size of the median filter window in each dimension. Elements of kernel_size should be odd. If kernel_size is a scalar, then this scalar is used as the size in each dimension. Default is a kernel of size (3, 3).

Returns:

- out : ndarray
  An array the same size as input containing the median filtered result.
scipy.signal.wiener (im, mysize=None, noise=None)

Perform a Wiener filter on an N-dimensional array.

Apply a Wiener filter to the N-dimensional array `im`.

**Parameters**
- `im` : ndarray
  An N-dimensional array.
- `mysize` : int or array_like, optional
  A scalar or an N-length list giving the size of the Wiener filter window in each dimension. Elements of `mysize` should be odd. If `mysize` is a scalar, then this scalar is used as the size in each dimension.
- `noise` : float, optional
  The noise-power to use. If None, then noise is estimated as the average of the local variance of the input.

**Returns**
- `out` : ndarray
  Wiener filtered result with the same shape as `im`.

scipy.signal.symiirorder1 (input, c0, z1, precision) → output

Implement a smoothing IIR filter with mirror-symmetric boundary conditions using a cascade of first-order sections. The second section uses a reversed sequence. This implements a system with the following transfer function and mirror-symmetric boundary conditions:

\[
H(z) = \frac{c0}{(1-z1/z) (1 - z1 z)}
\]

The resulting signal will have mirror symmetric boundary conditions as well.

**Parameters**
- `input` : ndarray
  The input signal.
- `c0, z1` : scalar
  Parameters in the transfer function.
- `precision` : scalar
  Specifies the precision for calculating initial conditions of the recursive filter based on mirror-symmetric input.

**Returns**
- `output` : ndarray
  The filtered signal.

scipy.signal.symiirorder2 (input, r, omega, precision) → output

Implement a smoothing IIR filter with mirror-symmetric boundary conditions using a cascade of second-order sections. The second section uses a reversed sequence. This implements the following transfer function:

\[
H(z) = \frac{cs^2}{(1 - a2/z - a3/z^2) (1 - a2 z - a3 z^2 )}
\]

where:

\[
a2 = (2 \, r \cos \omega)
a3 = - r^2
cs = 1 - 2 \, r \cos \omega + r^2
\]

**Parameters**
- `input` : ndarray
  The input signal.
- `r, omega` : scalar
  Parameters in the transfer function.
- `precision` : scalar
  Specifies the precision for calculating initial conditions of the recursive filter based on mirror-symmetric input.
Specifies the precision for calculating initial conditions of the recursive filter based on mirror-symmetric input.

Returns

- **output**: ndarray
  The filtered signal.

**scipy.signal.lfilter** *(b, a, axis=-1, zi=None)*

Filter data along one-dimension with an IIR or FIR filter.

Filter a data sequence, `x`, using a digital filter. This works for many fundamental data types (including Object type). The filter is a direct form II transposed implementation of the standard difference equation (see Notes).

**Parameters**

- **b**: array_like
  The numerator coefficient vector in a 1-D sequence.
- **a**: array_like
  The denominator coefficient vector in a 1-D sequence. If `a[0]` is not 1, then both `a` and `b` are normalized by `a[0]`.
- **x**: array_like
  An N-dimensional input array.
- **axis**: int, optional
  The axis of the input data array along which to apply the linear filter. The filter is applied to each subarray along this axis. Default is -1.
- **zi**: array_like, optional
  Initial conditions for the filter delays. It is a vector (or array of vectors for an N-dimensional input) of length `max(len(a), len(b)) - 1`. If `zi` is None or is not given then initial rest is assumed. See `lfiltic` for more information.

**Returns**

- **y**: array
  The output of the digital filter.
- **zf**: array, optional
  If `zi` is None, this is not returned, otherwise, `zf` holds the final filter delay values.

See also:

- `lfiltic` Construct initial conditions for `lfilter`.
- `lfilter_zi` Compute initial state (steady state of step response) for `lfilter`.
- `filtfilt` A forward-backward filter, to obtain a filter with linear phase.
- `savgol_filter` A Savitzky-Golay filter.
- `sosfilt` Filter data using cascaded second-order sections.
- `sosfiltfilt` A forward-backward filter using second-order sections.

**Notes**

The filter function is implemented as a direct II transposed structure. This means that the filter implements:

\[
\begin{align*}
&\quad - a[1]y[n-1] - \ldots - a[N]y[n-N]
\end{align*}
\]

where `M` is the degree of the numerator, `N` is the degree of the denominator, and `n` is the sample number. It is implemented using the following difference equations (assuming `M = N`):

\[
\begin{align*}
a[0]y[n] &= b[0]x[n] + d[0][n-1] \\
&\quad \ldots
\end{align*}
\]
\[ \begin{align*}
\text{d}[N-2][n] &= b[N-1] \times x[n] - a[N-1] \times y[n] + d[N-1][n-1] \\
\text{d}[N-1][n] &= b[N] \times x[n] - a[N] \times y[n]
\end{align*} \]

where \( d \) are the state variables.

The rational transfer function describing this filter in the z-transform domain is:

\[
Y(z) = \frac{-1 - M}{-1 - N} \frac{b[0] + b[1]z + \ldots + b[M] \cdot z^{-M}}{a[0] + a[1]z + \ldots + a[N] \cdot z^{-N}} X(z)
\]

**Examples**

Generate a noisy signal to be filtered:

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> t = np.linspace(-1, 1, 201)
>>> x = (np.sin(2*np.pi*0.75*t*(1-t) + 2.1) +
...     0.1*np.sin(2*np.pi*1.25*t + 1) +
...     0.18*np.cos(2*np.pi*3.85*t))
>>> xn = x + np.random.randn(len(t)) * 0.08

Create an order 3 lowpass butterworth filter:

```python
>>> b, a = signal.butter(3, 0.05)
```  
Apply the filter to \( x_n \). Use \texttt{lfiltel\textunderscore zi} to choose the initial condition of the filter:

```python
>>> zi = signal.lfilter\_zi(b, a)
>>> z, _ = signal.lfilter(b, a, xn, zi=zi*xn[0])

Apply the filter again, to have a result filtered at an order the same as \texttt{filt\_filt}:

```python
>>> z2, _ = signal.lfilter(b, a, z, zi=zi*z[0])
```

Use \texttt{filt\_filt} to apply the filter:

```python
>>> y = signal.filtfilt(b, a, xn)
```

Plot the original signal and the various filtered versions:

```python
>>> plt.figure
>>> plt.plot(t, xn, 'b', alpha=0.75)
>>> plt.plot(t, z, 'r--', t, z2, 'r', t, y, 'k')
>>> plt.legend(('noisy signal', 'lfilter, once', 'lfilter, twice', 'filt\_filt'), loc='best')
>>> plt.grid(True)
>>> plt.show()
```
scipy.signal.lfiltic(b, a, y, x=None)

Construct initial conditions for lfilter given input and output vectors.

Given a linear filter \((b, a)\) and initial conditions on the output \(y\) and the input \(x\), return the initial conditions on the state vector \(zi\) which is used by \(lfilter\) to generate the output given the input.

**Parameters**

- **b**: array_like
  - Linear filter term.
- **a**: array_like
  - Linear filter term.
- **y**: array_like
  - Initial conditions.
    - If \(N = \text{len}(a) - 1\), then \(y = \{y[-1], y[-2], \ldots, y[-N]\}\).
    - If \(y\) is too short, it is padded with zeros.
- **x**: array_like, optional
  - Initial conditions.
    - If \(M = \text{len}(b) - 1\), then \(x = \{x[-1], x[-2], \ldots, x[-M]\}\).
    - If \(x\) is not given, its initial conditions are assumed zero.
    - If \(x\) is too short, it is padded with zeros.

**Returns**

- **zi**: ndarray
  - The state vector \(zi = \{z_0[-1], z_1[-1], \ldots, z_{K-1}[-1]\}\), where \(K = \max(M, N)\).

See also:

- lfilter, lfilter_zi

scipy.signal.lfilter_zi(b, a)

Construct initial conditions for lfilter for step response steady-state.

Compute an initial state \(zi\) for the \(lfilter\) function that corresponds to the steady state of the step response.

A typical use of this function is to set the initial state so that the output of the filter starts at the same value as the first element of the signal to be filtered.

**Parameters**

- **b, a**: array_like (1-D)

**Returns**

- **zi**: 1-D ndarray
  - The initial state for the filter.
See also:

`lfilter`, `lfiltic`, `filtfilt`

Notes

A linear filter with order m has a state space representation (A, B, C, D), for which the output y of the filter can be expressed as:

\[
\begin{align*}
    z(n+1) &= A \cdot z(n) + B \cdot x(n) \\
    y(n)   &= C \cdot z(n) + D \cdot x(n)
\end{align*}
\]

where z(n) is a vector of length m, A has shape (m, m), B has shape (m, 1), C has shape (1, m) and D has shape (1, 1) (assuming x(n) is a scalar). `ifilter_zi` solves:

\[
    z_i = A \cdot z_i + B
\]

In other words, it finds the initial condition for which the response to an input of all ones is a constant.

Given the filter coefficients a and b, the state space matrices for the transposed direct form II implementation of the linear filter, which is the implementation used by `scipy.signal.lfilter`, are:

\[
\begin{align*}
    A &= \text{scipy.linalg.companion(a)}^T \\
    B &= b[1:] - a[1:] \cdot b[0]
\end{align*}
\]

assuming a[0] is 1.0; if a[0] is not 1, a and b are first divided by a[0].

Examples

The following code creates a lowpass Butterworth filter. Then it applies that filter to an array whose values are all 1.0; the output is also all 1.0, as expected for a lowpass filter. If the zi argument of `lfilter` had not been given, the output would have shown the transient signal.

```python
>>> from numpy import array, ones
>>> from scipy.signal import lfilter, lfilter_zi, butter

>>> b, a = butter(5, 0.25)
>>> zi = lfilter_zi(b, a)
>>> y, zo = lfilter(b, a, ones(10), zi=zi)
>>> y
array([1., 1., 1., 1., 1., 1., 1., 1., 1., 1.])
```

Another example:

```python
>>> x = array([0.5, 0.5, 0.5, 0.0, 0.0, 0.0, 0.0, 0.0])
>>> y, zf = lfilter(b, a, x, zi=zi*x[0])
>>> y
array([ 0.5 , 0.5 , 0.5 , 0.49836039, 0.48610528,
        0.44399389, 0.35505241])
```

Note that the zi argument to `lfilter` was computed using `lfilter_zi` and scaled by x[0]. Then the output y has no transient until the input drops from 0.5 to 0.0.

```
scipy.signal.filtfilt(b, a, x, axis=-1, padtype='odd', padlen=None, method='pad', irlen=None)
```

Apply a digital filter forward and backward to a signal.

This function applies a linear digital filter twice, once forward and once backwards. The combined filter has zero phase and a filter order twice that of the original.

The function provides options for handling the edges of the signal.

Parameters

- **b**: (N,) array_like
The numerator coefficient vector of the filter.

\[ a : (N,) \text{ array_like} \]

The denominator coefficient vector of the filter. If \( a[0] \) is not 1, then both \( a \) and \( b \) are normalized by \( a[0] \).

\[ x : \text{array_like} \]

The array of data to be filtered.

\[ \text{axis} : \text{int, optional} \]

The axis of \( x \) to which the filter is applied. Default is -1.

\[ \text{padtype} : \text{str or None, optional} \]

Must be ‘odd’, ‘even’, ‘constant’, or None. This determines the type of extension to use for the padded signal to which the filter is applied. If \( \text{padtype} \) is None, no padding is used. The default is ‘odd’.

\[ \text{padlen} : \text{int or None, optional} \]

The number of elements by which to extend \( x \) at both ends of \( \text{axis} \) before applying the filter. This value must be less than \( x.\text{shape}[\text{axis}] - 1 \). \( \text{padlen}=0 \) implies no padding. The default value is \( 3 \times \max(\text{len}(a), \text{len}(b)) \).

\[ \text{method} : \text{str, optional} \]

Determines the method for handling the edges of the signal, either “pad” or “gust”. When \( \text{method} \) is “pad”, the signal is padded; the type of padding is determined by \( \text{padtype} \) and \( \text{padlen} \), and \( \text{irlen} \) is ignored. When \( \text{method} \) is “gust”, Gustafsson’s method is used, and \( \text{padtype} \) and \( \text{padlen} \) are ignored.

\[ \text{irlen} : \text{int or None, optional} \]

When \( \text{method} \) is “gust”, \( \text{irlen} \) specifies the length of the impulse response of the filter. If \( \text{irlen} \) is None, no part of the impulse response is ignored. For a long signal, specifying \( \text{irlen} \) can significantly improve the performance of the filter.

\[ \text{Returns} \]

\[ y : \text{ndarray} \]

The filtered output with the same shape as \( x \).

See also:

sosfiltfilt, lfilter_zi, lfilter, lfilteric, savgol_filter, sosfilt

Notes

When \( \text{method} \) is “pad”, the function pads the data along the given axis in one of three ways: odd, even or constant. The odd and even extensions have the corresponding symmetry about the end point of the data. The constant extension extends the data with the values at the end points. On both the forward and backward passes, the initial condition of the filter is found by using \( \text{lfilter_zi} \) and scaling it by the end point of the extended data.

When \( \text{method} \) is “gust”, Gustafsson’s method [R252] is used. Initial conditions are chosen for the forward and backward passes so that the forward-backward filter gives the same result as the backward-forward filter.

The option to use Gustafsson’s method was added in scipy version 0.16.0.

References

[R252]

Examples

The examples will use several functions from scipy.signal.

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```
First we create a one second signal that is the sum of two pure sine waves, with frequencies 5 Hz and 250 Hz, sampled at 2000 Hz.

```python
>>> t = np.linspace(0, 1.0, 2001)
>>> xlow = np.sin(2 * np.pi * 5 * t)
>>> xhigh = np.sin(2 * np.pi * 250 * t)
>>> x = xlow + xhigh
```

Now create a lowpass Butterworth filter with a cutoff of 0.125 times the Nyquist rate, or 125 Hz, and apply it to `x` with `filtfilt`. The result should be approximately `xlow`, with no phase shift.

```python
>>> b, a = signal.butter(8, 0.125)
>>> y = signal.filtfilt(b, a, x, padlen=150)
>>> np.abs(y - xlow).max()
8.1086182074789912e-06
```

We get a fairly clean result for this artificial example because the odd extension is exact, and with the moderately long padding, the filter’s transients have dissipated by the time the actual data is reached. In general, transient effects at the edges are unavoidable.

The following example demonstrates the option `method="gust"`. First, create a filter.

```python
>>> b, a = signal.ellip(4, 0.01, 120, 0.125)  # Filter to be applied.
>>> np.random.seed(123456)
```

`sig` is a random input signal to be filtered.

```python
>>> n = 60
>>> sig = np.random.randn(n)**3 + 3*np.random.randn(n).cumsum()
```

Apply `filtfilt` to `sig`, once using the Gustafsson method, and once using padding, and plot the results for comparison.

```python
>>> fgust = signal.filtfilt(b, a, sig, method="gust")
>>> fpad = signal.filtfilt(b, a, sig, padlen=50)
>>> plt.plot(sig, 'k-', label='input')
>>> plt.plot(fgust, 'b-', linewidth=4, label='gust')
>>> plt.plot(fpad, 'c-', linewidth=1.5, label='pad')
>>> plt.legend(loc='best')
>>> plt.show()
```
The `irlen` argument can be used to improve the performance of Gustafsson’s method.

Estimate the impulse response length of the filter.

```python
>>> z, p, k = signal.tf2zpk(b, a)
>>> eps = 1e-9
>>> r = np.max(np.abs(p))
>>> approx_impulse_len = int(np.ceil(np.log(eps) / np.log(r)))
>>> approx_impulse_len
137
```

Apply the filter to a longer signal, with and without the `irlen` argument. The difference between `y1` and `y2` is small. For long signals, using `irlen` gives a significant performance improvement.

```python
>>> x = np.random.randn(5000)
>>> y1 = signal.filtfilt(b, a, x, method='gust')
>>> y2 = signal.filtfilt(b, a, x, method='gust', irlen=approx_impulse_len)
>>> print(np.max(np.abs(y1 - y2)))
1.80056858312e-10
```

`scipy.signal.savgol_filter(x, window_length, polyorder, deriv=0, delta=1.0, axis=-1, mode='interp', cval=0.0)`

Apply a Savitzky-Golay filter to an array.

This is a 1-d filter. If `x` has dimension greater than 1, `axis` determines the axis along which the filter is applied.

**Parameters**

- `x` : array_like
  The data to be filtered. If `x` is not a single or double precision floating point array, it will be converted to type `numpy.float64` before filtering.

- `window_length` : int
  The length of the filter window (i.e. the number of coefficients). `window_length` must be a positive odd integer. If `mode` is ‘interp’, `window_length` must be less than or equal to the size of `x`.

- `polyorder` : int
  The order of the polynomial used to fit the samples. `polyorder` must be less than `window_length`.

- `deriv` : int, optional
The order of the derivative to compute. This must be a nonnegative integer. The default is 0, which means to filter the data without differentiating.

**delta** : float, optional
The spacing of the samples to which the filter will be applied. This is only used if deriv > 0. Default is 1.0.

**axis** : int, optional
The axis of the array \( x \) along which the filter is to be applied. Default is -1.

**mode** : str, optional
Must be ‘mirror’, ‘constant’, ‘nearest’, ‘wrap’ or ‘interp’. This determines the type of extension to use for the padded signal to which the filter is applied. When mode is ‘constant’, the padding value is given by \( cval \). See the Notes for more details on ‘mirror’, ‘constant’, ‘wrap’, and ‘nearest’. When the ‘interp’ mode is selected (the default), no extension is used. Instead, a degree \( polyorder \) polynomial is fit to the last \( \text{window}_\text{length} \) values of the edges, and this polynomial is used to evaluate the last \( \text{window}_\text{length} // 2 \) output values.

**cval** : scalar, optional
Value to fill past the edges of the input if \( \text{mode} \) is ‘constant’. Default is 0.0.

**Returns**
\( y \) : ndarray, same shape as \( x \)
The filtered data.

See also:
savgol_coeffs

Notes
Details on the \( \text{mode} \) options:

- **‘mirror’**: Repeats the values at the edges in reverse order. The value closest to the edge is not included.
- **‘nearest’**: The extension contains the nearest input value.
- **‘constant’**: The extension contains the value given by the \( cval \) argument.
- **‘wrap’**: The extension contains the values from the other end of the array.

For example, if the input is \([1, 2, 3, 4, 5, 6, 7, 8]\), and \( \text{window}_\text{length} \) is 7, the following shows the extended data for the various \( \text{mode} \) options (assuming \( cval \) is 0):

<table>
<thead>
<tr>
<th>mode</th>
<th>Ext</th>
<th>Input</th>
<th>Ext</th>
</tr>
</thead>
<tbody>
<tr>
<td>'mirror'</td>
<td>4</td>
<td>4 3 2</td>
<td>1</td>
</tr>
<tr>
<td>'nearest'</td>
<td>1</td>
<td>1 1 1</td>
<td>1</td>
</tr>
<tr>
<td>'constant'</td>
<td>0</td>
<td>0 0 0</td>
<td>1</td>
</tr>
<tr>
<td>'wrap'</td>
<td>6</td>
<td>7</td>
<td>8</td>
</tr>
</tbody>
</table>

New in version 0.14.0.

Examples

```python
>>> from scipy.signal import savgol_filter
>>> np.set_printoptions(precision=2)  # For compact display.
>>> x = np.array([2, 2, 5, 2, 1, 0, 1, 4, 9])
>>> savgol_filter(x, 5, 2)
array([ 1.66, 3.17, 3.54, 2.86, 0.66, 0.17, 1. , 4. , 9. ])
```

Filter with a window length of 5 and a degree 2 polynomial. Use the defaults for all other parameters.

```python
>>> savgol_filter(x, 5, 2)
array([ 1.66, 3.17, 3.54, 2.86, 0.66, 0.17, 1. , 4. , 9. ])
```

Note that the last five values in \( x \) are samples of a parabola, so when \( \text{mode} = \text{‘interp’} \) (the default) is used with \( \text{polyorder} = 2 \), the last three values are unchanged. Compare that to, for example, \( \text{mode} = \text{‘nearest’} \).
scipy.signal.deconvolve(signal, divisor)

Deconvolves divisor out of signal using inverse filtering.

Returns the quotient and remainder such that signal = convolve(divisor, quotient) + remainder

Parameters
- signal : array_like
  Signal data, typically a recorded signal
- divisor : array_like
  Divisor data, typically an impulse response or filter that was applied to the original signal

Returns
- quotient : ndarray
  Quotient, typically the recovered original signal
- remainder : ndarray
  Remainder

See also:
- numpy.polydiv
  performs polynomial division (same operation, but also accepts poly1d objects)

Examples
Deconvolve a signal that's been filtered:

```python
>>> from scipy import signal
>>> original = [0, 1, 0, 0, 1, 1, 0, 0]
>>> impulse_response = [2, 1]
>>> recorded = signal.convolve(impulse_response, original)
>>> recorded
array([0, 2, 1, 0, 2, 3, 1, 0, 0])
>>> recovered, remainder = signal.deconvolve(recorded, impulse_response)
>>> recovered
array([ 0., 1., 0., 0., 1., 1., 0., 0.])
```

scipy.signal.sosfilt(sos, x, axis=-1, zi=None)

Filter data along one dimension using cascaded second-order sections.

Filter a data sequence, x, using a digital IIR filter defined by sos. This is implemented by performing lfilter for each second-order section. See lfilter for details.

Parameters
- sos : array_like
  Array of second-order filter coefficients, must have shape (n_sections, 6). Each row corresponds to a second-order section, with the first three columns providing the numerator coefficients and the last three providing the denominator coefficients.
- x : array_like
  An N-dimensional input array.
- axis : int, optional
  The axis of the input data array along which to apply the linear filter. The filter is applied to each subarray along this axis. Default is -1.
- zi : array_like, optional
  Initial conditions for the cascaded filter delays. It is a (at least 2D) vector of shape (n_sections, ..., 2, ...), where ..., 2, ... denotes the shape of x, but with x.shape[axis] replaced by 2. If zi is None or is not given then initial rest (i.e. all zeros) is assumed. Note that...
Returns

- **y**: ndarray
  The output of the digital filter.
- **zf**: ndarray, optional
  If zi is None, this is not returned, otherwise, zf holds the final filter delay values.

See also:

- `zpk2sos`, `sos2zpk`, `sosfilt_zi`, `sosfiltfilt`, `sosfreqz`

Notes

The filter function is implemented as a series of second-order filters with direct-form II transposed structure. It is designed to minimize numerical precision errors for high-order filters.

New in version 0.16.0.

Examples

Plot a 13th-order filter’s impulse response using both `lfilter` and `sosfilt`, showing the instability that results from trying to do a 13th-order filter in a single stage (the numerical error pushes some poles outside of the unit circle):

```python
>>> import matplotlib.pyplot as plt
>>> from scipy import signal
>>> b, a = signal.ellip(13, 0.009, 80, 0.05, output='ba')
>>> sos = signal.ellip(13, 0.009, 80, 0.05, output='sos')
>>> x = signal.unit_impulse(700)
>>> y_tf = signal.lfilter(b, a, x)
>>> y_sos = signal.sosfilt(sos, x)
>>> plt.plot(y_tf, 'r', label='TF')
>>> plt.plot(y_sos, 'k', label='SOS')
>>> plt.legend(loc='best')
>>> plt.show()
```

![Graph showing impulse responses of TF and SOS filters](image)

scipy.signal.sosfilt_zi(sos)

Construct initial conditions for sosfilt for step response steady-state.
Compute an initial state $zi$ for the $sosfilt$ function that corresponds to the steady state of the step response. A typical use of this function is to set the initial state so that the output of the filter starts at the same value as the first element of the signal to be filtered.

**Parameters**

$sos : \text{array-like}$

Array of second-order filter coefficients, must have shape $(n\_sections, 6)$. See $sosfilt$ for the SOS filter format specification.

**Returns**

$zi : \text{ndarray}$

Initial conditions suitable for use with $sosfilt$, shape $(n\_sections, 2)$.

See also:

$sosfilt, zpk2sos$

Notes

New in version 0.16.0.

Examples

Filter a rectangular pulse that begins at time 0, with and without the use of the $zi$ argument of $\text{scipy.signal. sosfilt}$.

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> sos = signal.butter(9, 0.125, output='sos')
>>> zi = signal.sosfilt_zi(sos)
>>> x = (np.arange(250) < 100).astype(int)
>>> f1 = signal.sosfilt(sos, x)
>>> f2, zo = signal.sosfilt(sos, x, zi=zi)

>>> plt.plot(x, 'k--', label='x')
>>> plt.plot(f1, 'b', alpha=0.5, linewidth=2, label='filtered')
>>> plt.plot(f2, 'g', alpha=0.25, linewidth=4, label='filtered with zi')
>>> plt.legend(loc='best')
>>> plt.show()
```

5.20. Signal processing (scipy.signal) 1107
scipy.signal.sosfiltfilt (sos, x, axis=-1, padtype='odd', padlen=None)
A forward-backward digital filter using cascaded second-order sections.
See filtfilt for more complete information about this method.

Parameters

sos : array_like
    Array of second-order filter coefficients, must have shape
    (n_sections, 6). Each row corresponds to a second-order section, with
    the first three columns providing the numerator coefficients and the
    last three providing the denominator coefficients.

x : array_like
    The array of data to be filtered.

axis : int, optional
    The axis of x to which the filter is applied. Default is -1.

padtype : str or None, optional
    Must be 'odd', 'even', 'constant', or None. This determines the type
    of extension to use for the padded signal to which the filter is
    applied. If padtype is None, no padding is used. The default is 'odd'.

padlen : int or None, optional
    The number of elements by which to extend x at both ends of axis
    before applying the filter. This value must be less than x.shape[axis] - 1.
    padlen=0 implies no padding. The default value is:

    \[ 3 \times (2 \times \text{len}(sos) + 1 - \min((sos[:, 2] == 0).sum(),
    (sos[:, 5] == 0).sum())) \]

    The extra subtraction at the end attempts to compensate for poles and zeros
    at the origin (e.g. for odd-order filters) to yield equivalent estimates of
    padlen to those of filtfilt for second-order section filters built with
    scipy.signal functions.

Returns

y : ndarray
    The filtered output with the same shape as x.

See also:

filtfilt, sosfilt, sosfilt_zi, sosfreqz

Notes
New in version 0.18.0.

Examples

```python
>>> from scipy.signal import sosfiltfilt, butter
>>> import matplotlib.pyplot as plt
```
Create an interesting signal to filter.

```python
>>> n = 201
>>> t = np.linspace(0, 1, n)
>>> np.random.seed(123)
>>> x = 1 + (t < 0.5) - 0.25*t**2 + 0.05*np.random.randn(n)
```
Create a lowpass Butterworth filter, and use it to filter x.

```python
>>> sos = butter(4, 0.125, output='sos')
>>> y = sosfiltfilt(sos, x)
```
For comparison, apply an 8th order filter using `sosfilt`. The filter is initialized using the mean of the first four values of \( x \).

```python
>>> from scipy.signal import sosfilt, sosfilt_zi
>>> sos8 = butter(8, 0.125, output='sos')
>>> zi = x[:4].mean() * sosfilt_zi(sos8)
>>> y2, zo = sosfilt(sos8, x, zi=zi)
```

Plot the results. Note that the phase of \( y \) matches the input, while \( y2 \) has a significant phase delay.

```python
>>> plt.plot(t, x, alpha=0.5, label='x(t)')
>>> plt.plot(t, y, label='y(t)')
>>> plt.plot(t, y2, label='y2(t)')
>>> plt.legend(framealpha=1, shadow=True)
>>> plt.grid(alpha=0.25)
>>> plt.xlabel('t')
>>> plt.show()
```

### `scipy.signal.hilbert(x, N=None, axis=-1)`

Compute the analytic signal, using the Hilbert transform.

The transformation is done along the last axis by default.

- **Parameters**
  - `x` : array_like
    - Signal data. Must be real.
  - `N` : int, optional
    - Number of Fourier components. Default: \( x.shape[axis] \)
  - `axis` : int, optional
    - Axis along which to do the transformation. Default: -1.

- **Returns**
  - `xa` : ndarray
    - Axis along which to do the transformation. Default: -1.
    - Analytic signal of \( x \), of each 1-D array along \( axis \)

See also:

- `scipy.fftpack.hilbert`
  - Return Hilbert transform of a periodic sequence \( x \).
Notes

The analytic signal \( x_a(t) \) of signal \( x(t) \) is:

\[
x_a = F^{-1}(F(x)2U) = x + iy
\]

where \( F \) is the Fourier transform, \( U \) the unit step function, and \( y \) the Hilbert transform of \( x \). [R271]

In other words, the negative half of the frequency spectrum is zeroed out, turning the real-valued signal into a complex signal. The Hilbert transformed signal can be obtained from \( \text{np.imag(hilbert(x))} \), and the original signal from \( \text{np.real(hilbert(x))} \).

References

[R271], [R272], [R273]

Examples

In this example we use the Hilbert transform to determine the amplitude envelope and instantaneous frequency of an amplitude-modulated signal.

```python
>>> import numpy as np
>>> import matplotlib.pyplot as plt
>>> from scipy.signal import hilbert, chirp

>>> duration = 1.0
>>> fs = 400.0
>>> samples = int(fs*duration)
>>> t = np.arange(samples) / fs

We create a chirp of which the frequency increases from 20 Hz to 100 Hz and apply an amplitude modulation.

```python
>>> signal = chirp(t, 20.0, t[-1], 100.0)
>>> signal *= (1.0 + 0.5 * np.sin(2.0*np.pi*3.0*t) )
```

The amplitude envelope is given by magnitude of the analytic signal. The instantaneous frequency can be obtained by differentiating the instantaneous phase in respect to time. The instantaneous phase corresponds to the phase angle of the analytic signal.

```python
>>> analytic_signal = hilbert(signal)
>>> amplitude_envelope = np.abs(analytic_signal)
>>> instantaneous_phase = np.unwrap(np.angle(analytic_signal))
>>> instantaneous_frequency = (np.diff(instantaneous_phase) / (2.0*np.pi)) * fs
```

```python
>>> fig = plt.figure()
>>> ax0 = fig.add_subplot(211)
>>> ax0.plot(t, signal, label='signal')
>>> ax0.plot(t, amplitude_envelope, label='envelope')
>>> ax0.set_xlabel("time in seconds")
>>> ax0.legend()

>>> ax1 = fig.add_subplot(212)
>>> ax1.plot(t[1:], instantaneous_frequency)
>>> ax1.set_xlabel("time in seconds")
>>> ax1.set_ylim(0.0, 120.0)
```
scipy.signal.hilbert2(x, N=None)
Compute the ‘2-D’ analytic signal of x

Parameters
x : array_like
   2-D signal data.
N : int or tuple of two ints, optional
   Number of Fourier components. Default is x.shape

Returns
xa : ndarray
   Analytic signal of x taken along axes (0,1).

References
[R274]

scipy.signal.decimate(x, q, n=None, ftype='iir', axis=-1, zero_phase=True)
Downsample the signal after applying an anti-aliasing filter.

By default, an order 8 Chebyshev type I filter is used. A 30 point FIR filter with Hamming window is used if ftype is ‘fir’.

Parameters
x : array_like
   The signal to be downsampled, as an N-dimensional array.
q : int
   The downsampling factor. When using IIR downsampling, it is recommended to call decimate multiple times for downsampling factors higher than 13.
n : int, optional
   The order of the filter (1 less than the length for ‘fir’). Defaults to 8 for ‘iir’ and 20 times the downsampling factor for ‘fir’.
ftype : str {'iir', 'fir'} or dlti instance, optional
   If ‘iir’ or ‘fir’, specifies the type of lowpass filter. If an instance of an dlti object, uses that object to filter before downsampling.
axis : int, optional
   The axis along which to decimate.
zero_phase : bool, optional
   Prevent phase shift by filtering with filtfilt instead of lfilter when using an IIR filter, and shifting the outputs back by the filter’s group delay.

5.20. Signal processing (scipy.signal)
when using an FIR filter. The default value of True is recommended, since
a phase shift is generally not desired.

Returns  

\[ y : \text{ndarray} \]

\[ \text{The down-sampled signal.} \]

See also:

resample  
Resample up or down using the FFT method.
resample_poly  
Resample using polyphase filtering and an FIR filter.

Notes

The zero_phase keyword was added in 0.18.0. The possibility to use instances of dlti as ftype was added in 0.18.0.

```
scipy.signal.detrend(data, axis=-1, type='linear', bp=0)
```

Remove linear trend along axis from data.

Parameters  

\[ \text{data : array_like} \]

\[ \text{The input data.} \]

\[ \text{axis : int, optional} \]

\[ \text{The axis along which to detrend the data. By default this is the last axis (-1).} \]

\[ \text{type : \{'linear', 'constant'\}, optional} \]

\[ \text{The type of detrending. If type == 'linear' (default), the result of a linear least-squares fit to data is subtracted from data. If type == 'constant', only the mean of data is subtracted.} \]

\[ \text{bp : array_like of ints, optional} \]

\[ \text{A sequence of break points. If given, an individual linear fit is performed for each part of data between two break points. Break points are specified as indices into data.} \]

Returns  

\[ \text{ret : ndarray} \]

\[ \text{The detrended input data.} \]

Examples

```
>>> from scipy import signal
>>> randgen = np.random.RandomState(9)
>>> npoints = 1000
>>> noise = randgen.randn(npoints)
>>> x = 3 + 2*np.linspace(0, 1, npoints) + noise
>>> (signal.detrend(x) - noise).max() < 0.01
True
```

```
scipy.signal.resample(x, num, t=None, axis=0, window=None)
```

Resample x to num samples using Fourier method along the given axis.

The resampled signal starts at the same value as x but is sampled with a spacing of len(x) / num * (spacing of x). Because a Fourier method is used, the signal is assumed to be periodic.

Parameters  

\[ \text{x : array_like} \]

\[ \text{The data to be resampled.} \]

\[ \text{num : int} \]

\[ \text{The number of samples in the resampled signal.} \]

\[ \text{t : array_like, optional} \]

\[ \text{If t is given, it is assumed to be the sample positions associated with the signal data in x.} \]
**axis** : int, optional
The axis of \( x \) that is resampled. Default is 0.

**window** : array_like, callable, string, float, or tuple, optional
Specifies the window applied to the signal in the Fourier domain. See below for details.

**Returns**
resampled_x or (resampled_x, resampled_t)
Either the resampled array, or, if \( t \) was given, a tuple containing the resampled array and the corresponding resampled positions.

See also:
- **decimate**  
  Downsample the signal after applying an FIR or IIR filter.
- **resample_poly**  
  Resample using polyphase filtering and an FIR filter.

**Notes**
The argument \( window \) controls a Fourier-domain window that tapers the Fourier spectrum before zero-padding to alleviate ringing in the resampled values for sampled signals you didn’t intend to be interpreted as band-limited.

If \( window \) is a function, then it is called with a vector of inputs indicating the frequency bins (i.e. \( \text{fft freq}(x.\text{shape}[\text{axis}]) \)).

If \( window \) is an array of the same length as \( x.\text{shape}[\text{axis}] \) it is assumed to be the window to be applied directly in the Fourier domain (with dc and low-frequency first).

For any other type of \( window \), the function \( \text{scipy.signal.get_window} \) is called to generate the window.

The first sample of the returned vector is the same as the first sample of the input vector. The spacing between samples is changed from \( dx \) to \( dx * \frac{\text{len}(x)}{\text{num}} \).

If \( t \) is not None, then it represents the old sample positions, and the new sample positions will be returned as well as the new samples.

As noted, **resample** uses FFT transformations, which can be very slow if the number of input or output samples is large and prime; see **scipy.fft**.

**Examples**
Note that the end of the resampled data rises to meet the first sample of the next cycle:

```python
>>> from scipy import signal

>>> x = np.linspace(0, 10, 20, endpoint=False)
>>> y = np.cos(-x**2/6.0)
>>> f = signal.resample(y, 100)
>>> xnew = np.linspace(0, 10, 100, endpoint=False)

>>> import matplotlib.pyplot as plt
>>> plt.plot(x, y, 'go-', xnew, f, '.-', 10, y[0], 'ro')
>>> plt.legend(['data', 'resampled'], loc='best')
>>> plt.show()
```
scipy.signal.resample_poly(x, up, down, axis=0, window=('kaiser', 5.0))

Resample x along the given axis using polyphase filtering.

The signal x is upsampled by the factor up, a zero-phase low-pass FIR filter is applied, and then it is downsampled by the factor down. The resulting sample rate is \( \frac{\text{up}}{\text{down}} \) times the original sample rate. Values beyond the boundary of the signal are assumed to be zero during the filtering step.

**Parameters**

- **x**: array_like
  The data to be resampled.
- **up**: int
  The upsampling factor.
- **down**: int
  The downsampling factor.
- **axis**: int, optional
  The axis of x that is resampled. Default is 0.
- **window**: string, tuple, or array_like, optional
  Desired window to use to design the low-pass filter, or the FIR filter coefficients to employ. See below for details.

**Returns**

- **resampled_x**: array
  The resampled array.

**See also:**

decimate  Downsample the signal after applying an FIR or IIR filter.
resample  Resample up or down using the FFT method.

**Notes**

This polyphase method will likely be faster than the Fourier method in scipy.signal.resample when the number of samples is large and prime, or when the number of samples is large and up and down share a large greatest common denominator. The length of the FIR filter used will depend on \( \text{max}(\text{up}, \text{down}) / \text{gcd}(\text{up}, \text{down}) \), and the number of operations during polyphase filtering will depend on the filter length and down (see scipy.signal.upfirdn for details).

The argument window specifies the FIR low-pass filter design.

If window is an array_like it is assumed to be the FIR filter coefficients. Note that the FIR filter is applied after the upsampling step, so it should be designed to operate on a signal at a sampling frequency higher than the original by a factor of \( \text{up} / \text{gcd}(\text{up}, \text{down}) \). This function’s output will be centered with respect to this array, so it
is best to pass a symmetric filter with an odd number of samples if, as is usually the case, a zero-phase filter is desired.

For any other type of window, the functions `scipy.signal.get_window` and `scipy.signal.firwin` are called to generate the appropriate filter coefficients.

The first sample of the returned vector is the same as the first sample of the input vector. The spacing between samples is changed from $\delta x$ to $\delta x \times \text{down} / \text{float}(\text{up})$.

**Examples**

Note that the end of the resampled data rises to meet the first sample of the next cycle for the FFT method, and gets closer to zero for the polyphase method:

```python
>>> from scipy import signal

## Examples

```python
>>> x = np.linspace(0, 10, 20, endpoint=False)
>>> y = np.cos(-x**2/6.0)
>>> f_fft = signal.resample(y, 100)
>>> f_poly = signal.resample_poly(y, 100, 20)
>>> xnew = np.linspace(0, 10, 100, endpoint=False)
>>> import matplotlib.pyplot as plt
>>> plt.plot(xnew, f_fft, 'b.-', xnew, f_poly, 'r.-')
>>> plt.plot(x, y, 'ko-')
>>> plt.plot(10, y[0], 'bo', 10, 0., 'ro')  # boundaries
>>> plt.legend(['resample', 'resamp_poly', 'data'], loc='best')
>>> plt.show()
```

```python
>>> x = np.linspace(0, 10, 20, endpoint=False)
>>> y = np.cos(-x**2/6.0)
>>> f_fft = signal.resample(y, 100)
>>> f_poly = signal.resample_poly(y, 100, 20)
>>> xnew = np.linspace(0, 10, 100, endpoint=False)
>>> import matplotlib.pyplot as plt
>>> plt.plot(xnew, f_fft, 'b.-', xnew, f_poly, 'r.-')
>>> plt.plot(x, y, 'ko-')
>>> plt.plot(10, y[0], 'bo', 10, 0., 'ro')  # boundaries
>>> plt.legend(['resample', 'resamp_poly', 'data'], loc='best')
>>> plt.show()
```

scipy.signal.upfirdn($h$, $x$, up=1, down=1, axis=-1)

Upsample, FIR filter, and downsample

**Parameters**

- **$h$**: array_like
  1-dimensional FIR (finite-impulse response) filter coefficients.
- **$x$**: array_like
  Input signal array.
- **up**: int, optional
  Upsampling rate. Default is 1.
down : int, optional
Downsampling rate. Default is 1.

axis : int, optional
The axis of the input data array along which to apply the linear filter. The
filter is applied to each subarray along this axis. Default is -1.

Returns y : ndarray
The output signal array. Dimensions will be the same as x except for along
axis, which will change size according to the h, up, and down parameters.

Notes
The algorithm is an implementation of the block diagram shown on page 129 of the Vaidyanathan text [R305]
(Figure 4.3-8d).

The direct approach of upsampling by factor of P with zero insertion, FIR filtering of length N, and downsam-
pling by factor of Q is O(N*Q) per output sample. The polyphase implementation used here is O(N/P).

New in version 0.18.

Examples
Simple operations:

```python
>>> from scipy.signal import upfirdn
>>> upfirdn([1, 1, 1], [1, 1, 1])  # FIR filter
array([ 1., 2., 3., 2., 1.])
>>> upfirdn([1], [1, 2, 3], 3)  # upsampling with zeros insertion
array([ 1., 0., 0., 2., 0., 0., 3., 0., 0.])
>>> upfirdn([1, 1, 1], [1, 2, 3], 3)  # upsampling with sample-and-hold
array([ 1., 1., 2., 2., 2., 3.])
>>> upfirdn([.5, 1., .5], [1, 1, 1], 2)  # linear interpolation
array([ 1., 1., 1., 1.])
>>> upfirdn([1], np.arange(10), 1, 3)  # decimation by 3
array([ 0., 3., 6., 9.])
>>> upfirdn([.5, 1, .5], np.arange(10), 2, 3)  # linear interp, rate 2/3
array([ 0. , 1. , 2.5, 4. , 5.5, 7. , 8.5, 0. ])
```

Apply a single filter to multiple signals:

```python
>>> x = np.reshape(np.arange(8), (4, 2))
>>> x
array([[0, 1],
       [2, 3],
       [4, 5],
       [6, 7]])
```

Apply along the last dimension of x:

```python
>>> h = [1, 1]
>>> upfirdn(h, x, 2)
array([[ 0., 1., 1., 1.],
       [ 2., 2., 3., 3.],
       [ 4., 4., 5., 5.],
       [ 6., 6., 7., 7.]])
```

Apply along the 0th dimension of x:

```python
>>> upfirdn(h, x, 2, axis=0)
array([[ 0., 1.],
       [ 0., 1.]])
```

`scipy.signal.bilinear(b, a, fs=1.0)`

Return a digital filter from an analog one using a bilinear transform.

The bilinear transform substitutes \((z-1) / (z+1)\) for \(s\).

`scipy.signal.findfreqs(num, den, N, kind='ba')`
Find array of frequencies for computing the response of an analog filter.

**Parameters**

- `num, den`: array_like, 1-D
  The polynomial coefficients of the numerator and denominator of the transfer function of the filter or LTI system, where the coefficients are ordered from highest to lowest degree. Or, the roots of the transfer function numerator and denominator (i.e. zeroes and poles).

- `N`: int
  The length of the array to be computed.

- `kind`: str {'ba', 'zp'}, optional
  Specifies whether the numerator and denominator are specified by their polynomial coefficients ('ba'), or their roots ('zp').

**Returns**

- `w`: (N,) ndarray
  A 1-D array of frequencies, logarithmically spaced.

**Examples**

Find a set of nine frequencies that span the “interesting part” of the frequency response for the filter with the transfer function

\[ H(s) = \frac{s}{s^2 + 8s + 25} \]

```python
>>> from scipy import signal
>>> signal.findfreqs([1, 0], [1, 8, 25], N=9)
array([ 1.00000000e-02, 3.16227766e-02, 1.00000000e-01, 3.16227766e-01, 1.00000000e+00, 3.16227766e+00, 1.00000000e+01, 3.16227766e+01, 1.00000000e+02])
```

**scipy.signal.firls(numtaps, bands, desired, weight=None, nyq=None, fs=None)**

FIR filter design using least-squares error minimization.

Calculate the filter coefficients for the linear-phase finite impulse response (FIR) filter which has the best approximation to the desired frequency response described by `bands` and `desired` in the least squares sense (i.e., the integral of the weighted mean-squared error within the specified bands is minimized).

**Parameters**

- `numtaps`: int
  The number of taps in the FIR filter. `numtaps` must be odd.

- `bands`: array_like
  A monotonic nondecreasing sequence containing the band edges in Hz. All elements must be non-negative and less than or equal to the Nyquist frequency given by `nyq`.

- `desired`: array_like
  A sequence the same size as `bands` containing the desired gain at the start and end point of each band.

- `weight`: array_like, optional
  A relative weighting to give to each band region when solving the least squares problem. `weight` has to be half the size of `bands`.

- `nyq`: float, optional
  Deprecated. Use ‘fs’ instead. Nyquist frequency. Each frequency in `bands` must be between 0 and `nyq` (inclusive). Default is 1.

- `fs`: float, optional
  The sampling frequency of the signal. Each frequency in `bands` must be between 0 and `fs/2` (inclusive). Default is 2.

**Returns**

- `coeffs`: ndarray
  Coefficients of the optimal (in a least squares sense) FIR filter.

**See also:**

`firwin`, `firwin2`, `minimum_phase`, `remez`
Notes

This implementation follows the algorithm given in [R254]. As noted there, least squares design has multiple advantages:

1. Optimal in a least-squares sense.
2. Simple, non-iterative method.
3. The general solution can be obtained by solving a linear system of equations.
4. Allows the use of a frequency dependent weighting function.

This function constructs a Type I linear phase FIR filter, which contains an odd number of coeffs satisfying for \( n < \text{numtaps} \):

\[
\text{coeffs}(n) = \text{coeffs}(\text{numtaps} - 1 - n)
\]

The odd number of coefficients and filter symmetry avoid boundary conditions that could otherwise occur at the Nyquist and 0 frequencies (e.g., for Type II, III, or IV variants).

New in version 0.18.

References

[R254]

Examples

We want to construct a band-pass filter. Note that the behavior in the frequency ranges between our stop bands and pass bands is unspecified, and thus may overshoot depending on the parameters of our filter:

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> fig, axs = plt.subplots(2)
>>> fs = 10.0  # Hz
>>> desired = (0, 0, 1, 1, 0, 0)
>>> for bi, bands in enumerate(((0, 1, 2, 3, 4, 5), (0, 1, 2, 4, 4.5, 5))):
...     fir_firls = signal.firls(73, bands, desired, fs=fs)
...     fir_remez = signal.remez(73, bands, desired[::-2], fs=fs)
...     fir_firwin2 = signal.firwin2(73, bands, desired, fs=fs)
...     hs = list()
...     ax = axs[bi]
...     for fir in (fir_firls, fir_remez, fir_firwin2):
...         freq, response = signal.freqz(fir)
...         hs.append(ax.semilogy(0.5*fs*freq/np.pi, np.abs(response))[0])
...     for band, gains in zip(zip(bands[::-2], bands[1::2]),
...                           zip(desired[::-2], desired[1::2])):
...         ax.semilogy(band, np.maximum(gains, 1e-7), 'k--', linewidth=2)
...     if bi == 0:
...         ax.legend(hs, ('firls', 'remez', 'firwin2'),
...                  loc='lower center', frameon=False)
...     else:
...         ax.set_xlabel('Frequency (Hz)')
...         ax.grid(True)
...         ax.set(title='Band-pass %d-%d Hz' % bands[2:4], ylabel='Magnitude')
...     if bi == 0:
...         ax.legend(hs, ('firls', 'remez', 'firwin2'),
...                  loc='lower center', frameon=False)
...     else:
...         ax.grid(True)
...         ax.set(title='Band-pass %d-%d Hz' % bands[2:4], ylabel='Magnitude')
>>> fig.tight_layout()
>>> plt.show()
```
scipy.signal.firwin(numtaps, cutoff, width=None, window='hamming', pass_zero=True, scale=True, nyq=None, fs=None)

FIR filter design using the window method.

This function computes the coefficients of a finite impulse response filter. The filter will have linear phase; it will be Type I if `numtaps` is odd and Type II if `numtaps` is even.

Type II filters always have zero response at the Nyquist frequency, so a ValueError exception is raised if firwin is called with `numtaps` even and having a passband whose right end is at the Nyquist frequency.

Parameters

- **numtaps** : int
  Length of the filter (number of coefficients, i.e. the filter order + 1). `numtaps` must be even if a passband includes the Nyquist frequency.

- **cutoff** : float or 1D array_like
  Cutoff frequency of filter (expressed in the same units as `nyq`) OR an array of cutoff frequencies (that is, band edges). In the latter case, the frequencies in `cutoff` should be positive and monotonically increasing between 0 and `nyq`. The values 0 and `nyq` must not be included in `cutoff`.

- **width** : float or None, optional
  If `width` is not None, then assume it is the approximate width of the transition region (expressed in the same units as `nyq`) for use in Kaiser FIR filter design. In this case, the `window` argument is ignored.

- **window** : string or tuple of string and parameter values, optional
  Desired window to use. See `scipy.signal.get_window` for a list of windows and required parameters.

- **pass_zero** : bool, optional
  If True, the gain at the frequency 0 (i.e. the “DC gain”) is 1. Otherwise the DC gain is 0.

- **scale** : bool, optional
  Set to True to scale the coefficients so that the frequency response is exactly unity at a certain frequency. That frequency is either:
  - 0 (DC) if the first passband starts at 0 (i.e. `pass_zero` is True)
  - `nyq` (the Nyquist frequency) if the first passband ends at `nyq`
  (i.e the filter is a single band highpass filter); center of first passband otherwise

- **nyq** : float, optional
**SciPy Reference Guide, Release 1.0.0**

**deprecated. Use 'fs' instead.** This is the Nyquist frequency. Each frequency in `cutoff` must be between 0 and `nyq`. Default is 1.

**Parameter**

`fs`: float, optional

The sampling frequency of the signal. Each frequency in `cutoff` must be between 0 and `fs/2`. Default is 2.

**Returns**

`h`: (numtaps,) ndarray

Coefficients of length `numtaps` FIR filter.

**Raises**

`ValueError`

If any value in `cutoff` is less than or equal to 0 or greater than or equal to `fs/2`, if the values in `cutoff` are not strictly monotonically increasing, or if `numtaps` is even but a passband includes the Nyquist frequency.

**See also:**

`firwin2`, `firls`, `minimum_phase`, `remez`

**Examples**

Low-pass from 0 to f:

```python
>>> from scipy import signal
>>> numtaps = 3
>>> f = 0.1
>>> signal.firwin(numtaps, f)
array([ 0.06799017, 0.86401967, 0.06799017])
```

Use a specific window function:

```python
>>> signal.firwin(numtaps, f, window='nuttall')
array([ 3.56607041e-04, 9.99286786e-01, 3.56607041e-04])
```

High-pass ('stop' from 0 to f):

```python
>>> signal.firwin(numtaps, f, pass_zero=False)
array([-0.00859313, 0.98281375, -0.00859313])
```

Band-pass:

```python
>>> f1, f2 = 0.1, 0.2
>>> signal.firwin(numtaps, [f1, f2], pass_zero=False)
array([ 0.06301614, 0.88770441, 0.06301614])
```

Band-stop:

```python
>>> signal.firwin(numtaps, [f1, f2])
array([-0.00801395, 1.0160279 , -0.00801395])
```

Multi-band (passbands are [0, f1], [f2, f3] and [f4, 1]):

```python
>>> f3, f4 = 0.3, 0.4
>>> signal.firwin(numtaps, [f1, f2, f3, f4])
array([-0.01376344, 1.02752689, -0.01376344])
```

Multi-band (passbands are [f1, f2] and [f3,f4]):

```python
>>> signal.firwin(numtaps, [f1, f2, f3, f4], pass_zero=False)
array([ 0.04890915, 0.91284326, 0.04890915])
```
**scipy.signal.firwin2**

FIR filter design using the window method.

From the given frequencies `freq` and corresponding gains `gain`, this function constructs an FIR filter with linear phase and (approximately) the given frequency response.

**Parameters**

- `numtaps` : int
  The number of taps in the FIR filter. `numtaps` must be less than `nfreqs`.

- `freq` : array_like, 1D
  The frequency sampling points. Typically 0.0 to 1.0 with 1.0 being Nyquist. The Nyquist frequency is half `fs`. The values in `freq` must be nondecreasing. A value can be repeated once to implement a discontinuity. The first value in `freq` must be 0, and the last value must be `fs/2`.

- `gain` : array_like
  The filter gains at the frequency sampling points. Certain constraints to gain values, depending on the filter type, are applied, see Notes for details.

- `nfreqs` : int, optional
  The size of the interpolation mesh used to construct the filter. For most efficient behavior, this should be a power of 2 plus 1 (e.g., 129, 257, etc). The default is one more than the smallest power of 2 that is not less than `numtaps`. `nfreqs` must be greater than `numtaps`.

- `window` : string or (string, float) or float, or None, optional
  Window function to use. Default is “hamming”. See `scipy.signal.get_window` for the complete list of possible values. If None, no window function is applied.

- `nyq` : float, optional
  Deprecated. Use ‘fs’ instead. This is the Nyquist frequency. Each frequency in `freq` must be between 0 and `nyq`. Default is 1.

- `antisymmetric` : bool, optional
  Whether resulting impulse response is symmetric/antisymmetric. See Notes for more details.

- `fs` : float, optional
  The sampling frequency of the signal. Each frequency in `cutoff` must be between 0 and `fs/2`. Default is 2.

**Returns**

- `taps` : ndarray
  The filter coefficients of the FIR filter, as a 1-D array of length `numtaps`.

**Notes**

From the given set of frequencies and gains, the desired response is constructed in the frequency domain. The inverse FFT is applied to the desired response to create the associated convolution kernel, and the first `numtaps` coefficients of this kernel, scaled by `window`, are returned.

The FIR filter will have linear phase. The type of filter is determined by the value of ‘numtaps’ and `antisymmetric` flag. There are four possible combinations:

- odd `numtaps`, `antisymmetric` is False, type I filter is produced
- even `numtaps`, `antisymmetric` is False, type II filter is produced
- odd `numtaps`, `antisymmetric` is True, type III filter is produced
- even `numtaps`, `antisymmetric` is True, type IV filter is produced

Magnitude response of all but type I filters are subjects to following constraints:

- type II – zero at the Nyquist frequency
- type III – zero at zero and Nyquist frequencies
- type IV – zero at zero frequency

**See also:**

`firls`, `firwin`, `minimum_phase`, `remez`
New in version 0.9.0.

References
[R255], [R256]

Examples
A lowpass FIR filter with a response that is 1 on [0.0, 0.5], and that decreases linearly on [0.5, 1.0] from 1 to 0:

```python
>>> from scipy import signal
>>> taps = signal.firwin2(150, [0.0, 0.5, 1.0], [1.0, 1.0, 0.0])
>>> print(taps[72:78])
[-0.02286961 -0.06362756 0.57310236 0.57310236 -0.06362756 -0.02286961]
```

```
scipy.signal.freqs(b, a, worN=None, plot=None)
```

Compute frequency response of analog filter.

Given the M-order numerator \(b\) and N-order denominator \(a\) of an analog filter, compute its frequency response:

\[
H(w) = \frac{b[0] \times (jw)^M + b[1] \times (jw)^{(M-1)} + \ldots + b[M]}{a[0] \times (jw)^N + a[1] \times (jw)^{(N-1)} + \ldots + a[N]}
\]

**Parameters**
- \(b\): array_like
  Numerator of a linear filter.
- \(a\): array_like
  Denominator of a linear filter.
- \(worN\): {None, int, array_like}, optional
  If None, then compute at 200 frequencies around the interesting parts of the response curve (determined by pole-zero locations). If a single integer, then compute at that many frequencies. Otherwise, compute the response at the angular frequencies (e.g. rad/s) given in \(worN\).
- \(plot\): callable, optional
  A callable that takes two arguments. If given, the return parameters \(w\) and \(h\) are passed to plot. Useful for plotting the frequency response inside `freqs`.

**Returns**
- \(w\): ndarray
  The angular frequencies at which \(h\) was computed.
- \(h\): ndarray
  The frequency response.

See also:
- `freqz`
  Compute the frequency response of a digital filter.

**Notes**
Using Matplotlib’s “plot” function as the callable for \(plot\) produces unexpected results, this plots the real part of the complex transfer function, not the magnitude. Try `lambda w, h: plot(w, abs(h))`.

**Examples**

```python
>>> from scipy.signal import freqs, iirfilter

>>> b, a = iirfilter(4, [1, 10], 1, 60, analog=True, ftype='cheby1')

>>> w, h = freqs(b, a, worN=np.logspace(-1, 2, 1000))
```

5.20. Signal processing (`scipy.signal`) 1123
```python
>>> import matplotlib.pyplot as plt
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.xlabel('Frequency')
>>> plt.ylabel('Amplitude response [dB]')
>>> plt.grid()
>>> plt.show()
```

![Amplitude response graph](image)

```python
scipy.signal.freqs_zpk(z, p, k, worN=None)
```

Computes the frequency response of an analog filter.

Given the zeros `z`, poles `p`, and gain `k` of a filter, compute its frequency response:

\[
H(w) = k \frac{(jw-z[0]) \times (jw-z[1]) \times \ldots \times (jw-z[-1])}{(jw-p[0]) \times (jw-p[1]) \times \ldots \times (jw-p[-1])}
\]

**Parameters**
- `z`: array_like
  - Zeros of a linear filter
- `p`: array_like
  - Poles of a linear filter
- `k`: scalar
  - Gain of a linear filter
- `worN`: {None, int, array_like}, optional
  - If None, then compute at 200 frequencies around the interesting parts of the response curve (determined by pole-zero locations). If a single integer, then compute at that many frequencies. Otherwise, compute the response at the angular frequencies (e.g. rad/s) given in `worN`.

**Returns**
- `w`: ndarray
  - The angular frequencies at which `h` was computed.
- `h`: ndarray
  - The frequency response.

**See also:**
- `freqs`:
  - Compute the frequency response of an analog filter in TF form
- `freqz`:
  - Compute the frequency response of a digital filter in TF form
- `freqz_zpk`:
  - Compute the frequency response of a digital filter in ZPK form
Notes

Examples

```python
>>> from scipy.signal import freqs_zpk, iirfilter

>>> z, p, k = iirfilter(4, [1, 10], 1, 60, analog=True, ftype='cheby1',
                        output='zpk')

>>> w, h = freqs_zpk(z, p, k, worN=np.logspace(-1, 2, 1000))

>>> import matplotlib.pyplot as plt

>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.xlabel('Frequency')
>>> plt.ylabel('Amplitude response [dB]')
>>> plt.grid()
>>> plt.show()
```

scipy.signal.freqz(b, a=1, worN=None, whole=False, plot=None)

Compute the frequency response of a digital filter.

Given the M-order numerator \(b\) and N-order denominator \(a\) of a digital filter, compute its frequency response:

\[
H(e^{j\omega}) = \frac{b[0] + b[1]e^{-j\omega} + \cdots + b[M]e^{-jM\omega}}{a[0] + a[1]e^{-j\omega} + \cdots + a[N]e^{-jN\omega}}
\]

Parameters

- **b**: array_like
  Numerator of a linear filter. If \(b\) has dimension greater than 1, it is assumed that the coefficients are stored in the first dimension, and \(b.shape[1:]\), \(a.shape[1:]\), and the shape of the frequencies array must be compatible for broadcasting.

- **a**: array_like
Denominator of a linear filter. If $b$ has dimension greater than 1, it is assumed that the coefficients are stored in the first dimension, and $b$.shape[1:], $a$.shape[1:], and the shape of the frequencies array must be compatible for broadcasting.

$\text{worN} : \{\text{None, int, array_like}\}$, optional
If None (default), then compute at 512 equally spaced frequencies. If a single integer, then compute at that many frequencies. This is a convenient alternative to:

```python
np.linspace(0, 2*pi if whole else pi, N,
endpoint=False)
```

Using a number that is fast for FFT computations can result in faster computations (see Notes). If an array_like, compute the response at the frequencies given (in radians/sample).

$\text{whole} : \text{bool}$, optional
Normally, frequencies are computed from 0 to the Nyquist frequency, pi radians/sample (upper-half of unit-circle). If whole is True, compute frequencies from 0 to 2*pi radians/sample.

$\text{plot} : \text{callable}$
A callable that takes two arguments. If given, the return parameters $w$ and $h$ are passed to plot. Useful for plotting the frequency response inside freqz.

$\text{Returns}$

- $w : \text{ndarray}$
The normalized frequencies at which $h$ was computed, in radians/sample.
- $h : \text{ndarray}$
The frequency response, as complex numbers.

$\text{See also:}$

freqz_zpk, sosfreqz

$\text{Notes}$

Using Matplotlib’s matplotlib.pyplot.plot function as the callable for plot produces unexpected results, as this plots the real part of the complex transfer function, not the magnitude. Try lambda $w$, $h$: plot($w$, np.abs($h$)).

A direct computation via (R)FFT is used to compute the frequency response when the following conditions are met:

1. An integer value is given for $\text{worN}$.
2. $\text{worN}$ is fast to compute via FFT (i.e., next_fast_len($\text{worN}$) equals $\text{worN}$).
3. The denominator coefficients are a single value ($a$.shape[0] == 1).
4. $\text{worN}$ is at least as long as the numerator coefficients ($\text{worN} >= b$.shape[0]).
5. If $b$.ndim > 1, then $b$.shape[-1] == 1.

For long FIR filters, the FFT approach can have lower error and be much faster than the equivalent direct polynomial calculation.

$\text{Examples}$

```python
>>> from scipy import signal
>>> b = signal.firwin(80, 0.5, window=('kaiser', 8))
>>> w, h = signal.freqz(b)

>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> plt.title('Digital filter frequency response')
>>> ax1 = fig.add_subplot(111)
```
>>> plt.plot(w, 20 * np.log10(abs(h)), 'b')
>>> plt.ylabel('Amplitude [dB]', color='b')
>>> plt.xlabel('Frequency [rad/sample]')

>>> ax2 = ax1.twinx()
>>> angles = np.unwrap(np.angle(h))
>>> plt.plot(w, angles, 'g')
>>> plt.ylabel('Angle (radians)', color='g')
>>> plt.grid()
>>> plt.axis('tight')
>>> plt.show()

Broadcasting Examples

Suppose we have two FIR filters whose coefficients are stored in the rows of an array with shape (2, 25). For this demonstration we'll use random data:

```python
>>> np.random.seed(42)
>>> b = np.random.rand(2, 25)
```

To compute the frequency response for these two filters with one call to `freqz`, we must pass in `b.T`, because `freqz` expects the first axis to hold the coefficients. We must then extend the shape with a trivial dimension of length 1 to allow broadcasting with the array of frequencies. That is, we pass in `b.T[..., np.newaxis]`, which has shape (25, 2, 1):

```python
>>> w, h = signal.freqz(b.T[..., np.newaxis], worN=1024)
```

Now suppose we have two transfer functions, with the same numerator coefficients `b = [0.5, 0.5]`. The coefficients for the two denominators are stored in the first dimension of the two-dimensional array `a`:

```python
a = [[1, 1]
     [-0.25, -0.5]]
```
```python
>>> b = np.array([0.5, 0.5])
>>> a = np.array([[1, 1], [-0.25, -0.5]])
```

Only `a` is more than one-dimensional. To make it compatible for broadcasting with the frequencies, we extend it with a trivial dimension in the call to `freqz`:

```python
>>> w, h = signal.freqz(b, a[..., np.newaxis], worN=1024)
>>> w.shape
(1024,)
>>> h.shape
(2, 1024)
```

`scipy.signal.freqz_zpk(z, p, k, worN=None, whole=False)`

Compute the frequency response of a digital filter in ZPK form.

Given the Zeros, Poles and Gain of a digital filter, compute its frequency response:  

\[
H(z) = k \prod_i (z - Z[i]) / \prod_j (z - P[j])
\]

where \(k\) is the gain, \(Z\) are the zeros and \(P\) are the poles.

**Parameters**
- `z`: array_like  
  Zeroes of a linear filter
- `p`: array_like  
  Poles of a linear filter
- `k`: scalar  
  Gain of a linear filter
- `worN`: {None, int, array_like}, optional  
  If single integer (default 512, same as None), then compute at `worN` frequencies equally spaced around the unit circle. If an array_like, compute the response at the frequencies given (in radians/sample).
- `whole`: bool, optional  
  Normally, frequencies are computed from 0 to the Nyquist frequency, \(\pi\) radians/sample (upper-half of unit-circle). If `whole` is True, compute frequencies from 0 to \(2\pi\) radians/sample.

**Returns**
- `w`: ndarray  
  The normalized frequencies at which \(h\) was computed, in radians/sample.
- `h`: ndarray  
  The frequency response.

**See also:**
- `freqs`  
  Compute the frequency response of an analog filter in TF form
- `freqs_zpk`  
  Compute the frequency response of an analog filter in ZPK form
- `freqz`  
  Compute the frequency response of a digital filter in TF form

**Notes**

**Examples**

```python
>>> from scipy import signal
>>> z, p, k = signal.butter(4, 0.2, output='zpk')
>>> w, h = signal.freqz_zpk(z, p, k)
```
```python
>>> plt.plot(w, 20 * np.log10(abs(h)), 'b')
>>> plt.ylabel('Amplitude [dB]', color='b')
>>> plt.xlabel('Frequency [rad/sample]')

>>> ax2 = ax1.twinx()
>>> angles = np.unwrap(np.angle(h))
>>> plt.plot(w, angles, 'g')
>>> plt.ylabel('Angle (radians)', color='g')
>>> plt.grid()
>>> plt.axis('tight')
>>> plt.show()
```

scipy.signal.sosfreqz(sos, worN=None, whole=False)

Compute the frequency response of a digital filter in SOS format.

Given `sos`, an array with shape (n, 6) of second order sections of a digital filter, compute the frequency response of the system function:

\[
H(z) = \frac{B0(z) B1(z) ... B{n-1}(z)}{A0(z) A1(z) ... A{n-1}(z)}
\]

for \(z = \exp(\omega*1j)\), where \(B{k}(z)\) and \(A{k}(z)\) are numerator and denominator of the transfer function of the k-th second order section.

**Parameters**

- `sos` : array_like
  Array of second-order filter coefficients, must have shape (n_sections, 6). Each row corresponds to a second-order section, with the first three columns providing the numerator coefficients and the last three providing the denominator coefficients.

- `worN` : {None, int, array_like}, optional
  If None (default), then compute at 512 frequencies equally spaced around the unit circle. If a single integer, then compute at that many frequencies. Using a number that is fast for FFT computations can result in faster computations (see Notes of `freqz`). If an array_like, compute the response at the frequencies given (in radians/sample; must be 1D).

- `whole` : bool, optional

5.20. Signal processing (scipy.signal) 1129
Normally, frequencies are computed from 0 to the Nyquist frequency, \( \pi \) radians/sample (upper-half of unit-circle). If \textit{whole} is True, compute frequencies from 0 to \( 2\pi \) radians/sample.

**Returns**

- \textit{w} : ndarray
  The normalized frequencies at which \( h \) was computed, in radians/sample.

- \textit{h} : ndarray
  The frequency response, as complex numbers.

**See also:**

- \textit{freqz}
- \textit{sosfilt}

**Notes**

New in version 0.19.0.

**Examples**

Design a 15th-order bandpass filter in SOS format.

```python
>>> from scipy import signal
>>> sos = signal.ellip(15, 0.5, 60, (0.2, 0.4), btype='bandpass',
... output='sos')
```

Compute the frequency response at 1500 points from DC to Nyquist.

```python
>>> w, h = signal.sosfreqz(sos, worN=1500)
```

Plot the response.

```python
>>> import matplotlib.pyplot as plt
>>> plt.subplot(2, 1, 1)
>>> db = 20*np.log10(np.abs(h))
>>> plt.plot(w/np.pi, db)
>>> plt.ylim(-75, 5)
>>> plt.grid(True)
>>> plt.yticks([-np.pi, -0.5*np.pi, 0, 0.5*np.pi, np.pi],
... [r'$-\pi$', r'$-\pi/2$', '0', r'$\pi/2$', r'$\pi$'])
>>> plt.ylabel('Gain [dB]')
>>> plt.title('Frequency Response')
>>> plt.subplot(2, 1, 2)
>>> plt.plot(w/np.pi, np.angle(h))
>>> plt.grid(True)
>>> plt.yticks([-np.pi, -0.5*np.pi, 0, 0.5*np.pi, np.pi],
... [r'$-\pi$', r'$-\pi/2$', '0', r'$\pi/2$', r'$\pi$'])
>>> plt.ylabel('Phase [rad]')
>>> plt.xlabel('Normalized frequency (1.0 = Nyquist)')
>>> plt.show()
```
If the same filter is implemented as a single transfer function, numerical error corrupts the frequency response:

```python
>>> b, a = signal.ellip(15, 0.5, 60, (0.2, 0.4), btype='bandpass',
                      output='ba')
>>> w, h = signal.freqz(b, a, worN=1500)
>>> db = 20*np.log10(np.abs(h))
>>> plt.plot(w/np.pi, db)
>>> plt.subplot(2, 1, 2)
>>> plt.plot(w/np.pi, np.angle(h))
>>> plt.show()
```

scipy.signal.group_delay(system, w=None, whole=False)

Compute the group delay of a digital filter.

The group delay measures by how many samples amplitude envelopes of various spectral components of a signal are delayed by a filter. It is formally defined as the derivative of continuous (unwrapped) phase:
$$D(w) = \frac{d}{dw} \arg H(e)$$

Parameters

*system*: tuple of array_like (b, a)

Numerator and denominator coefficients of a filter transfer function.

*w*: {None, int, array-like}, optional

If None (default), then compute at 512 frequencies equally spaced around
the unit circle. If a single integer, then compute at that many frequencies. If
array, compute the delay at the frequencies given (in radians/sample).

*whole*: bool, optional

Normally, frequencies are computed from 0 to the Nyquist frequency, \(\pi\) radians/sample (upper-half of unit-circle). If *whole* is True, compute fre-
quencies from 0 to \(2\pi\) radians/sample.

Returns

*w*: ndarray

The normalized frequencies at which the group delay was computed, in
radians/sample.

*gd*: ndarray

The group delay.

See also:

freqz

Frequency response of a digital filter

Notes

The similar function in MATLAB is called *grpdelay*.

If the transfer function \(H(z)\) has zeros or poles on the unit circle, the group delay at corresponding frequencies
is undefined. When such a case arises the warning is raised and the group delay is set to 0 at those frequencies.

For the details of numerical computation of the group delay refer to [R258].

References

[R258]

Examples

```python
>>> from scipy import signal
>>> b, a = signal.iirdesign(0.1, 0.3, 5, 50, ftype='cheby1')
>>> w, gd = signal.group_delay((b, a))

>>> import matplotlib.pyplot as plt
>>> plt.title('Digital filter group delay')
>>> plt.plot(w, gd)
>>> plt.ylabel('Group delay [samples]')
>>> plt.xlabel('Frequency [rad/sample]')
>>> plt.show()
```
scipy.signal.iirdesign(wp, ws, gpass, gstop, analog=False, ftype='ellip', output='ba')

Digital filter group delay

Complete IIR digital and analog filter design.

Given passband and stopband frequencies and gains, construct an analog or digital IIR filter of minimum order for a given basic type. Return the output in numerator, denominator (‘ba’), pole-zero (‘zpk’) or second order sections (‘sos’) form.

**Parameters**

- **wp, ws**: float
  Passband and stopband edge frequencies. For digital filters, these are normalized from 0 to 1, where 1 is the Nyquist frequency, pi radians/sample. (wp and ws are thus in half-cycles/sample.) For example:
  - **Lowpass**: \( wp = 0.2, ws = 0.3 \)
  - **Highpass**: \( wp = 0.7, ws = 0.2 \)
  - **Bandpass**: \( wp = [0.2, 0.5], ws = [0.1, 0.6] \)
  - **Bandstop**: \( wp = [0.1, 0.6], ws = [0.2, 0.5] \)

  For analog filters, \( wp \) and \( ws \) are angular frequencies (e.g. rad/s).

- **gpass**: float
  The maximum loss in the passband (dB).

- **gstop**: float
  The minimum attenuation in the stopband (dB).

- **analog**: bool, optional
  When True, return an analog filter, otherwise a digital filter is returned.

- **ftype**: str, optional
  The type of IIR filter to design:
  - **Butterworth**: ‘butter’
  - **Chebyshev I**: ‘cheby1’
  - **Chebyshev II**: ‘cheby2’
  - **Cauer/Elliptic**: ‘ellip’
  - **Bessel/Thomson**: ‘bessel’

- **output**: {‘ba’, ‘zpk’, ‘sos’}, optional
  Type of output: numerator/denominator (‘ba’), pole-zero (‘zpk’), or second-order sections (‘sos’). Default is ‘ba’.

**Returns**

- **b, a**: ndarray, ndarray
  Numerator (\( b \)) and denominator (\( a \)) polynomials of the IIR filter. Only returned if \( output='ba' \).

- **z, p, k**: ndarray, ndarray, float
  Zeros, poles, and system gain of the IIR filter transfer function. Only returned if \( output='zpk' \).

- **sos**: ndarray

5.20. Signal processing (scipy.signal)
Second-order sections representation of the IIR filter. Only returned if output=='sos'.

See also:

- **butter**: Filter design using order and critical points
- **cheby1, cheby2, ellip, bessel**
- **buttord**: Find order and critical points from passband and stopband spec
- **cheb1ord, cheb2ord, ellipord**
- **iirfilter**: General filter design using order and critical frequencies

Notes

The 'sos' output parameter was added in 0.16.0.

```python
scipy.signal.iirfilter(N, Wn, rp=None, rs=None, btype='band', analog=False, ftype='butter', output='ba')
```

IIR digital and analog filter design given order and critical points.

Design an Nth-order digital or analog filter and return the filter coefficients.

**Parameters**

- **N**: int
  - The order of the filter.
- **Wn**: array_like
  - A scalar or length-2 sequence giving the critical frequencies. For digital filters, Wn is normalized from 0 to 1, where 1 is the Nyquist frequency, pi radians/sample. (Wn is thus in half-cycles / sample.) For analog filters, Wn is an angular frequency (e.g. rad/s).
- **rp**: float, optional
  - For Chebyshev and elliptic filters, provides the maximum ripple in the passband. (dB)
- **rs**: float, optional
  - For Chebyshev and elliptic filters, provides the minimum attenuation in the stop band. (dB)
- **btype**: {'bandpass', 'lowpass', 'highpass', 'bandstop'}, optional
  - The type of filter. Default is 'bandpass'.
- **analog**: bool, optional
  - When True, return an analog filter, otherwise a digital filter is returned.
- **ftype**: str, optional
  - The type of IIR filter to design:
    - Butterworth: 'butter'
    - Chebyshev I: 'cheby1'
    - Chebyshev II: 'cheby2'
    - Cauer/elliptic: 'ellip'
    - Bessel/Thomson: 'bessel'
- **output**: {'ba', 'zpk', 'sos'}, optional
  - Type of output: numerator/denominator ('ba'), pole-zero ('zpk'), or second-order sections ('sos'). Default is 'ba'.

**Returns**

- **b, a**: ndarray, ndarray
  - Numerator (b) and denominator (a) polynomials of the IIR filter. Only returned if output='ba'.
- **z, p, k**: ndarray, ndarray, float
  - Zeros, poles, and system gain of the IIR filter transfer function. Only returned if output='zpk'.
- **sos**: ndarray
  - Second-order sections representation of the IIR filter. Only returned if output=='sos'.

**Examples**

Generate a 17th-order Chebyshev II bandpass filter and plot the frequency response:

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> b, a = signal.iirfilter(17, [50, 200], rs=60, btype='band',
...                        analog=True, ftype='cheby2')
>>> w, h = signal.freqs(b, a, 1000)
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.semilogx(w, 20 * np.log10(abs(h)))
>>> ax.set_title('Chebyshev Type II bandpass frequency response')
>>> ax.set_xlabel('Frequency [radians / second]')
>>> ax.set_ylabel('Amplitude [dB]')
>>> ax.axis((10, 1000, -100, 10))
>>> ax.grid(which='both', axis='both')
>>> plt.show()

scipy.signal.kaiser_atten(numtaps, width)

Compute the attenuation of a Kaiser FIR filter.

Given the number of taps $N$ and the transition width $width$, compute the attenuation $a$ in dB, given by Kaiser's formula:

$$ a = 2.285 \times (N - 1) \times \pi \times width + 7.95 $$
**SciPy Reference Guide, Release 1.0.0**

**Parameters**

- `numtaps` : int
  The number of taps in the FIR filter.

- `width` : float
  The desired width of the transition region between passband and stopband (or, in general, at any discontinuity) for the filter, expressed as a fraction of the Nyquist frequency.

**Returns**

- `a` : float
  The attenuation of the ripple, in dB.

**See also:**

- `kaiserord`, `kaiser_beta`

**Examples**

Suppose we want to design a FIR filter using the Kaiser window method that will have 211 taps and a transition width of 9 Hz for a signal that is sampled at 480 Hz. Expressed as a fraction of the Nyquist frequency, the width is \(9/(0.5*480) = 0.0375\). The approximate attenuation (in dB) is computed as follows:

```python
>>> from scipy.signal import kaiser_atten
>>> kaiser_atten(211, 0.0375)
64.48099630593983
```

scipy.signal.kaiser_beta(a)

Compute the Kaiser parameter \(\beta\), given the attenuation \(a\).

**Parameters**

- `a` : float
  The desired attenuation in the stopband and maximum ripple in the passband, in dB. This should be a positive number.

**Returns**

- `beta` : float
  The \(\beta\) parameter to be used in the formula for a Kaiser window.

**References**

**Examples**

Suppose we want to design a lowpass filter, with 65 dB attenuation in the stop band. The Kaiser window parameter to be used in the window method is computed by `kaiser_beta(65)`:.

```python
>>> from scipy.signal import kaiser_beta
>>> kaiser_beta(65)
6.20426
```

scipy.signal.kaiserord(ripple, width)

Determine the filter window parameters for the Kaiser window method.

The parameters returned by this function are generally used to create a finite impulse response filter using the window method, with either `firwin` or `firwin2`.

**Parameters**

- `ripple` : float
  Upper bound for the deviation (in dB) of the magnitude of the filter’s frequency response from that of the desired filter (not including frequencies in any transition intervals). That is, if \(w\) is the frequency expressed as a fraction of the Nyquist frequency, \(A(w)\) is the actual frequency response of the filter and \(D(w)\) is the desired frequency response, the design requirement is that:

```
abs(A(w) - D(w))) < 10**(ripple/20)

for 0 <= w <= 1 and w not in a transition interval.

width : float
    Width of transition region, normalized so that 1 corresponds to pi radians / sample. That is, the frequency is expressed as a fraction of the Nyquist frequency.

Returns

numtaps : int
    The length of the Kaiser window.

beta : float
    The beta parameter for the Kaiser window.

See also:

kaiser_beta, kaiser_atten

Notes

There are several ways to obtain the Kaiser window:

* signal.kaiser(numtaps, beta, sym=True)
* signal.get_window(beta, numtaps)
* signal.get_window(('kaiser', beta), numtaps)

The empirical equations discovered by Kaiser are used.

References

Examples

We will use the Kaiser window method to design a lowpass FIR filter for a signal that is sampled at 1000 Hz.

We want at least 65 dB rejection in the stop band, and in the pass band the gain should vary no more than 0.5%.

We want a cutoff frequency of 175 Hz, with a transition between the pass band and the stop band of 24 Hz. That is, in the band [0, 163], the gain varies no more than 0.5%, and in the band [187, 500], the signal is attenuated by at least 65 dB.

```python
>>> from scipy.signal import kaiserord, firwin, freqz
>>> import matplotlib.pyplot as plt
```

```python
>>> fs = 1000.0
>>> cutoff = 175
>>> width = 24
```

The Kaiser method accepts just a single parameter to control the pass band ripple and the stop band rejection, so we use the more restrictive of the two. In this case, the pass band ripple is 0.005, or 46.02 dB, so we will use 65 dB as the design parameter.

Use kaiserord to determine the length of the filter and the parameter for the Kaiser window.

```python
>>> numtaps, beta = kaiserord(65, width/(0.5*fs))
>>> numtaps
167
>>> beta
6.20426
```

Use firwin to create the FIR filter.

```python
>>> taps = firwin(numtaps, cutoff, window=('kaiser', beta),
                 ... scale=False, nyq=0.5*fs)
```
Compute the frequency response of the filter. \( w \) is the array of frequencies, and \( h \) is the corresponding complex array of frequency responses.

```
>>> w, h = freqz(taps, worN=8000)
>>> w *= 0.5*fs/np.pi  # Convert w to Hz.
```

Compute the deviation of the magnitude of the filter’s response from that of the ideal lowpass filter. Values in the transition region are set to \( \text{nan} \), so they won’t appear in the plot.

```
>>> ideal = w < cutoff  # The "ideal" frequency response.
>>> deviation = np.abs(np.abs(h) - ideal)
>>> deviation[(w > cutoff - 0.5*width) & (w < cutoff + 0.5*width)] = np.nan
```

Plot the deviation. A close look at the left end of the stop band shows that the requirement for 65 dB attenuation is violated in the first lobe by about 0.125 dB. This is not unusual for the Kaiser window method.

```
>>> plt.plot(w, 20*np.log10(np.abs(deviation)))
>>> plt.xlim(0, 0.5*fs)
>>> plt.ylim(-90, -60)
>>> plt.grid(alpha=0.25)
>>> plt.axhline(-65, color='r', ls='--', alpha=0.3)
>>> plt.xlabel('Frequency (Hz)')
>>> plt.ylabel('Deviation from ideal (dB)')
>>> plt.title('Lowpass Filter Frequency Response')
>>> plt.show()
```

```
>>> scipy.signal.minimum_phase(h, method='homomorphic', n_fft=None)
```

Convert a linear-phase FIR filter to minimum phase

**Parameters**

- **h**: array
  Linear-phase FIR filter coefficients.
- **method**: ['hilbert', 'homomorphic']
  The method to use:
  - `'homomorphic'` (default)
    This method [R289] [R290] works best with filters with an odd number of taps, and the resulting minimum phase filter will have a magnitude response that approximates the
square root of the original filter’s magnitude response.

`hilbert`  This method [R286] is designed to be used with equiripple filters (e.g., from `remez`) with unity or zero gain regions.

```
n_fft : int
    The number of points to use for the FFT. Should be at least a few times larger than the signal length (see Notes).

Returns
```
```
h_minimum : array
    The minimum-phase version of the filter, with length \((\text{length}(h) + 1) / 2\).```

See also:
```
`firwin`, `firwin2`, `remez`
```

Notes
Both the Hilbert [R286] or homomorphic [R289] [R290] methods require selection of an FFT length to estimate the complex cepstrum of the filter.

In the case of the Hilbert method, the deviation from the ideal spectrum \(\epsilon\) is related to the number of stopband zeros \(n_{\text{stop}}\) and FFT length \(n_{\text{fft}}\) as:

\[
\epsilon = 2 \times n_{\text{stop}} / n_{\text{fft}}
\]

For example, with 100 stopband zeros and a FFT length of 2048, \(\epsilon = 0.0976\). If we conservatively assume that the number of stopband zeros is one less than the filter length, we can take the FFT length to be the next power of 2 that satisfies \(\epsilon=0.01\) as:

```
n_fft = 2 ** int(np.ceil(np.log2(2 * (len(h) - 1) / 0.01)))
```

This gives reasonable results for both the Hilbert and homomorphic methods, and gives the value used when \(n_{\text{fft}}=\text{None}\).

Alternative implementations exist for creating minimum-phase filters, including zero inversion [R287] and spectral factorization [R288] [R289]. For more information, see:

```
http://dspguru.com/dsp/howtos/how-to-design-minimum-phase-fir-filters
```

References
[R286], [R287], [R288], [R289], [R290]

Examples
Create an optimal linear-phase filter, then convert it to minimum phase:

```
>>> from scipy.signal import remez, minimum_phase, freqz, group_delay
>>> import matplotlib.pyplot as plt
>>> freq = [0, 0.2, 0.3, 1.0]
>>> desired = [1, 0]
>>> h_linear = remez(151, freq, desired, Hz=2.)
```

Convert it to minimum phase:

```
>>> h_min_hom = minimum_phase(h_linear, method='homomorphic')
>>> h_min_hil = minimum_phase(h_linear, method='hilbert')
```

Compare the three filters:
```python
>>> fig, axs = plt.subplots(4, figsize=(4, 8))
>>> for h, style, color in zip((h_linear, h_min_hom, h_min_hil), ('-', '-', '-'), ('k', 'r', 'c')):
...     w, H = freqz(h)
...     w, gd = group_delay((h, 1))
...     w /= np.pi
...     axs[0].plot(h, color=color, linestyle=style)
...     axs[1].plot(w, np.abs(H), color=color, linestyle=style)
...     axs[2].plot(w, 20 * np.log10(np.abs(H)), color=color, linestyle=style)
...     axs[3].plot(w, gd, color=color, linestyle=style)
>>> for ax in axs:
...     ax.grid(True, color='0.5')
...     ax.fill_between(freq[1:3], *ax.get_ylim(), color='#ffeeaa', zorder=1)
>>> axs[0].set(xlim=[0, len(h_linear) - 1], ylabel='Amplitude', xlabel='Samples')
>>> axs[1].legend(['Linear', 'Min-Hom', 'Min-Hil'], title='Phase')
>>> for ax, ylim in zip(axs[1:], ([0, 1.1], [-150, 10], [-60, 60])):
...     ax.set(xlim=[0, 1], ylim=ylim, xlabel='Frequency')
>>> axs[1].set(ylim='Magnitude')
>>> axs[2].set(ylim='Magnitude (dB)')
>>> axs[3].set(ylim='Group delay')
>>> plt.tight_layout()
```
scipy.signal.savgol_coeffs(window_length, polyorder, deriv=0, delta=1.0, pos=None, use='conv')

Compute the coefficients for a 1-d Savitzky-Golay FIR filter.

Parameters:
- window_length : int
  The length of the filter window (i.e. the number of coefficients).
The order of the polynomial used to fit the samples. `polyorder` must be less than `window_length`.

- **deriv**: int, optional
  The order of the derivative to compute. This must be a nonnegative integer. The default is 0, which means to filter the data without differentiating.

- **delta**: float, optional
  The spacing of the samples to which the filter will be applied. This is only used if `deriv > 0`.

- **pos**: int or None, optional
  If `pos` is not None, it specifies evaluation position within the window. The default is the middle of the window.

- **use**: str, optional
  Either ‘conv’ or ‘dot’. This argument chooses the order of the coefficients. The default is ‘conv’, which means that the coefficients are ordered to be used in a convolution. With use='dot', the order is reversed, so the filter is applied by dotting the coefficients with the data set.

**Returns**

- **coeffs**: 1-d ndarray
  The filter coefficients.

**See also:**

- `savgol_filter`

**Notes**

New in version 0.14.0.

**References**

**Examples**

```python
>>> from scipy.signal import savgol_coeffs
>>> savgol_coeffs(5, 2)
array([-0.08571429, 0.34285714, 0.48571429, 0.34285714, -0.08571429])
>>> savgol_coeffs(5, 2, deriv=1)
array([ 2.00000000e-01, 1.00000000e-01, 2.00607895e-16, -1.00000000e-01, -2.00000000e-01])
```

Note that use='dot' simply reverses the coefficients.

```python
>>> savgol_coeffs(5, 2, pos=3)
array([ 0.25714286, 0.37142857, 0.34285714, 0.17142857, -0.14285714])
>>> savgol_coeffs(5, 2, pos=3, use='dot')
array([-0.14285714, 0.17142857, 0.34285714, 0.37142857, 0.25714286])
```

`x` contains data from the parabola `x = t**2`, sampled at `t = -1, 0, 1, 2, 3`. `c` holds the coefficients that will compute the derivative at the last position. When dotted with `x` the result should be 6.

```python
>>> x = np.array([1, 0, 1, 4, 9])
>>> c = savgol_coeffs(5, 2, pos=4, deriv=1, use='dot')
>>> c.dot(x)
6.0000000000000018
```
Calculate the minimax optimal filter using the Remez exchange algorithm.

Calculate the filter-coefficients for the finite impulse response (FIR) filter whose transfer function minimizes the maximum error between the desired gain and the realized gain in the specified frequency bands using the Remez exchange algorithm.

Parameters

- `numtaps`: int
  The desired number of taps in the filter. The number of taps is the number of terms in the filter, or the filter order plus one.

- `bands`: array_like
  A monotonic sequence containing the band edges. All elements must be non-negative and less than half the sampling frequency as given by `fs`.

- `desired`: array_like
  A sequence half the size of bands containing the desired gain in each of the specified bands.

- `weight`: array_like, optional
  A relative weighting to give to each band region. The length of `weight` has to be half the length of `bands`.

- `Hz`: scalar, optional
  Deprecated. Use ‘fs’ instead. The sampling frequency in Hz. Default is 1.

- `type`: {'bandpass', 'differentiator', 'hilbert'}, optional
  The type of filter:
  - 'bandpass': flat response in bands. This is the default.
  - 'differentiator': frequency proportional response in bands.
  - 'hilbert' [filter with odd symmetry, that is, type III] (for even order) or type IV (for odd order) linear phase filters.

- `maxiter`: int, optional
  Maximum number of iterations of the algorithm. Default is 25.

- `grid_density`: int, optional
  Grid density. The dense grid used in `remez` is of size `(numtaps + 1) * grid_density`. Default is 16.

- `fs`: float, optional
  The sampling frequency of the signal. Default is 1.

Returns

- `out`: ndarray
  A rank-1 array containing the coefficients of the optimal (in a minimax sense) filter.

See also:

- `firls`, `firwin`, `firwin2`, `minimum_phase`

References

[R296], [R297]

Examples

For a signal sampled at 100 Hz, we want to construct a filter with a passband at 20-40 Hz, and stop bands at 0-10 Hz and 45-50 Hz. Note that this means that the behavior in the frequency ranges between those bands is unspecified and may overshoot.

```python
>>> from scipy import signal
>>> fs = 100
>>> bpass = signal.remez(72, [0, 10, 20, 40, 45, 50], [0, 1, 0], fs=fs)
>>> freq, response = signal.freqz(bpass)
```
```python
>>> import matplotlib.pyplot as plt
>>> plt.semilogy(0.5*fs*freq/np.pi, np.abs(response), 'b-')
>>> plt.grid(alpha=0.25)
>>> plt.xlabel('Frequency (Hz)')
>>> plt.ylabel('Gain')
>>> plt.show()
```

```python
scipy.signal.unique_roots(p, tol=0.001, rtype='min')
```

Determine unique roots and their multiplicities from a list of roots.

**Parameters**

- `p`: array_like
  The list of roots.
- `tol`: float, optional
  The tolerance for two roots to be considered equal. Default is 1e-3.
- `rtype`: {'max', 'min', 'avg'}, optional
  How to determine the returned root if multiple roots are within `tol` of each other.
  - `max`: pick the maximum of those roots.
  - `min`: pick the minimum of those roots.
  - `avg`: take the average of those roots.

**Returns**

- `pout`: ndarray
  The list of unique roots, sorted from low to high.
- `mult`: ndarray
  The multiplicity of each root.

**Notes**

This utility function is not specific to roots but can be used for any sequence of values for which uniqueness and multiplicity has to be determined. For a more general routine, see `numpy.unique`.

**Examples**

```python
>>> from scipy import signal
>>> vals = [0, 1.3, 1.31, 2.8, 1.25, 2.2, 10.3]
>>> uniq, mult = signal.unique_roots(vals, tol=2e-2, rtype='avg')
```

Check which roots have multiplicity larger than 1:
Compute partial-fraction expansion of \( b(s) / a(s) \).

If \( M \) is the degree of numerator \( b \) and \( N \) the degree of denominator \( a \):

\[
H(s) = \frac{b(s)}{a(s)} = \frac{b[0] s^M + b[1] s^{M-1} + \ldots + b[M]}{a[0] s^N + a[1] s^{N-1} + \ldots + a[N]}
\]

then the partial-fraction expansion \( H(s) \) is defined as:

\[
\frac{r[0]}{(s-p[0])} + \frac{r[1]}{(s-p[1])} + \ldots + \frac{r[-1]}{(s-p[-1])}
\]

If there are any repeated roots (closer together than \( tol \)), then \( H(s) \) has terms like:

\[
\frac{r[i]}{(s-p[i])} + \frac{r[i+1]}{(s-p[i])^2} + \ldots + \frac{r[i+n-1]}{(s-p[i])^n}
\]

This function is used for polynomials in positive powers of \( s \) or \( z \), such as analog filters or digital filters in controls engineering. For negative powers of \( z \) (typical for digital filters in DSP), use \( \text{residuez} \).

**Parameters**

- \( b \) : array_like
  Numerator polynomial coefficients.
- \( a \) : array_like
  Denominator polynomial coefficients.

**Returns**

- \( r \) : ndarray
  Residues.
- \( p \) : ndarray
  Poles.
- \( k \) : ndarray
  Coefficients of the direct polynomial term.

**See also:**

- \( \text{invres} \), \( \text{residuez} \), \( \text{numpy.poly} \), \( \text{unique_roots} \)

***SciPy Reference Guide, Release 1.0.0***

5.20. Signal processing (scipy.signal) 1145
This function is used for polynomials in negative powers of \( z \), such as digital filters in DSP. For positive powers, use `residue`.

\[
\begin{align*}
    r[i] & \quad r[i+1] & \quad r[i+n-1] \\
    \frac{1}{1-p[i]z^{-1}} & + \frac{1}{(1-p[i]z^{-1})^2} & + \cdots & + \frac{1}{(1-p[i]z^{-1})^n}
\end{align*}
\]

**Parameters**  
- \( b \) : array_like  
  Numerator polynomial coefficients.
- \( a \) : array_like  
  Denominator polynomial coefficients.

**Returns**  
- \( r \) : ndarray  
  Residues.
- \( p \) : ndarray  
  Poles.
- \( k \) : ndarray  
  Coefficients of the direct polynomial term.

**See also:**  
`invresz`, `residue`, `unique_roots`

SCIPY*SIGNAL.

## invres(r, p, k, tol=0.001, rtype='avg')

Compute \( b(s) \) and \( a(s) \) from partial fraction expansion. If \( M \) is the degree of numerator \( b \) and \( N \) the degree of denominator \( a \):

\[
H(s) = \frac{b(s)}{a(s)} = \frac{b[0]}{a[0]} s^{(M)} + \frac{b[1]}{a[1]} s^{(M-1)} + \ldots + \frac{b[M]}{a[N]} s^{(N-1)} + \ldots + \frac{b[N]}{a[N]}
\]

then the partial-fraction expansion \( H(s) \) is defined as:

\[
\begin{align*}
    r[0] & \quad r[1] & \quad r[-1] \\
    \frac{1}{(s-p[0])} & + \frac{1}{(s-p[1])} & + \frac{1}{(s-p[-1])} + k(s)
\end{align*}
\]

If there are any repeated roots (closer together than \( tol \)), then \( H(s) \) has terms like:

\[
\begin{align*}
    r[i] & \quad r[i+1] & \quad r[i+n-1] \\
    \frac{1}{(s-p[i])} & + \frac{1}{(s-p[i])^2} & + \cdots & + \frac{1}{(s-p[i])^n}
\end{align*}
\]

This function is used for polynomials in positive powers of \( s \) or \( z \), such as analog filters or digital filters in controls engineering. For negative powers of \( z \) (typical for digital filters in DSP), use `invresz`.

**Parameters**  
- \( r \) : array_like  
  Residues.
- \( p \) : array_like  
  Poles.
- \( k \) : array_like  
  Coefficients of the direct polynomial term.
- \( tol \) : float, optional  
  The tolerance for two roots to be considered equal. Default is 1e-3.
- \( rtype \) : ['max', 'min', 'avg'], optional  
  How to determine the returned root if multiple roots are within \( tol \) of each other.
  - 'max': pick the maximum of those roots.
  - 'min': pick the minimum of those roots.
Returns

- **b**: ndarray
  Numerator polynomial coefficients.
- **a**: ndarray
  Denominator polynomial coefficients.

See also:

- `residue`, `invresz`, `unique_roots`

**scipy.signal.invresz(r, p, k, tol=0.001, rtype='avg')**

Compute b(z) and a(z) from partial fraction expansion.

If $M$ is the degree of numerator $b$ and $N$ the degree of denominator $a$:

\[
\frac{b(z)}{a(z)} = \frac{b[0] + b[1] z**(-1) + \cdots + b[M] z**(-M)}{a[0] + a[1] z**(-1) + \cdots + a[N] z**(-N)}
\]

then the partial-fraction expansion $H(z)$ is defined as:

\[
\begin{align*}
    r[0] & \quad r[-1] \\
    \frac{r[0]}{(1-p[0]z**(-1))} + \frac{\cdots + \frac{\cdots + k[0] + k[1]z**(-1) \ldots \frac{r[-1]}{(1-p[-1]z**(-1))}}{(1-p[-1]z**(-1))}}{(1-p[-1]z**(-1))}
\end{align*}
\]

If there are any repeated roots (closer than `tol`), then the partial fraction expansion has terms like:

\[
\begin{align*}
    r[i] & \quad r[i+1] & \quad r[i+n-1] \\
    \frac{r[i]}{(1-p[i]z**(-1))} + \frac{\cdots + \frac{\cdots + r[i+n-1]}{(1-p[i]z**(-1))**2} + \cdots (1-p[i]z**(-1))**n}}{(1-p[i]z**(-1))**n}
\end{align*}
\]

This function is used for polynomials in negative powers of $z$, such as digital filters in DSP. For positive powers, use `invres`.

**Parameters**

- **r**: array_like
  Residues.
- **p**: array_like
  Poles.
- **k**: array_like
  Coefficients of the direct polynomial term.
- **tol**: float, optional
  The tolerance for two roots to be considered equal. Default is 1e-3.
- **rtype**: {'max', 'min', 'avg'}, optional
  How to determine the returned root if multiple roots are within `tol` of each other.
  - 'max': pick the maximum of those roots.
  - 'min': pick the minimum of those roots.
  - 'avg': take the average of those roots.

**Returns**

- **b**: ndarray
  Numerator polynomial coefficients.
- **a**: ndarray
  Denominator polynomial coefficients.

**Exception** `scipy.signal.BadCoefficients`

Warning about badly conditioned filter coefficients

Lower-level filter design functions:
### scipy.signal.abcd_normalize

**Check state-space matrices and ensure they are two-dimensional.**

**Parameters**

- `A`, `B`, `C`, `D`: array_like, optional
  - State-space matrices. All of them are None (missing) by default. See `ss2tf` for format.

**Returns**

- `A`, `B`, `C`, `D`: array
  - Properly shaped state-space matrices.

**Raises**

- `ValueError`
  - If not enough information on the system was provided.

### scipy.signal.band_stop_obj

**Band Stop Objective Function for order minimization.**

**Parameters**

- `wp`, `ind`, `passb`, `stopb`, `gpass`, ...
  - Edge of passband `passb`.

- `ind`: int, `{0, 1}`
  - Index specifying which `passb` edge to vary (0 or 1).

- `passb`: ndarray
  - Two element sequence of fixed passband edges.

- `stopb`: ndarray
  - Two element sequence of fixed stopband edges.

- `gstop`: float
  - Amount of attenuation in stopband in dB.

- `gpass`: float
  - Amount of ripple in the passband in dB.

- `type`: {'butter', 'cheby', 'ellip'}
  - Type of filter.

**Returns**

- `n`: scalar
  - Non-integer order for an analog band stop filter.
Filter order (possibly non-integer).

```python
scipy.signal.besselap(N, norm='phase')
```
Return (z,p,k) for analog prototype of an Nth-order Bessel filter.

**Parameters**

- `N : int`
The order of the filter.
- `norm : {'phase', 'delay', 'mag'}, optional`
  Frequency normalization:
  - `phase`: The filter is normalized such that the phase response reaches its midpoint at an angular (e.g. rad/s) cutoff frequency of 1. This happens for both low-pass and high-pass filters, so this is the “phase-matched” case. [R235]
  The magnitude response asymptotes are the same as a Butterworth filter of the same order with a cutoff of \( W_n \).
  This is the default, and matches MATLAB’s implementation.
  - `delay`: The filter is normalized such that the group delay in the passband is 1 (e.g. 1 second). This is the “natural” type obtained by solving Bessel polynomials.
  - `mag`: The filter is normalized such that the gain magnitude is -3 dB at angular frequency 1. This is called “frequency normalization” by Bond. [R230]

**Returns**

- `z : ndarray`
  Zeros of the transfer function. Is always an empty array.
- `p : ndarray`
  Poles of the transfer function.
- `k : scalar`
  Gain of the transfer function. For phase-normalized, this is always 1.

See also:

- `bessel` Filter design function using this prototype

Notes

To find the pole locations, approximate starting points are generated [R231] for the zeros of the ordinary Bessel polynomial [R232], then the Aberth-Ehrlich method [R233] [R234] is used on the \( K_v(x) \) Bessel function to calculate more accurate zeros, and these locations are then inverted about the unit circle.

References

[R230], [R231], [R232], [R233], [R234], [R235]

```python
scipy.signal.buttap(N)
```
Return (z,p,k) for analog prototype of Nth-order Butterworth filter.

The filter will have an angular (e.g. rad/s) cutoff frequency of 1.

See also:

- `butter` Filter design function using this prototype

```python
scipy.signal.cheb1ap(N, rp)
```
Return (z,p,k) for Nth-order Chebyshev type I analog lowpass filter.

The returned filter prototype has \( rp \) decibels of ripple in the passband.

The filter's angular (e.g. rad/s) cutoff frequency is normalized to 1, defined as the point at which the gain first drops below \(-rp\).

See also:
cheby1  Filter design function using this prototype

scipy.signal.cheb2ap(N, rs)

Return (z,p,k) for Nth-order Chebyshev type I analog lowpass filter.

The returned filter prototype has rs decibels of ripple in the stopband.

The filter’s angular (e.g. rad/s) cutoff frequency is normalized to 1, defined as the point at which the gain first reaches -rs.

See also:

cheby2  Filter design function using this prototype

scipy.signal.cmplx_sort(p)

Sort roots based on magnitude.

Parameters  p : array_like

Returns  p_sorted : ndarray

Sorted roots.

indx : ndarray

Array of indices needed to sort the input p.

scipy.signal.ellipap(N, rp, rs)

Return (z,p,k) of Nth-order elliptic analog lowpass filter.

The filter is a normalized prototype that has rp decibels of ripple in the passband and a stopband rs decibels down.

The filter’s angular (e.g. rad/s) cutoff frequency is normalized to 1, defined as the point at which the gain first drops below -rp.

See also:

ellip  Filter design function using this prototype

References

[R251]

scipy.signal.lp2bp(b, a, wo=1.0, bw=1.0)

Transform a lowpass filter prototype to a bandpass filter.

Return an analog band-pass filter with center frequency wo and bandwidth bw from an analog low-pass filter prototype with unity cutoff frequency, in transfer function (‘ba’) representation.

scipy.signal.lp2bs(b, a, wo=1.0, bw=1.0)

Transform a lowpass filter prototype to a bandstop filter.

Return an analog band-stop filter with center frequency wo and bandwidth bw from an analog low-pass filter prototype with unity cutoff frequency, in transfer function (‘ba’) representation.

scipy.signal.lp2hp(b, a, wo=1.0)

Transform a lowpass filter prototype to a highpass filter.

Return an analog high-pass filter with cutoff frequency wo from an analog low-pass filter prototype with unity cutoff frequency, in transfer function (‘ba’) representation.

scipy.signal.lp2lp(b, a, wo=1.0)

Transform a lowpass filter prototype to a different frequency.

Return an analog low-pass filter with cutoff frequency wo from an analog low-pass filter prototype with unity cutoff frequency, in transfer function (‘ba’) representation.
scipy.signal.normalize \((b, a)\)

Normalize numerator/denominator of a continuous-time transfer function.

If values of \(b\) are too close to 0, they are removed. In that case, a BadCoefficients warning is emitted.

**Parameters**

\(b\): array_like

Numerator of the transfer function. Can be a 2d array to normalize multiple transfer functions.

\(a\): array_like

Denominator of the transfer function. At most 1d.

**Returns**

num: array

The numerator of the normalized transfer function. At least a 1d array. A 2d-array if the input \(num\) is a 2d array.

den: 1d-array

The denominator of the normalized transfer function.

**Notes**

Coefficients for both the numerator and denominator should be specified in descending exponent order (e.g., \(s^2 + 3s + 5\) would be represented as \([1, 3, 5]\)).

### 5.20.5 Matlab-style IIR filter design

**butter**\((N, Wn[, btype, analog, output])\)

Butterworth digital and analog filter design.

Design an Nth-order digital or analog Butterworth filter and return the filter coefficients.

**Parameters**

\(N\): int

The order of the filter.

\(Wn\): array_like

A scalar or length-2 sequence giving the critical frequencies. For a Butterworth filter, this is the point at which the gain drops to 1/sqrt(2) that of the passband (the “-3 dB point”). For digital filters, \(Wn\) is normalized from 0 to 1, where 1 is the Nyquist frequency, pi radians/sample. (\(Wn\) is thus in half-cycles / sample.) For analog filters, \(Wn\) is an angular frequency (e.g. rad/s).

\(btype\): {'lowpass', 'highpass', 'bandpass', 'bandstop'}, optional

The type of filter. Default is ‘lowpass’.

\(analog\): bool, optional

When True, return an analog filter, otherwise a digital filter is returned.

\(output\): {'ba', 'zpk', 'sos'}, optional

**buttord**\((wp, ws, gpass, gstop[, analog])\)

Butterworth filter order selection.

**cheby1**\((N, rp, Wn[, btype, analog, output])\)

Chebyshev type I digital and analog filter design.

**cheby2**\((N, rs, Wn[, btype, analog, output])\)

Chebyshev type II digital and analog filter design.

**cheb1ord**\((wp, ws, gpass, gstop[, analog])\)

Chebyshev type I filter order selection.

**cheb2ord**\((wp, ws, gpass, gstop[, analog])\)

Chebyshev type II filter order selection.

**ellip**\((N, rp, rs, Wn[, btype, analog, output])\)

Elliptic (Cauer) digital and analog filter design.

**ellipord**\((wp, ws, gpass, gstop[, analog])\)

Elliptic (Cauer) filter order selection.

**iirnotch**\((w0, Q)\)

Design second-order IIR notch digital filter.

**iirpeak**\((w0, Q)\)

Design second-order IIR peak (resonant) digital filter.

scipy.signal.butter \((N, Wn, btype='low', analog=False, output='ba')\)

Butterworth digital and analog filter design.

Design an Nth-order digital or analog Butterworth filter and return the filter coefficients.

**Parameters**

\(N\): int

The order of the filter.

\(Wn\): array_like

A scalar or length-2 sequence giving the critical frequencies. For a Butterworth filter, this is the point at which the gain drops to 1/sqrt(2) that of the passband (the “-3 dB point”). For digital filters, \(Wn\) is normalized from 0 to 1, where 1 is the Nyquist frequency, pi radians/sample. (\(Wn\) is thus in half-cycles / sample.) For analog filters, \(Wn\) is an angular frequency (e.g. rad/s).

\(btype\): {'lowpass', 'highpass', 'bandpass', 'bandstop'}, optional

The type of filter. Default is ‘lowpass’.

\(analog\): bool, optional

When True, return an analog filter, otherwise a digital filter is returned.

\(output\): {'ba', 'zpk', 'sos'}, optional
Type of output: numerator/denominator (‘ba’), pole-zero (‘zpk’), or second-order sections (‘sos’). Default is ‘ba’.

Returns

- **b, a**: ndarray, ndarray
  Numerator (b) and denominator (a) polynomials of the IIR filter. Only returned if `output='ba'`.

- **z, p, k**: ndarray, ndarray, float
  Zeros, poles, and system gain of the IIR filter transfer function. Only returned if `output='zpk'`.

- **sos**: ndarray
  Second-order sections representation of the IIR filter. Only returned if `output=='sos'`.

See also:

*buttord*, *buttap*

Notes

The Butterworth filter has maximally flat frequency response in the passband.

The 'sos' output parameter was added in 0.16.0.

Examples

Plot the filter’s frequency response, showing the critical points:

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> b, a = signal.butter(4, 100, 'low', analog=True)
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.title('Butterworth filter frequency response')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.axvline(100, color='green') # cutoff frequency
>>> plt.show()
```

![Butterworth filter frequency response](image)
scipy.signal.buttord(wp, ws, gpass, gstop, analog=False)

Butterworth filter order selection.

Return the order of the lowest order digital or analog Butterworth filter that loses no more than \( gpass \) dB in the passband and has at least \( gstop \) dB attenuation in the stopband.

Parameters

- **wp**, **ws**: float
  Passband and stopband edge frequencies. For digital filters, these are normalized from 0 to 1, where 1 is the Nyquist frequency, \( \pi \) radians/sample. (\( wp \) and \( ws \) are thus in half-cycles / sample.) For example:
  - Lowpass: \( wp = 0.2, ws = 0.3 \)
  - Bandpass: \( wp = [0.2, 0.5], ws = [0.1, 0.6] \)
  - Bandstop: \( wp = [0.1, 0.6], ws = [0.2, 0.5] \)
  For analog filters, \( wp \) and \( ws \) are angular frequencies (e.g. rad/s).

- **gpass**: float
  The maximum loss in the passband (dB).

- **gstop**: float
  The minimum attenuation in the stopband (dB).

- **analog**: bool, optional
  When True, return an analog filter, otherwise a digital filter is returned.

Returns

- **ord**: int
  The lowest order for a Butterworth filter which meets specs.

- **wn**: ndarray or float
  The Butterworth natural frequency (i.e. the “3dB frequency”). Should be used with butter to give filter results.

See also:

- butter
  Filter design using order and critical points

- cheb1ord, cheb2ord
  Find order and critical points from passband and stopband spec

- iirfilter
  General filter design using order and critical frequencies

- iirdesign
  General filter design using passband and stopband spec

Examples

Design an analog bandpass filter with passband within 3 dB from 20 to 50 rad/s, while rejecting at least -40 dB below 14 and above 60 rad/s. Plot its frequency response, showing the passband and stopband constraints in gray.

```python
>>> from scipy import signal
cp> import matplotlib.pyplot as plt

>>> N, Wn = signal.buttord([20, 50], [14, 60], 3, 40, True)
>>> b, a = signal.butter(N, Wn, 'band', True)
>>> w, h = signal.freqs(b, a, np.logspace(1, 2, 500))
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.title('Butterworth bandpass filter fit to constraints')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.grid(which='both', axis='both')
>>> plt.fill([1, 14, 14, 1], [-40, -40, 99, 99], '0.9', lw=0) # stop
>>> plt.fill([20, 20, 50, 50], [-99, -3, -3, -99], '0.9', lw=0) # pass
>>> plt.fill([60, 60, 1e9, 1e9], [99, -40, -40, 99], '0.9', lw=0) # stop
>>> plt.axis([10, 100, -60, 3])
>>> plt.show()
```
scipy.signal.cheby1 \((N, rp, Wn, btype='low', analog=False, output='ba')\)

Chebyshev type I digital and analog filter design.

Design an Nth-order digital or analog Chebyshev type I filter and return the filter coefficients.

**Parameters**

- \(N\) : int
  The order of the filter.
- \(rp\) : float
  The maximum ripple allowed below unity gain in the passband. Specified in decibels, as a positive number.
- \(Wn\) : array_like
  A scalar or length-2 sequence giving the critical frequencies. For Type I filters, this is the point in the transition band at which the gain first drops below \(-rp\). For digital filters, \(Wn\) is normalized from 0 to 1, where 1 is the Nyquist frequency, \(pi\) radians/sample. \((Wn\) is thus in half-cycles / sample.) For analog filters, \(Wn\) is an angular frequency (e.g. rad/s).
- \(btype\) : \{'lowpass', 'highpass', 'bandpass', 'bandstop'\}, optional
  The type of filter. Default is 'lowpass'.
- \(analog\) : bool, optional
  When True, return an analog filter, otherwise a digital filter is returned.
- \(output\) : \{'ba', 'zpk', 'sos'\}, optional
  Type of output: numerator/denominator ('ba'), pole-zero ('zpk'), or second-order sections ('sos'). Default is 'ba'.

**Returns**

- \(b, a\) : ndarray, ndarray
  Numerator \(b\) and denominator \(a\) polynomials of the IIR filter. Only returned if \(output == 'ba'\).
- \(z, p, k\) : ndarray, ndarray, float
  Zeros, poles, and system gain of the IIR filter transfer function. Only returned if \(output == 'zpk'\).
- \(sos\) : ndarray
  Second-order sections representation of the IIR filter. Only returned if \(output == 'sos'\).

**See also:**

cheb1ord, chebap
**Notes**

The Chebyshev type I filter maximizes the rate of cutoff between the frequency response’s passband and stopband, at the expense of ripple in the passband and increased ringing in the step response.

Type I filters roll off faster than Type II (`cheby2`), but Type II filters do not have any ripple in the passband.

The equiripple passband has N maxima or minima (for example, a 5th-order filter has 3 maxima and 2 minima). Consequently, the DC gain is unity for odd-order filters, or -rp dB for even-order filters.

The 'sos' output parameter was added in 0.16.0.

**Examples**

Plot the filter’s frequency response, showing the critical points:

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> b, a = signal.cheby1(4, 5, 100, 'low', analog=True)
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.title('Chebyshev Type I frequency response (rp=5)')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.axvline(100, color='green')  # cutoff frequency
>>> plt.axhline(-5, color='green')   # rp
>>> plt.show()
```

![Chebyshev Type I frequency response (rp=5)](image)

**scipy.signal.cheb1ord**(wp, ws, gpass, gstop, analog=False)

Chebyshev type I filter order selection.

Return the order of the lowest order digital or analog Chebyshev Type I filter that loses no more than `gpass` dB in the passband and has at least `gstop` dB attenuation in the stopband.

**Parameters**

- `wp, ws`: float
Passband and stopband edge frequencies. For digital filters, these are normalized from 0 to 1, where 1 is the Nyquist frequency, pi radians/sample. (wp and ws are thus in half-cycles / sample.) For example:

- Lowpass: \(wp = 0.2, ws = 0.3\)
- Highpass: \(wp = 0.3, ws = 0.2\)
- Bandpass: \(wp = [0.3, 0.5], ws = [0.1, 0.6]\)
- Bandstop: \(wp = [0.1, 0.6], ws = [0.2, 0.5]\)

For analog filters, \(wp\) and \(ws\) are angular frequencies (e.g. rad/s).

**gpass**: float
The maximum loss in the passband (dB).

**gstop**: float
The minimum attenuation in the stopband (dB).

**analog**: bool, optional
When True, return an analog filter, otherwise a digital filter is returned.

**Returns**

- **ord**: int
  The lowest order for a Chebyshev type I filter that meets specs.

- **wn**: ndarray or float
  The Chebyshev natural frequency (the “3dB frequency”) for use with `cheby1` to give filter results.

**See also:**

- `cheby1`
  Filter design using order and critical points
- `buttord`
  Find order and critical points from passband and stopband spec
- `cheb2ord`, `ellipord`
- `iirfilter`
  General filter design using order and critical frequencies
- `iirdesign`
  General filter design using passband and stopband spec

**Examples**

Design a digital lowpass filter such that the passband is within 3 dB up to 0.2*(fs/2), while rejecting at least -40 dB above 0.3*(fs/2). Plot its frequency response, showing the passband and stopband constraints in gray.

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> N, Wn = signal.cheby1ord(0.2, 0.3, 3, 40)
>>> b, a = signal.cheby1(N, 3, Wn, 'low')
>>> w, h = signal.freqz(b, a)
>>> plt.semilogx(w / np.pi, 20 * np.log10(abs(h)))
>>> plt.title('Chebyshev I lowpass filter fit to constraints')
>>> plt.xlabel('Normalized frequency')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.grid(which='both', axis='both')
>>> plt.fill([.01, 0.2, 0.2, .01], [-3, -3, -99, -99], '0.9', lw=0)  # stop
>>> plt.fill([0.3, 0.3, 2, 2], [ 9, -40, -40, 9], '0.9', lw=0)  # pass
>>> plt.axis([0.08, 1, -60, 3])
>>> plt.show()```
Design an Nth-order digital or analog Chebyshev type II filter and return the filter coefficients.

**Parameters**

- `N`: int
  - The order of the filter.
- `rs`: float
  - The minimum attenuation required in the stop band. Specified in decibels, as a positive number.
- `Wn`: array_like
  - A scalar or length-2 sequence giving the critical frequencies. For Type II filters, this is the point in the transition band at which the gain first reaches \(-rs\). For digital filters, `Wn` is normalized from 0 to 1, where 1 is the Nyquist frequency, pi radians/sample. (Wn is thus in half-cycles / sample.) For analog filters, `Wn` is an angular frequency (e.g. rad/s).
- `btype`: {'lowpass', 'highpass', 'bandpass', 'bandstop'}, optional
  - The type of filter. Default is ‘lowpass’.
- `analog`: bool, optional
  - When True, return an analog filter, otherwise a digital filter is returned.
- `output`: {'ba', 'zpk', 'sos'}, optional
  - Type of output: numerator/denominator (`'ba'`), pole-zero (`'zpk'`), or second-order sections (`'sos'`). Default is `'ba'`.

**Returns**

- `b, a`: ndarray, ndarray
  - Numerator (`b`) and denominator (`a`) polynomials of the IIR filter. Only returned if `output='ba'`.
- `z, p, k`: ndarray, ndarray, float
  - Zeros, poles, and system gain of the IIR filter transfer function. Only returned if `output='zpk'`.
- `sos`: ndarray
  - Second-order sections representation of the IIR filter. Only returned if `output=='sos'`.

**See also:**

- `cheb2ord`, `cheb2ap`
Notes

The Chebyshev type II filter maximizes the rate of cutoff between the frequency response’s passband and stopband, at the expense of ripple in the stopband and increased ringing in the step response.

Type II filters do not roll off as fast as Type I (cheby1).

The 'sos' output parameter was added in 0.16.0.

Examples

Plot the filter’s frequency response, showing the critical points:

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> b, a = signal.cheby2(4, 40, 100, 'low', analog=True)
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.title('Chebyshev Type II frequency response (rs=40)')
>>> plt.xlabel('Frequency [radians / second]

scipy.signal.cheb2ord(wp, ws, gpass, gstop, analog=False)

Chebyshev type II filter order selection.

Return the order of the lowest order digital or analog Chebyshev Type II filter that loses no more than gpass dB in the passband and has at least gstop dB attenuation in the stopband.

Parameters

wp, ws : float
    Passband and stopband edge frequencies. For digital filters, these are normalized from 0 to 1, where 1 is the Nyquist frequency, pi radians/sample. (wp and ws are thus in half-cycles / sample.) For example:
    * lowpass: wp = 0.2, ws = 0.3
    * highpass: wp = 0.3, ws = 0.2
Bandpass: \(wp = [0.2, 0.5] \), \(ws = [0.4, 0.6] \)

Bandstop: \(wp = [0.1, 0.6] \), \(ws = [0.2, 0.5] \)

For analog filters, \(wp\) and \(ws\) are angular frequencies (e.g. \text{rad/s}).

\[ \text{gpass}: \text{float} \]

The maximum loss in the passband (dB).

\[ \text{gstop}: \text{float} \]

The minimum attenuation in the stopband (dB).

\[ \text{analog}: \text{bool, optional} \]

When True, return an analog filter, otherwise a digital filter is returned.

\[ \text{ord}: \text{int} \]

The lowest order for a Chebyshev type II filter that meets specs.

\[ \text{wn}: \text{ndarray or float} \]

The Chebyshev natural frequency (the “3dB frequency”) for use with \text{cheby2} to give filter results.

\text{See also:}

\text{cheb1ord, ellipord}

\text{iirfilter} General filter design using order and critical frequencies

\text{iirdesign} General filter design using passband and stopband spec

\text{Examples}

Design a digital bandstop filter which rejects -60 dB from 0.2*(fs/2) to 0.5*(fs/2), while staying within 3 dB below 0.1*(fs/2) or above 0.6*(fs/2). Plot its frequency response, showing the passband and stopband constraints in gray.

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> N, Wn = signal.cheb2ord([0.1, 0.6], [0.2, 0.5], 3, 60)
>>> b, a = signal.cheby2(N, 60, Wn, 'stop')
>>> w, h = signal.freqz(b, a)
>>> plt.semilogx(w / np.pi, 20 * np.log10(abs(h)))
>>> plt.title('Chebyshev II bandstop filter fit to constraints')
>>> plt.xlabel('Normalized frequency')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.grid(which='both', axis='both')
>>> plt.fill([0.01, 0.1, 1, 1], [-3, -3, -99, -99], '0.9', lw=0) # stop
>>> plt.fill([0.2, 0.2, 0.5, 0.5], [-9, -60, -60, 9], '0.9', lw=0) # pass
>>> plt.fill([0.6, 0.6, 2, 2], [-99, -3, -3, -99], '0.9', lw=0) # stop
>>> plt.axis([0.06, 1, -80, 3])
>>> plt.show()
```
Design an Nth-order digital or analog elliptic filter and return the filter coefficients.

**Parameters**
- **N**: int
  - The order of the filter.
- **rp**: float
  - The maximum ripple allowed below unity gain in the passband. Specified in decibels, as a positive number.
- **rs**: float
  - The minimum attenuation required in the stop band. Specified in decibels, as a positive number.
- **Wn**: array_like
  - A scalar or length-2 sequence giving the critical frequencies. For elliptic filters, this is the point in the transition band at which the gain first drops below \(-rp\). For digital filters, \(Wn\) is normalized from 0 to 1, where 1 is the Nyquist frequency, \(\pi\) radians/sample. (\(Wn\) is thus in half-cycles / sample.) For analog filters, \(Wn\) is an angular frequency (e.g. rad/s).
- **btype**: {'lowpass', 'highpass', 'bandpass', 'bandstop'}, optional
  - The type of filter. Default is 'lowpass'.
- **analog**: bool, optional
  - When True, return an analog filter, otherwise a digital filter is returned.
- **output**: {'ba', 'zpk', 'sos'}, optional
  - Type of output: numerator/denominator ('ba'), pole-zero ('zpk'), or second-order sections ('sos'). Default is 'ba'.

**Returns**
- **b, a**: ndarray, ndarray
  - Numerator \((b)\) and denominator \((a)\) polynomials of the IIR filter. Only returned if \(\text{output}='ba'\).
- **z, p, k**: ndarray, ndarray, float
  - Zeros, poles, and system gain of the IIR filter transfer function. Only returned if \(\text{output}='zpk'\).
- **sos**: ndarray
  - Second-order sections representation of the IIR filter. Only returned if \(\text{output}='sos'\).

**See also:**

`scipy.signal.ellip(N, rp, rs, Wn, btype='low', analog=False, output='ba')`

Elliptic (Cauer) digital and analog filter design.
**ellipord, ellipap**

**Notes**

Also known as Cauer or Zolotarev filters, the elliptical filter maximizes the rate of transition between the frequency response’s passband and stopband, at the expense of ripple in both, and increased ringing in the step response.

As $rp$ approaches 0, the elliptical filter becomes a Chebyshev type II filter (cheby2). As $rs$ approaches 0, it becomes a Chebyshev type I filter (cheby1). As both approach 0, it becomes a Butterworth filter (butter).

The equiripple passband has $N$ maxima or minima (for example, a 5th-order filter has 3 maxima and 2 minima). Consequently, the DC gain is unity for odd-order filters, or $-rp$ dB for even-order filters.

The 'sos' output parameter was added in 0.16.0.

**Examples**

Plot the filter’s frequency response, showing the critical points:

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> b, a = signal.ellip(4, 5, 40, 100, 'low', analog=True)
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(abs(h))
>>> plt.title('Elliptic filter frequency response (rp=5, rs=40)')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.axvline(100, color='green')  # cutoff frequency
>>> plt.axhline(-40, color='green')  # rs
>>> plt.axhline(-5, color='green')  # rp
>>> plt.show()
```

![Elliptic filter frequency response (rp=5, rs=40)](image)

**scipy.signal.ellipord(wp, ws, gpass, gstop, analog=False)**

Elliptic (Cauer) filter order selection.
Return the order of the lowest order digital or analog elliptic filter that loses no more than $g_{\text{pass}}$ dB in the passband and has at least $g_{\text{stop}}$ dB attenuation in the stopband.

**Parameters**

- **wp, ws**: float
  - Passband and stopband edge frequencies. For digital filters, these are normalized from 0 to 1, where 1 is the Nyquist frequency, pi radians/sample. ($wp$ and $ws$ are thus in half-cycles / sample.) For example:
    - Lowpass: $wp = 0.2$, $ws = 0.3$
    - Highpass: $wp = 0.7$, $ws = 0.5$
    - Bandpass: $wp = [0.7, 0.5]$, $ws = [0.1, 0.6]$
    - Bandstop: $wp = [0.1, 0.6]$, $ws = [0.2, 0.5]$
  - For analog filters, $wp$ and $ws$ are angular frequencies (e.g. rad/s).

- **gpass**: float
  - The maximum loss in the passband (dB).

- **gstop**: float
  - The minimum attenuation in the stopband (dB).

- **analog**: bool, optional
  - When True, return an analog filter, otherwise a digital filter is returned.

**Returns**

- **ord**: int
  - The lowest order for an Elliptic (Cauer) filter that meets specs.

- **wn**: ndarray or float
  - The Chebyshev natural frequency (the “3dB frequency”) for use with `ellip` to give filter results.

See also:

- `ellip` Filter design using order and critical points
- `butter` Filter design using order and critical points from passband and stopband spec

- `cheb1ord`, `cheb2ord`
- `iirfilter` General filter design using order and critical frequencies
- `iirdesign` General filter design using passband and stopband spec

**Examples**

Design an analog highpass filter such that the passband is within 3 dB above 30 rad/s, while rejecting -60 dB at 10 rad/s. Plot its frequency response, showing the passband and stopband constraints in gray.

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> N, Wn = signal.ellipord(30, 10, 3, 60, True)
>>> b, a = signal.ellip(N, 3, 60, Wn, 'high', True)
>>> w, h = signal.freqs(b, a, np.logspace(0, 3, 500))
>>> plt.semilogx(w, 20 * np.log10(abs(h)))
>>> plt.title('Elliptical highpass filter fit to constraints')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.grid(which='both', axis='both')
>>> plt.fill([.1, 10, 10, .1], [1e4, 1e4, -60, -60], '0.9', lw=0)  # stop
>>> plt.fill([30, 30, 1e5, 1e9], [-99, -99, -3, -3], '0.9', lw=0)  # pass
>>> plt.axis([1, 300, -80, 3])
>>> plt.show()
```
scipy.signal.bessel\( (N, Wn, btype='low', analog=False, output='ba', norm='phase') \)

Bessel/Thomson digital and analog filter design.

Design an Nth-order digital or analog Bessel filter and return the filter coefficients.

**Parameters**

- \( N \): int
  - The order of the filter.
- \( Wn \): array_like
  - A scalar or length-2 sequence giving the critical frequencies (defined by the \( \text{norm} \) parameter). For analog filters, \( Wn \) is an angular frequency (e.g. rad/s). For digital filters, \( Wn \) is normalized from 0 to 1, where 1 is the Nyquist frequency, \( \pi \) radians/sample. \( (Wn \) is thus in half-cycles / sample.)
- \( btype \): \{'lowpass', 'highpass', 'bandpass', 'bandstop'\}, optional
  - The type of filter. Default is 'lowpass'.
- \( analog \): bool, optional
  - When True, return an analog filter, otherwise a digital filter is returned. (See Notes.)
- \( output \): \{'ba', 'zpk', 'sos'\}, optional
  - Type of output: numerator/denominator ('ba'), pole-zero ('zpk'), or second-order sections ('sos'). Default is 'ba'.
- \( norm \): \{'phase', 'delay', 'mag'\}, optional
  - Critical frequency normalization:
    - **phase**: The filter is normalized such that the phase response reaches its midpoint at angular (e.g. rad/s) frequency \( Wn \). This happens for both low-pass and high-pass filters, so this is the “phase-matched” case.
      - The magnitude response asymptotes are the same as a Butterworth filter of the same order with a cutoff of \( Wn \).
      - This is the default, and matches MATLAB’s implementation.
    - **delay**: The filter is normalized such that the group delay in the passband is \( 1/Wn \) (e.g. seconds). This is the “natural” type obtained by solving Bessel polynomials.
    - **mag**: The filter is normalized such that the gain magnitude is -3 dB at angular frequency \( Wn \).

**Returns**

- \( b, a \) : ndarray, ndarray
  - New in version 0.18.0.
Numerator \( (b) \) and denominator \( (a) \) polynomials of the IIR filter. Only returned if `output='ba'`.

\[ z, p, k : \text{ndarray, ndarray, float} \]

Zeros, poles, and system gain of the IIR filter transfer function. Only returned if `output='zpk'`.

\[ \text{sos : ndarray} \]

Second-order sections representation of the IIR filter. Only returned if `output=='sos'`.

**Notes**

Also known as a Thomson filter, the analog Bessel filter has maximally flat group delay and maximally linear phase response, with very little ringing in the step response. [R229]

The Bessel is inherently an analog filter. This function generates digital Bessel filters using the bilinear transform, which does not preserve the phase response of the analog filter. As such, it is only approximately correct at frequencies below about \( fs/4 \). To get maximally-flat group delay at higher frequencies, the analog Bessel filter must be transformed using phase-preserving techniques.

See `besselap` for implementation details and references.

The 'sos' output parameter was added in 0.16.0.

**References**

[R229]

**Examples**

Plot the phase-normalized frequency response, showing the relationship to the Butterworth’s cutoff frequency (green):

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> b, a = signal.butter(4, 100, 'low', analog=True)
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(np.abs(h)), color='silver', ls='dashed')
>>> b, a = signal.bessel(4, 100, 'low', analog=True, norm='phase')
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(np.abs(h)))
>>> plt.title('Bessel filter magnitude response (with Butterworth)')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.axvline(100, color='green')  # cutoff frequency
>>> plt.show()
```
Bessel filter magnitude response (with Butterworth)

and the phase midpoint:

```python
>>> plt.figure()
>>> plt.semilogx(w, np.unwrap(np.angle(h)))
>>> plt.axvline(100, color='green')  # cutoff frequency
>>> plt.axhline(-np.pi, color='red')  # phase midpoint
>>> plt.title('Bessel filter phase response')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Phase [radians]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.show()
```

Plot the magnitude-normalized frequency response, showing the -3 dB cutoff:

```python
>>> b, a = signal.bessel(3, 10, 'low', analog=True, norm='mag')
>>> w, h = signal.freqs(b, a)
>>> plt.semilogx(w, 20 * np.log10(np.abs(h)))
```
```python
>>> plt.axhline(-3, color='red')  # -3 dB magnitude
>>> plt.axvline(10, color='green')  # cutoff frequency
>>> plt.title('Magnitude-normalized Bessel filter frequency response')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Amplitude [dB]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.show()
```

Plot the delay-normalized filter, showing the maximally-flat group delay at 0.1 seconds:

```python
>>> b, a = signal.bessel(5, 1/0.1, 'low', analog=True, norm='delay')
>>> w, h = signal.freqs(b, a)
>>> plt.figure()
>>> plt.semilogx(w[1:], -np.diff(np.unwrap(np.angle(h)))/np.diff(w))
>>> plt.axhline(0.1, color='red')  # 0.1 seconds group delay
>>> plt.title('Bessel filter group delay')
>>> plt.xlabel('Frequency [radians / second]')
>>> plt.ylabel('Group delay [seconds]')
>>> plt.margins(0, 0.1)
>>> plt.grid(which='both', axis='both')
>>> plt.show()
```
scipy.signal.iirnotch(w0, Q)

Design second-order IIR notch digital filter.

A notch filter is a band-stop filter with a narrow bandwidth (high quality factor). It rejects a narrow frequency band and leaves the rest of the spectrum little changed.

**Parameters**

- **w0**: float
  Normalized frequency to remove from a signal. It is a scalar that must satisfy $0 < w0 < 1$, with $w0 = 1$ corresponding to half of the sampling frequency.

- **Q**: float
  Quality factor. Dimensionless parameter that characterizes notch filter -3 dB bandwidth $bw$ relative to its center frequency, $Q = w0/bw$.

**Returns**

- **b, a**: ndarray, ndarray
  Numerator (b) and denominator (a) polynomials of the IIR filter.

**See also:**

iirpeak

**Notes**

**References**

[R275]

**Examples**

Design and plot filter to remove the 60Hz component from a signal sampled at 200Hz, using a quality factor $Q = 30$

```python
>>> from scipy import signal
>>> import numpy as np
>>> import matplotlib.pyplot as plt

>>> fs = 200.0  # Sample frequency (Hz)
>>> f0 = 60.0  # Frequency to be removed from signal (Hz)
>>> Q = 30.0  # Quality factor
>>> w0 = f0/(fs/2)  # Normalized Frequency
```
Design notch filter

```python
>>> # Design notch filter
>>> b, a = signal.iirnotch(w0, Q)
```

```python
>>> # Frequency response
>>> w, h = signal.freqz(b, a)
>>> # Generate frequency axis
>>> freq = w*fs/(2*np.pi)
>>> # Plot
>>> fig, ax = plt.subplots(2, 1, figsize=(8, 6))
>>> ax[0].plot(freq, 20*np.log10(abs(h)), color='blue')
>>> ax[0].set_title("Frequency Response")
>>> ax[0].set_ylabel("Amplitude (dB)", color='blue')
>>> ax[0].set_xlim([0, 100])
>>> ax[0].set_ylim([-25, 10])
>>> ax[0].grid()
>>> ax[1].plot(freq, np.unwrap(np.angle(h))*180/np.pi, color='green')
>>> ax[1].set_ylabel("Angle (degrees)", color='green')
>>> ax[1].set_xlabel("Frequency (Hz)")
>>> ax[1].set_xlim([0, 100])
>>> ax[1].set_yticks([-90, -60, -30, 0, 30, 60, 90])
>>> ax[1].set_ylim([-90, 90])
>>> ax[1].grid()
>>> plt.show()
```

```python
scipy.signal.iirpeak(w0, Q)
```

Design second-order IIR peak (resonant) digital filter.
A peak filter is a band-pass filter with a narrow bandwidth (high quality factor). It rejects components outside a narrow frequency band.

**Parameters**
- **w0**: float
  - Normalized frequency to be retained in a signal. It is a scalar that must satisfy $0 < w0 < 1$, with $w0 = 1$ corresponding to half of the sampling frequency.
- **Q**: float
  - Quality factor. Dimensionless parameter that characterizes peak filter -3 dB bandwidth $bw$ relative to its center frequency, $Q = w0/bw$.

**Returns**
- **b, a**: ndarray, ndarray
  - Numerator ($b$) and denominator ($a$) polynomials of the IIR filter.

**See also:**
- iirnotch

**Notes**

**References**
- [R276]

**Examples**

Design and plot filter to remove the frequencies other than the 300Hz component from a signal sampled at 1000Hz, using a quality factor $Q = 30$

```
>>> from scipy import signal
>>> import numpy as np
>>> import matplotlib.pyplot as plt

>>> fs = 1000.0  # Sample frequency (Hz)
>>> f0 = 300.0   # Frequency to be retained (Hz)
>>> Q = 30.0    # Quality factor
>>> w0 = f0/(fs/2)  # Normalized Frequency

>>> # Design peak filter
>>> b, a = signal.iirpeak(w0, Q)

>>> # Frequency response
>>> w, h = signal.freqz(b, a)
>>> # Generate frequency axis
>>> freq = w*fs/(2*np.pi)

>>> # Plot
>>> fig, ax = plt.subplots(2, 1, figsize=(8, 6))
>>> ax[0].plot(freq, 20*np.log10(abs(h)), color='blue')
>>> ax[0].set_title("Frequency Response")
>>> ax[0].set_ylabel("Amplitude (dB)", color='blue')
>>> ax[0].set_xlim([0, 500])
>>> ax[0].set_ylim([-50, 10])
>>> ax[0].grid()
>>> ax[1].plot(freq, np.unwrap(np.angle(h))*180/np.pi, color='green')
>>> ax[1].set_ylabel("Angle (degrees)", color='green')
>>> ax[1].set_xlabel("Frequency (Hz)")
>>> ax[1].set_xlim([0, 500])
>>> ax[1].set_ylim([-90, 90])
>>> ax[1].grid()
>>> plt.show()
```

</tr>
</tbody>
</table>
class `scipy.signal.lti(*system)`

Continuous-time linear time invariant system base class.

**Parameters**

*system : arguments

The `lti` class can be instantiated with either 2, 3 or 4 arguments. The following gives the number of arguments and the corresponding continuous-time subclass that is created:

- **2**: `TransferFunction`: `(numerator, denominator)`
- **3**: `ZerosPolesGain`: `(zeros, poles, gain)`
- **4**: `StateSpace`: `(A, B, C, D)`

Each argument can be an array or a sequence.

**Notes**

`lti` instances do not exist directly. Instead, `lti` creates an instance of one of its subclasses: `StateSpace`, `TransferFunction`, or `ZerosPolesGain`.

If (numerator, denominator) is passed in for `*system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g., \( s^2 + 3s + 5 \) would be represented as \([1, 3, 5]\)).

Changing the value of properties that are not directly part of the current system representation (such as the zeros of a `StateSpace` system) is very inefficient and may lead to numerical inaccuracies. It is better to convert to the specific system representation first. For example, call `sys = sys.to_zpk()` before accessing/changing the zeros, poles or gain.

**Examples**

```python
>>> from scipy import signal

>>> signal.lti(1, 2, 3, 4)
StateSpaceContinuous(
array([[1]]),
array([[2]]),
array([[3]]),
array([[4]]),
dt: None)

>>> signal.lti([1, 2], [3, 4], 5)
ZerosPolesGainContinuous(
array([[1, 2]]),
array([[3, 4]]),
5,
dt: None)

>>> signal.lti([3, 4], [1, 2])
TransferFunctionContinuous(
array([[3, 4]]),
array([[1, 2]]),
dt: None)
```
Attributes
<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dt</td>
<td>Return the sampling time of the system, <em>None</em> for lti systems.</td>
</tr>
<tr>
<td>poles</td>
<td>Poles of the system.</td>
</tr>
<tr>
<td>zeros</td>
<td>Zeros of the system.</td>
</tr>
</tbody>
</table>

**lti.dt**
Return the sampling time of the system, *None* for lti systems.

**lti.poles**
Poles of the system.

**lti.zeros**
Zeros of the system.

**Methods**

**bode([w, n])**
Calculate Bode magnitude and phase data of a continuous-time system.

**freqresp([w, n])**
Calculate the frequency response of a continuous-time system.

**impulse([X0, T, N])**
Return the impulse response of a continuous-time system.

**output(U, T[, X0])**
Return the response of a continuous-time system to input $U$.

**step([X0, T, N])**
Return the step response of a continuous-time system.

**to_discrete(dt[, method, alpha])**
Return a discretized version of the current system.

**Examples**

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> sys = signal.TransferFunction([1], [1, 1])
>>> w, mag, phase = sys.bode()

>>> plt.figure()
>>> plt.semilogx(w, mag)  # Bode magnitude plot
>>> plt.figure()
>>> plt.semilogx(w, phase)  # Bode phase plot
>>> plt.show()
```
**lti.freqresp**(w=None, n=10000)

Calculate the frequency response of a continuous-time system.

Returns a 2-tuple containing arrays of frequencies [rad/s] and complex magnitude. See `freqresp` for details.

**lti.impulse**(X0=None, T=None, N=None)

Return the impulse response of a continuous-time system. See `impulse` for details.

**lti.output**(U, T, X0=None)

Return the response of a continuous-time system to input U. See `lsim` for details.

**lti.step**(X0=None, T=None, N=None)

Return the step response of a continuous-time system. See `step` for details.

**lti.to_discrete**(dt, method='zoh', alpha=None)

Return a discretized version of the current system.

Parameters: See `cont2discrete` for details.
Returns

sys: instance of dlti

class scipy.signal.StateSpace(*system, **kwargs)

Linear Time Invariant system in state-space form.

Represents the system as the continuous-time, first order differential equation $\dot{x} = Ax + Bu$ or the discrete-time difference equation $x[k+1] = Ax[k] + Bu[k]$. StateSpace systems inherit additional functionality from the lti, respectively the dlti classes, depending on which system representation is used.

Parameters

*system: arguments

The StateSpace class can be instantiated with 1 or 3 arguments. The following gives the number of input arguments and their interpretation:

•1: lti or dlti system: (StateSpace, TransferFunction or ZerosPolesGain)

•4: array_like: (A, B, C, D)

*system: arguments

The StateSpace class can be instantiated with 1 or 3 arguments. The following gives the number of input arguments and their interpretation:

•1: lti or dlti system: (StateSpace, TransferFunction or ZerosPolesGain)

•4: array_like: (A, B, C, D)

dt: float, optional

Sampling time [s] of the discrete-time systems. Defaults to None (continuous-time). Must be specified as a keyword argument, for example, dt=0.1.

See also:

TransferFunction, ZerosPolesGain, lti, dlti, ss2zpk, ss2tf, zpk2sos

Notes

Changing the value of properties that are not part of the StateSpace system representation (such as zeros or poles) is very inefficient and may lead to numerical inaccuracies. It is better to convert to the specific system representation first. For example, call sys = sys.to_zpk() before accessing/changing the zeros, poles or gain.

Examples

```python
>>> from scipy import signal

>>> a = np.array([[0, 1], [0, 0]])
>>> b = np.array([[0], [1]])
>>> c = np.array([[1, 0]])
>>> d = np.array([[0]])

>>> sys = signal.StateSpace(a, b, c, d)
>>> print(sys)
StateSpaceContinuous(
array([[0, 1],
       [0, 0]]),
array([[0],
       [1]]),
array([[1, 0]]),
array([[0]]),
dt: None)

>>> sys.to_discrete(0.1)
StateSpaceDiscrete(
array([[ 1. , 0.1],
       [ 0. , 1. ]]),
array([[ 0.005],
       [ 0.1 ]]),
array([[1, 0]]),
```
array([[0]]),
dt: 0.1)

```python
>>> a = np.array([[1, 0.1], [0, 1]])
>>> b = np.array([[0.005], [0.1]])

>>> signal.StateSpace(a, b, c, d, dt=0.1)
StateSpaceDiscrete(
    array([[ 1. , 0.1],
    [ 0. , 1. ]]),
    array([[ 0.005],
    [ 0.1 ]]),
    array([[1, 0]]),
    array([0]),
    dt: 0.1)
```

### Attributes

- **A**: State matrix of the `StateSpace` system.
- **B**: Input matrix of the `StateSpace` system.
- **C**: Output matrix of the `StateSpace` system.
- **D**: Feedthrough matrix of the `StateSpace` system.
- **dt**: Return the sampling time of the system, `None` for `lti` systems.
- **poles**: Poles of the system.
- **zeros**: Zeros of the system.

### Methods

- **to_ss()**: Return a copy of the current `StateSpace` system.
- **to_tf(**kwargs)**: Convert system representation to `TransferFunction`.

Continued on next page
Table 5.148 – continued from previous page

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>to_zpk(**kwargs)</td>
<td>Convert system representation to ZerosPolesGain.</td>
</tr>
</tbody>
</table>

```
StateSpace.to_ss()
    Return a copy of the current StateSpace system.

    Parameters
    sys : instance of StateSpace
    The current system (copy)

StateSpace.to_tf(**kwargs)
    Convert system representation to TransferFunction.

    Parameters
    kwargs : dict, optional
    Additional keywords passed to ss2zpk

    Returns
    sys : instance of TransferFunction
    Transfer function of the current system

StateSpace.to_zpk(**kwargs)
    Convert system representation to ZerosPolesGain.

    Parameters
    kwargs : dict, optional
    Additional keywords passed to ss2zpk

    Returns
    sys : instance of ZerosPolesGain
    Zeros, poles, gain representation of the current system

class scipy.signal.TransferFunction (*system, **kwargs)
    Linear Time Invariant system class in transfer function form.

    Represents the system as the continuous-time transfer function
    \( H(s) = \sum_{i=0}^{N} b[N - i]s^i / \sum_{j=0}^{M} a[M - j]s^j \)
    or the discrete-time transfer function
    \( H(z) = \sum_{i=0}^{N} b[N - i]z^i / \sum_{j=0}^{M} a[M - j]z^j \),
    where \( b \) are elements of the numerator \( \text{num} \), \( a \) are elements of the
denominator \( \text{den} \), and \( N = \text{len}(b) - 1, M = \text{len}(a) - 1 \).

    TransferFunction systems inherit additional functionality from the lti, respectively the
dlti classes, depending on which system representation is used.

    Parameters
    *system: arguments
    The TransferFunction class can be instantiated with 1 or 2 arguments.
    The following gives the number of input arguments and their interpretation:
    • 1: lti or dlti system: (StateSpace, TransferFunction or ZerosPolesGain)
    • 2: array_like: (numerator, denominator)

    dt: float, optional
    Sampling time [s] of the discrete-time systems. Defaults to None
    (continuous-time). Must be specified as a keyword argument, for example, dt=0.1.

See also:
ZerosPolesGain, StateSpace, lti, dlti, tf2ss, tf2zpk, tf2sos

Notes
Changing the value of properties that are not part of the TransferFunction system representation (such
as the A, B, C, D state-space matrices) is very inefficient and may lead to numerical inaccuracies. It is better
to convert to the specific system representation first. For example, call sys = sys.to_ss() before accessing/changing the A, B, C, D system matrices.

If (numerator, denominator) is passed in for *system, coefficients for both the numerator and denominator
should be specified in descending exponent order (e.g. \( s^2 + 3s + 5 \) or \( z^2 + 3z + 5 \) would be repre-
dented as [1, 3, 5])

5.20. Signal processing (scipy.signal)
Examples

Construct the transfer function:

\[ H(s) = \frac{s^2 + 3s + 3}{s^2 + 2s + 1} \]

```python
>>> from scipy import signal
```
```python
>>> num = [1, 3, 3]
>>> den = [1, 2, 1]
```

```python
>>> signal.TransferFunction(num, den)
```
```
TransferFunctionContinuous(array([ 1., 3., 3.]),
array([ 1., 2., 1.]),
dt: None)
```

Constrcut the transfer function with a sampling time of 0.1 seconds:

\[ H(z) = \frac{z^2 + 3z + 3}{z^2 + 2z + 1} \]

```python
>>> signal.TransferFunction(num, den, dt=0.1)
```
```
TransferFunctionDiscrete(array([ 1., 3., 3.]),
array([ 1., 2., 1.]),
dt: 0.1)
```

TransferFunction.den

Denominator of the TransferFunction system.

TransferFunction.dt

Return the sampling time of the system, None for lti systems.

TransferFunction.num

Numerator of the TransferFunction system.

TransferFunction.poles

Poles of the system.

TransferFunction.zeros

Zeros of the system.
Methods

5.20. Signal processing (scipy.signal)
```plaintext
>>> from scipy import signal
```

Transfer function: 

\[ H(s) = \frac{5(s - 1)(s - 2)}{(s - 3)(s - 4)} \]
>>> signal.ZerosPolesGain([1, 2], [3, 4], 5)
ZerosPolesGainContinuous(
  array([1, 2]),
  array([3, 4]),
  5,
  dt: None
)

Transfer function: \( H(z) = \frac{5(z - 1)(z - 2)}{(z - 3)(z - 4)} \)

```python
>>> signal.ZerosPolesGain([1, 2], [3, 4], 5, dt=0.1)
ZerosPolesGainDiscrete(
  array([1, 2]),
  array([3, 4]),
  5,
  dt: 0.1
)
```

\begin{verbatim}
ZerosPolesGain.to_ss()

Convert system representation to \texttt{StateSpace}.

\textbf{Returns}

- \texttt{sys}: instance of \texttt{StateSpace}
  State space model of the current system
\end{verbatim}

\begin{verbatim}
ZerosPolesGain.to_tf()

Convert system representation to \texttt{TransferFunction}.

\textbf{Returns}

- \texttt{sys}: instance of \texttt{TransferFunction}
  Transfer function of the current system
\end{verbatim}
ZerosPolesGain.to_zpk()

Return a copy of the current ‘ZerosPolesGain’ system.

Returns

sys : instance of ZerosPolesGain

The current system (copy)

scipy.signal.lsim(system, U, T, X0=None, interp=True)

Simulate output of a continuous-time linear system.

Parameters

system : an instance of the LTI class or a tuple describing the system.

The following gives the number of elements in the tuple and the interpreta-
ction:

• 1: (instance of lti)
• 2: (num, den)
• 3: (zeros, poles, gain)
• 4: (A, B, C, D)

U : array_like

An input array describing the input at each time T (interpolation is assumed
between given times). If there are multiple inputs, then each column of the
rank-2 array represents an input. If U = 0 or None, a zero input is used.

T : array_like

The time steps at which the input is defined and at which the output is
desired. Must be nonnegative, increasing, and equally spaced.

X0 : array_like, optional

The initial conditions on the state vector (zero by default).

interp : bool, optional

Whether to use linear (True, the default) or zero-order-hold (False) interpo-
lation for the input array.

Returns

T : 1D ndarray

Time values for the output.

yout : 1D ndarray

System response.

xout : ndarray

Time evolution of the state vector.

Notes

If (num, den) is passed in for system, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. \(s^2 + 3s + 5\) would be represented as \([1, 3, 5]\)).

Examples

Simulate a double integrator \(y'' = u\), with a constant input \(u = 1\)

```python
>>> from scipy import signal
>>> system = signal.lti([[0., 1.], [0., 0.]], [0.], [1., 0.], 0.)
>>> t = np.linspace(0, 5)
>>> u = np.ones_like(t)
>>> tout, y, x = signal.lsim(system, u, t)
>>> import matplotlib.pyplot as plt
>>> plt.plot(t, y)
```
`scipy.signal.lsim2(system, U=None, T=None, X0=None, **kwargs)`

Simulate output of a continuous-time linear system, by using the ODE solver `scipy.integrate.odeint`.

**Parameters**

- `system`: an instance of the `lti` class or a tuple describing the system.
  - The following gives the number of elements in the tuple and the interpretation:
    - 1: (instance of `lti`)
    - 2: (num, den)
    - 3: (zeros, poles, gain)
    - 4: (A, B, C, D)

- `U`: array_like (1D or 2D), optional
  - An input array describing the input at each time T. Linear interpolation is used between given times. If there are multiple inputs, then each column of the rank-2 array represents an input. If U is not given, the input is assumed to be zero.

- `T`: array_like (1D or 2D), optional
  - The time steps at which the input is defined and at which the output is desired. The default is 101 evenly spaced points on the interval [0,10.0].

- `X0`: array_like (1D), optional
  - The initial condition of the state vector. If X0 is not given, the initial conditions are assumed to be 0.

- `kwargs`: dict
  - Additional keyword arguments are passed on to the function `odeint`. See the notes below for more details.

**Returns**

- `T`: 1D ndarray
  - The time values for the output.

- `yout`: ndarray
  - The response of the system.

- `xout`: ndarray
  - The time-evolution of the state-vector.

**Notes**

This function uses `scipy.integrate.odeint` to solve the system’s differential equations. Additional keyword arguments given to `lsim2` are passed on to `odeint`. See the documentation for `scipy.integrate.odeint` for the full list of arguments.

If (num, den) is passed in for `system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. $s^2 + 3s + 5$ would be represented as $[1, 3, 5]$).
scipy.signal.impulse\( \text{system, } X0=\text{None, } T=\text{None, } N=\text{None} \)\n
Impulse response of continuous-time system.

**Parameters**

- **system**: an instance of the LTI class or a tuple of array_like describing the system. The following gives the number of elements in the tuple and the interpretation:
  - 1 (instance of lti)
  - 2 (num, den)
  - 3 (zeros, poles, gain)
  - 4 (A, B, C, D)

- **X0**: array_like, optional
  Initial state-vector. Defaults to zero.

- **T**: array_like, optional
  Time points.Computed if not given.

- **N**: int, optional
  The number of time points to compute (if T is not given).

**Returns**

- **T**: ndarray
  A 1-D array of time points.

- **yout**: ndarray
  A 1-D array containing the impulse response of the system (except for singularities at zero).

**Notes**

If (num, den) is passed in for system, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. \( s^2 + 3s + 5 \) would be represented as \([1, 3, 5]\)).

scipy.signal.impulse2\( \text{system, } X0=\text{None, } T=\text{None, } N=\text{None, } \text{**kwargs} \)\n
Impulse response of a single-input, continuous-time linear system.

**Parameters**

- **system**: an instance of the LTI class or a tuple of array_like describing the system. The following gives the number of elements in the tuple and the interpretation:
  - 1 (instance of lti)
  - 2 (num, den)
  - 3 (zeros, poles, gain)
  - 4 (A, B, C, D)

- **X0**: 1-D array_like, optional
  The initial condition of the state vector. Default: 0 (the zero vector).

- **T**: 1-D array_like, optional
  The time steps at which the input is defined and at which the output is desired. If T is not given, the function will generate a set of time samples automatically.

- **N**: int, optional
  Number of time points to compute. Default: 100.

- **kwargs**: various types
  Additional keyword arguments are passed on to the function scipy.signal.lsim2, which in turn passes them on to scipy.integrate.odeint; see the latter’s documentation for information about these arguments.

**Returns**

- **T**: ndarray
  The time values for the output.

- **yout**: ndarray
  The output response of the system.

**See also:**

impulse, lsim2, integrate.odeint
Notes

The solution is generated by calling `scipy.signal.lsim2`, which uses the differential equation solver `scipy.integrate.odeint`.

If (num, den) is passed in for `system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. \(s^2 + 3s + 5\) would be represented as \([1, 3, 5]\)).

New in version 0.8.0.

Examples

Second order system with a repeated root: \(x''(t) + 2x(t) + x(t) = u(t)\)

```python
>>> from scipy import signal
>>> system = ([1.0], [1.0, 2.0, 1.0])
>>> t, y = signal.impulse2(system)
>>> import matplotlib.pyplot as plt
>>> plt.plot(t, y)
```

`scipy.signal.step` (system, X0=None, T=None, N=None)
Step response of continuous-time system.

**Parameters**

- **system**: an instance of the LTI class or a tuple of array_like describing the system. The following gives the number of elements in the tuple and the interpretation:
  - 1 (instance of `lti`)
  - 2 (num, den)
  - 3 (zeros, poles, gain)
  - 4 (A, B, C, D)

- **X0**: array_like, optional
  Initial state-vector (default is zero).

- **T**: array_like, optional
  Time points (computed if not given).

- **N**: int, optional
  Number of time points to compute if \(T\) is not given.

**Returns**

- **T**: 1D ndarray
  Output time points.

- **yout**: 1D ndarray
  Step response of system.
See also:

scipy.signal.step2

Notes

If (num, den) is passed in for system, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. $s^2 + 3s + 5$ would be represented as [1, 3, 5]).

scipy.signal.step2(system, X0=None, T=None, N=None, **kwargs)

Step response of continuous-time system.

This function is functionally the same as scipy.signal.step, but it uses the function scipy.signal.lsim2 to compute the step response.

Parameters

system : an instance of the LTI class or a tuple of array_like
  describing the system. The following gives the number of elements in the
tuple and the interpretation:

  • 1 (instance of lti)
  • 2 (num, den)
  • 3 (zeros, poles, gain)

X0 : array_like, optional
  Initial state-vector (default is zero).

T : array_like, optional
  Time points (computed if not given).

N : int, optional
  Number of time points to compute if T is not given.

**kwargs : various types
  Additional keyword arguments are passed on the function scipy.signal.lsim2, which in turn passes them on to scipy.integrate.odeint. See the documentation for scipy.integrate.odeint for information about these arguments.

Returns

T : 1D ndarray
  Output time points.

yout : 1D ndarray
  Step response of system.

See also:

scipy.signal.step

Notes

If (num, den) is passed in for system, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. $s^2 + 3s + 5$ would be represented as [1, 3, 5]).

New in version 0.8.0.

scipy.signal.freqresp(system, w=None, n=10000)

Calculate the frequency response of a continuous-time system.

Parameters

system : an instance of the lti class or a tuple describing the system.

The following gives the number of elements in the tuple and the interpreta-
tion:

  • 1 (instance of lti)
  • 2 (num, den)
  • 3 (zeros, poles, gain)
  • 4 (A, B, C, D)

w : array_like, optional
  Array of frequencies (in rad/s). Magnitude and phase data is calculated for every value in this array. If not given, a reasonable set will be calculated.

n : int, optional
Number of frequency points to compute if $w$ is not given. The $n$ frequencies are logarithmically spaced in an interval chosen to include the influence of the poles and zeros of the system.

**Returns**
- $w$: 1D ndarray
  - Frequency array [rad/s]
- $H$: 1D ndarray
  - Array of complex magnitude values

**Notes**
If (num, den) is passed in for `system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. $s^2 + 3s + 5$ would be represented as $[1, 3, 5]$).

**Examples**
Generating the Nyquist plot of a transfer function

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

Transfer function: $H(s) = \frac{5}{(s-1)^3}$

```scipy.signal``.zerospolesgain([], [1, 1, 1], [5])

```>>>
>>> w, H = signal.freqresp(s1)

```>>>
>>> plt.figure()
>>> plt.plot(H.real, H.imag, "b")
>>> plt.plot(H.real, -H.imag, "r")
>>> plt.show()
```

```
scipy.signal.bode(system, w=None, n=100)
```
Calculate Bode magnitude and phase data of a continuous-time system.

**Parameters**
- `system`: an instance of the LTI class or a tuple describing the system.
  - The following gives the number of elements in the tuple and the interpretation:
    - $1$ (instance of `lti`)
w : array_like, optional
    Array of frequencies (in rad/s). Magnitude and phase data is calculated for
every value in this array. If not given a reasonable set will be calculated.

n : int, optional
    Number of frequency points to compute if w is not given. The n frequencies
are logarithmically spaced in an interval chosen to include the influence of
the poles and zeros of the system.

Returns

w : 1D ndarray
    Frequency array [rad/s]
mag : 1D ndarray
    Magnitude array [dB]
phase : 1D ndarray
    Phase array [deg]

Notes

If (num, den) is passed in for system, coefficients for both the numerator and denominator should be specified
in descending exponent order (e.g. \( s^2 + 3s + 5 \) would be represented as \([1, 3, 5]\)).

New in version 0.11.0.

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> sys = signal.TransferFunction([1], [1, 1])
>>> w, mag, phase = signal.bode(sys)

>>> plt.figure()
>>> plt.semilogx(w, mag)  # Bode magnitude plot
>>> plt.figure()
>>> plt.semilogx(w, phase)  # Bode phase plot
>>> plt.show()
```

![Bode magnitude and phase plots](image.png)
5.20.7 Discrete-Time Linear Systems

*dlti*(system, **kwargs) Discrete-time linear time invariant system base class.

*StateSpace*(system, **kwargs) Linear Time Invariant system in state-space form.

*TransferFunction*(system, **kwargs) Linear Time Invariant system class in transfer function form.

*ZerosPolesGain*(system, **kwargs) Linear Time Invariant system class in zeros, poles, gain form.

*dlsim*(system, u[, t, x0]) Simulate output of a discrete-time linear system.

*dimpulse*(system[, x0, t, n]) Impulse response of discrete-time system.

*dstep*(system[, x0, t, n]) Step response of discrete-time system.

*dfreqresp*(system[, w, n, whole]) Calculate the frequency response of a discrete-time system.

*dbode*(system[, w, n]) Calculate Bode magnitude and phase data of a discrete-time system.

**class** scipy.signal.dlti(*system, **kwargs)**

Discrete-time linear time invariant system base class.

**Parameters**

*system: arguments* The `dlti` class can be instantiated with either 2, 3 or 4 arguments. The following gives the number of arguments and the corresponding discrete-time subclass that is created:

1. `TransferFunction`: (numerator, denominator)
2. `ZerosPolesGain`: (zeros, poles, gain)
3. `StateSpace`: (A, B, C, D)

Each argument can be an array or a sequence.

**dt: float, optional**

Sampling time [s] of the discrete-time systems. Defaults to `True` (unspecified sampling time). Must be specified as a keyword argument, for example, `dt=0.1`.

**See also:**

ZerosPolesGain, StateSpace, TransferFunction, lti
Notes

dlti instances do not exist directly. Instead, dlti creates an instance of one of its subclasses: StateSpace,
TransferFunction or ZerosPolesGain.

Changing the value of properties that are not directly part of the current system representation (such as the
zeros of a StateSpace system) is very inefficient and may lead to numerical inaccuracies. It is better to
convert to the specific system representation first. For example, call sys = sys.to_zpk() before access-
ing/Changing the zeros, poles or gain.

If (numerator, denominator) is passed in for *system, coefficients for both the numerator and denominator
should be specified in descending exponent order (e.g., \( z^2 + 3z + 5 \) would be represented as \([1, 3, 5]\)).

New in version 0.18.0.

Examples

```python
>>> from scipy import signal

>>> signal.dlti(1, 2, 3, 4)
StateSpaceDiscrete(
    array([[1]]),
    array([[2]]),
    array([[3]]),
    array([[4]]),
    dt: True
)

>>> signal.dlti(1, 2, 3, 4, dt=0.1)
StateSpaceDiscrete(
    array([[1]]),
    array([[2]]),
    array([[3]]),
    array([[4]]),
    dt: 0.1
)

>>> signal.dlti([1, 2], [3, 4], 5, dt=0.1)
ZerosPolesGainDiscrete(
    array([1, 2]),
    array([3, 4]),
    5,
    dt: 0.1
)

>>> signal.dlti([3, 4], [1, 2], dt=0.1)
TransferFunctionDiscrete(
    array([ 3., 4.]),
    array([ 1., 2.]),
    dt: 0.1
)
```

Attributes

dt

Return the sampling time of the system.
Table 5.154 – continued from previous page

<table>

</tbody>
</table>

**dlti.bode (w=None, n=100)**

- Calculate Bode magnitude and phase data of a discrete-time system.
- Returns a 3-tuple containing arrays of frequencies [rad/s], magnitude [dB] and phase [deg]. See `dbode` for details.

**Examples**

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

Transfer function: H(z) = 1 / (z^2 + 2z + 3) with sampling time 0.5s

>>> sys = signal.TransferFunction([1], [1, 2, 3], dt=0.5)

Equivalent: `signal.dbode(sys)`
```
```python
>>> w, mag, phase = sys.bode()
```
```
>>> plt.figure()
>>> plt.semilogx(w, mag)  # Bode magnitude plot
>>> plt.figure()
>>> plt.semilogx(w, phase)  # Bode phase plot
>>> plt.show()
```

5.20. Signal processing (scipy.signal)
SciPy Reference Guide, Release 1.0.0

```python
dlti.freqresp(w=None, n=10000, whole=False)
    Calculate the frequency response of a discrete-time system.
    Returns a 2-tuple containing arrays of frequencies [rad/s] and complex magnitude. See dfreqresp for details.

dlti.impulse(x0=None, t=None, n=None)
    Return the impulse response of the discrete-time dlti system. See dimpulse for details.

dlti.output(u, t, x0=None)
    Return the response of the discrete-time system to input u. See dlsim for details.

dlti.step(x0=None, t=None, n=None)
    Return the step response of the discrete-time dlti system. See dstep for details.

scipy.signal.dlsim(system, u, t=None, x0=None)
    Simulate output of a discrete-time linear system.

    Parameters
    system : tuple of array_like or instance of dlti
```
A tuple describing the system. The following gives the number of elements in the tuple and the interpretation:

- 1: (instance of `dlti`
- 3: (num, den, dt)
- 4: (zeros, poles, gain, dt)
- 5: (A, B, C, D, dt)

\[ \text{u : array_like} \]

An input array describing the input at each time \( t \) (interpolation is assumed between given times). If there are multiple inputs, then each column of the rank-2 array represents an input.

\[ \text{t : array_like, optional} \]

The time steps at which the input is defined. If \( t \) is given, it must be the same length as \( u \), and the final value in \( t \) determines the number of steps returned in the output.

\[ \text{x0 : array_like, optional} \]

Initial conditions on the state vector (zero by default).

**Returns**

- `tout`: ndarray
  Time values for the output, as a 1-D array.
- `yout`: ndarray
  System response, as a 1-D array.
- `xout`: ndarray, optional
  Time-evolution of the state-vector. Only generated if the input is a `StateSpace` system.

**See also:**

`lsim`, `dstep`, `dimpulse`, `cont2discrete`

**Examples**

A simple integrator transfer function with a discrete time step of 1.0 could be implemented as:

```python
>>> from scipy import signal
>>> tf = ([1.0,], [1.0, -1.0], 1.0)
>>> t_in = [0.0, 1.0, 2.0, 3.0]
>>> u = np.asarray([0.0, 0.0, 1.0, 1.0])
>>> t_out, y = signal.dlsim(tf, u, t_in)
>>> y.T
array([[ 0., 0., 0., 1.]])
```

`scipy.signal.dimpulse` (system, x0=None, t=None, n=None)

Impulse response of discrete-time system.

**Parameters**

- `system`: tuple of array_like or instance of `dlti`
  A tuple describing the system. The following gives the number of elements in the tuple and the interpretation:
  - 1: (instance of `dlti`
  - 3: (num, den, dt)
  - 4: (zeros, poles, gain, dt)
  - 5: (A, B, C, D, dt)

- `x0`: array_like, optional
  Initial state-vector. Defaults to zero.

- `t`: array_like, optional
  Time points. Computed if not given.

- `n`: int, optional
  The number of time points to compute (if \( t \) is not given).

**Returns**

- `tout`: ndarray
  Time values for the output, as a 1-D array.

- `yout`: ndarray
  Impulse response of system. Each element of the tuple represents the output of the system based on an impulse in each input.
SciPy Reference Guide, Release 1.0.0

See also:

impulse, dstep, dlsim, cont2discrete

scipy.signal.dstep (system, x0=None, t=None, n=None)
Step response of discrete-time system.

Parameters

- **system**: tuple of array_like
  A tuple describing the system. The following gives the number of elements in the tuple and the interpretation:
  - 1: (instance of dlti)
  - 3: (num, den, dt)
  - 4: (zeros, poles, gain, dt)
  - 5: (A, B, C, D, dt)

- **x0**: array_like, optional
  Initial state-vector. Defaults to zero.

- **t**: array_like, optional
  Time points. Computed if not given.

- **n**: int, optional
  The number of time points to compute (if t is not given).

Returns

- **tout**: ndarray
  Output time points, as a 1-D array.

- **yout**: ndarray
  Step response of system. Each element of the tuple represents the output of the system based on a step response to each input.

See also:

step, dimpulse, dlsim, cont2discrete

scipy.signal.dfreqresp (system, w=None, n=10000, whole=False)
Calculate the frequency response of a discrete-time system.

Parameters

- **system**: an instance of the dlti class or a tuple describing the system.
  The following gives the number of elements in the tuple and the interpretation:
  - 1: (instance of dlti)
  - 2: (numerator, denominator, dt)
  - 4: (zeros, poles, gain, dt)
  - 5: (A, B, C, D, dt)

- **w**: array_like, optional
  Array of frequencies (in radians/sample). Magnitude and phase data is calculated for every value in this array. If not given a reasonable set will be calculated.

- **n**: int, optional
  Number of frequency points to compute if w is not given. The n frequencies are logarithmically spaced in an interval chosen to include the influence of the poles and zeros of the system.

- **whole**: bool, optional
  Normally, if ‘w’ is not given, frequencies are computed from 0 to the Nyquist frequency, pi radians/sample (upper-half of unit-circle). If whole is True, compute frequencies from 0 to 2*pi radians/sample.

Returns

- **w**: 1D ndarray
  Frequency array [radians/sample]

- **H**: 1D ndarray
  Array of complex magnitude values

Notes

If (num, den) is passed in for system, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. $z^2 + 3z + 5$ would be represented as [1, 3, 5]).
New in version 0.18.0.

**Examples**

Generating the Nyquist plot of a transfer function

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

Transfer function: \( H(z) = \frac{1}{z^2 + 2z + 3} \)

```  
```python
>>> sys = signal.TransferFunction([1], [1, 2, 3], dt=0.05)

```  
```python
>>> w, H = signal.dfreqresp(sys)

```  
```python
>>> plt.figure()
>>> plt.plot(H.real, H.imag, "b")
>>> plt.plot(H.real, -H.imag, "r")
>>> plt.show()
```

---

**scipy.signal.dbode** *(system, w=None, n=100)*

Calculate Bode magnitude and phase data of a discrete-time system.

**Parameters**

- **system**: an instance of the LTI class or a tuple describing the system.
  The following gives the number of elements in the tuple and the interpretation:
  - 1: instance of \( \texttt{dlti} \)
  - 2: \( \text{num, den, dt} \)
  - 3: \( \text{zeros, poles, gain, dt} \)
  - 4: \( \text{A, B, C, D, dt} \)

- **w**: array_like, optional
  Array of frequencies (in radians/sample). Magnitude and phase data is calculated for every value in this array. If not given a reasonable set will be calculated.

- **n**: int, optional
  Number of frequency points to compute if \( w \) is not given. The \( n \) frequencies are logarithmically spaced in an interval chosen to include the influence of the poles and zeros of the system.

**Returns**

- **w**: 1D ndarray
Frequency array [rad/time_unit]

**mag**: 1D ndarray
Magnitude array [dB]

**phase**: 1D ndarray
Phase array [deg]

**Notes**
If (num, den) is passed in for `system`, coefficients for both the numerator and denominator should be specified in descending exponent order (e.g. $z^2 + 3z + 5$ would be represented as $[1, 3, 5]$).

New in version 0.18.0.

**Examples**

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

Transfer function: $H(z) = 1 / (z^2 + 2z + 3)$

```python
>>> sys = signal.TransferFunction([1], [1, 2, 3], dt=0.05)
```...

Equivalent: `sys.bode()`

```python
>>> w, mag, phase = signal.dbode(sys)

```python
>>> plt.figure()
>>> plt.semilogx(w, mag)  # Bode magnitude plot
>>> plt.figure()
>>> plt.semilogx(w, phase)  # Bode phase plot
>>> plt.show()
```
5.20.8 LTI Representations

**tf2zpk**

Return zero, pole, gain \((z, p, k)\) representation from a numerator, denominator representation of a linear filter.

**tf2sos**

Return second-order sections from transfer function representation.

**tf2ss**

Transfer function to state-space representation.

**zpk2tf**

Return polynomial transfer function representation from zeros and poles.

**zpk2sos**

Return second-order sections from zeros, poles, and gain of a system.

**zpk2ss**

Zero-pole-gain representation to state-space representation.

**ss2tf**

State-space to transfer function.

**ss2zpk**

State-space representation to zero-pole-gain representation.

**sos2zpk**

Return zeros, poles, and gain of a series of second-order sections.

**sos2tf**

Return a single transfer function from a series of second-order sections.

**cont2discrete**

Transform a continuous to a discrete state-space system.

**place_poles**

Compute \(K\) such that eigenvalues \((A - \text{dot}(B, K))=\text{poles}\).

### scipy.signal.tf2zpk(b, a)

Return zero, pole, gain \((z, p, k)\) representation from a numerator, denominator representation of a linear filter.

**Parameters**

- **b**: array_like
  - Numerator polynomial coefficients.
- **a**: array_like
  - Denominator polynomial coefficients.

**Returns**

- **z**: ndarray
  - Zeros of the transfer function.
- **p**: ndarray
  - Poles of the transfer function.
\( k \) : float

System gain.

**Notes**

If some values of \( b \) are too close to 0, they are removed. In that case, a BadCoefficients warning is emitted.

The \( b \) and \( a \) arrays are interpreted as coefficients for positive, descending powers of the transfer function variable.

So the inputs \( b = [b_0, b_1, \ldots, b_M] \) and \( a = [a_0, a_1, \ldots, a_N] \) can represent an analog filter of the form:

\[
H(s) = \frac{b_0 s^M + b_1 s^{(M-1)} + \cdots + b_M}{a_0 s^N + a_1 s^{(N-1)} + \cdots + a_N}
\]

or a discrete-time filter of the form:

\[
H(z) = \frac{b_0 z^M + b_1 z^{(M-1)} + \cdots + b_M}{a_0 z^N + a_1 z^{(N-1)} + \cdots + a_N}
\]

This “positive powers” form is found more commonly in controls engineering. If \( M \) and \( N \) are equal (which is true for all filters generated by the bilinear transform), then this happens to be equivalent to the “negative powers” discrete-time form preferred in DSP:

\[
H(z) = \frac{b_0 + b_1 z^{-1} + \cdots + b_M z^{-M}}{a_0 + a_1 z^{-1} + \cdots + a_N z^{-N}}
\]

Although this is true for common filters, remember that this is not true in the general case. If \( M \) and \( N \) are not equal, the discrete-time transfer function coefficients must first be converted to the “positive powers” form before finding the poles and zeros.

**scipy.signal.tf2sos** \((b, a, \text{pairing=’nearest’})\)

Return second-order sections from transfer function representation

**Parameters**

- **b** : array_like
  Numerator polynomial coefficients.
- **a** : array_like
  Denominator polynomial coefficients.
- **pairing** : {‘nearest’, ‘keep_odd’}, optional
  The method to use to combine pairs of poles and zeros into sections. See \( \text{zpk2sos} \).

**Returns**

- **sos** : ndarray
  Array of second-order filter coefficients, with shape \((n\_sections, 6)\). See \( \text{sosfilt} \) for the SOS filter format specification.

**See also:**

\( \text{zpk2sos, sosfilt} \)

**Notes**

It is generally discouraged to convert from TF to SOS format, since doing so usually will not improve numerical precision errors. Instead, consider designing filters in ZPK format and converting directly to SOS. TF is converted to SOS by first converting to ZPK format, then converting ZPK to SOS.

New in version 0.16.0.

**scipy.signal.tf2ss** \((\text{num, den})\)

Transfer function to state-space representation

**Parameters**

- **num, den** : array_like
  Sequences representing the coefficients of the numerator and denominator polynomials, in order of descending degree. The denominator needs to be at least as long as the numerator.

**Returns**

- **A, B, C, D** : ndarray
  State space representation of the system, in controller canonical form.
Examples

Convert the transfer function:

$$H(s) = \frac{s^2 + 3s + 3}{s^2 + 2s + 1}$$

```python
>>> num = [1, 3, 3]
>>> den = [1, 2, 1]
```

to the state-space representation:

$$\begin{align*}
\dot{x}(t) &= \begin{bmatrix} -2 & -1 \\ 1 & 0 \end{bmatrix} x(t) + \begin{bmatrix} 1 \\ 0 \end{bmatrix} u(t) \\
y(t) &= \begin{bmatrix} 1 & 2 \end{bmatrix} x(t) + \begin{bmatrix} 1 \end{bmatrix} u(t)
\end{align*}$$

```python
>>> from scipy.signal import tf2ss
>>> A, B, C, D = tf2ss(num, den)
>>> A
array([[-2., -1.],
       [ 1.,  0.]])
>>> B
array([[1.],
       [0.]])
>>> C
array([[1., 2.]])
>>> D
array([[1.]])
```

\texttt{scipy.signal.zpk2tf}(z, p, k)

Return polynomial transfer function representation from zeros and poles

\textbf{Parameters}

- \texttt{z} : array_like
  Zeros of the transfer function.
- \texttt{p} : array_like
  Poles of the transfer function.
- \texttt{k} : float
  System gain.

\textbf{Returns}

- \texttt{b} : ndarray
  Numerator polynomial coefficients.
- \texttt{a} : ndarray
  Denominator polynomial coefficients.

\texttt{scipy.signal.zpk2sos}(z, p, k, pairing='nearest')

Return second-order sections from zeros, poles, and gain of a system

\textbf{Parameters}

- \texttt{z} : array_like
  Zeros of the transfer function.
- \texttt{p} : array_like
  Poles of the transfer function.
- \texttt{k} : float
  System gain.
- \texttt{pairing} : {'nearest', 'keep_odd'}, optional
  The method to use to combine pairs of poles and zeros into sections. See Notes below.

\textbf{Returns}

- \texttt{sos} : ndarray
  Second-order sections representation.
Array of second-order filter coefficients, with shape \((n_{\text{sections}}, 6)\). See \texttt{sosfilt}\ for the SOS filter format specification.

**See also:**

\texttt{sosfilt}

**Notes**

The algorithm used to convert ZPK to SOS format is designed to minimize errors due to numerical precision issues. The pairing algorithm attempts to minimize the peak gain of each biquadratic section. This is done by pairing poles with the nearest zeros, starting with the poles closest to the unit circle.

**Algorithms**

The current algorithms are designed specifically for use with digital filters. (The output coefficients are not correct for analog filters.)

The steps in the \texttt{pairing='nearest'} and \texttt{pairing='keep_odd'} algorithms are mostly shared. The \texttt{nearest} algorithm attempts to minimize the peak gain, while \texttt{'keep_odd'} minimizes peak gain under the constraint that odd-order systems should retain one section as first order. The algorithm steps and are as follows:

As a pre-processing step, add poles or zeros to the origin as necessary to obtain the same number of poles and zeros for pairing. If \texttt{pairing == 'nearest'} and there are an odd number of poles and a zero at the origin.

The following steps are then iterated over until no more poles or zeros remain:

1. Take the (next remaining) pole (complex or real) closest to the unit circle to begin a new filter section.
2. If the pole is real and there are no other remaining real poles\(^1\), add the closest real zero to the section and leave it as a first order section. Note that after this step we are guaranteed to be left with an even number of real poles, complex poles, real zeros, and complex zeros for subsequent pairing iterations.
3. Else:
   a. If the pole is complex and the zero is the only remaining real zero*, then pair the pole with the next closest zero (guaranteed to be complex). This is necessary to ensure that there will be a real zero remaining to eventually create a first-order section (thus keeping the odd order).
   b. Else pair the pole with the closest remaining zero (complex or real).
   c. Proceed to complete the second-order section by adding another pole and zero to the current pole and zero in the section:
      i. If the current pole and zero are both complex, add their conjugates.
      ii. Else if the pole is complex and the zero is real, add the conjugate pole and the next closest real zero.
      iii. Else if the pole is real and the zero is complex, add the conjugate zero and the real pole closest to those zeros.
      iv. Else (we must have a real pole and real zero) add the next real pole closest to the unit circle, and then add the real zero closest to that pole.

New in version 0.16.0.

**Examples**

Design a 6th order low-pass elliptic digital filter for a system with a sampling rate of 8000 Hz that has a pass-band corner frequency of 1000 Hz. The ripple in the pass-band should not exceed 0.087 dB, and the attenuation in the stop-band should be at least 90 dB.

In the following call to \texttt{signal.ellip}, we could use \texttt{output='sos'}, but for this example, we’ll use \texttt{output='zpk'}, and then convert to SOS format with \texttt{zpk2sos}:

```python
>>> from scipy import signal
>>> z, p, k = signal.ellip(6, 0.087, 90, 1000/(0.5*8000), output='zpk')
```

\(^1\) This conditional can only be met for specific odd-order inputs with the \texttt{pairing == 'keep_odd'} method.
Now convert to SOS format.

```python
>>> sos = signal.zpk2sos(z, p, k)
```

The coefficients of the numerators of the sections:

```python
>>> sos[:, :3]
array([[ 0.0014154 , 0.00248707, 0.0014154 ],
       [ 1. , 0.72965193, 1. ],
       [ 1. , 0.17594966, 1. ]])
```

The symmetry in the coefficients occurs because all the zeros are on the unit circle.

The coefficients of the denominators of the sections:

```python
>>> sos[:, 3:]
array([[ 1. , -1.32543251, 0.46989499],
       [ 1. , -1.26117915, 0.6262586 ],
       [ 1. , -1.25707217, 0.86199667]])
```

The next example shows the effect of the `pairing` option. We have a system with three poles and three zeros, so the SOS array will have shape (2, 6). The means there is, in effect, an extra pole and an extra zero at the origin in the SOS representation.

```python
>>> z1 = np.array([-1, -0.5-0.5j, -0.5+0.5j])
>>> p1 = np.array([0.75, 0.8+0.1j, 0.8-0.1j])
```

With `pairing='nearest'` (the default), we obtain

```python
>>> signal.zpk2sos(z1, p1, 1)
array([[ 1. , 1. , 0. , 1. , -0.75, 0. ],
       [ 1. , 1. , 0.5 , 1. , -1.6 , 0.65]])
```

The first section has the zeros {-0.5-0.05j, -0.5+0.5j} and the poles {0, 0.75}, and the second section has the zeros {-1, 0} and poles {0.8+0.1j, 0.8-0.1j}. Note that the extra pole and zero at the origin have been assigned to different sections.

With `pairing='keep_odd'`, we obtain:

```python
>>> signal.zpk2sos(z1, p1, 1, pairing='keep_odd')
array([[ 1. , 1. , 0. , 1. , -0.75, 0. ],
       [ 1. , 1. , 0.5 , 1. , -1.6 , 0.65]])
```

The extra pole and zero at the origin are in the same section. The first section is, in effect, a first-order section.

```python
scipy.signal.zpk2ss(z, p, k)
```

Zero-pole-gain representation to state-space representation

**Parameters**

- `z, p`: sequence
  - Zeros and poles.
- `k`: float
  - System gain.

**Returns**

- `A, B, C, D`: ndarray
  - State space representation of the system, in controller canonical form.

```python
scipy.signal.ss2tf(A, B, C, D, input=0)
```

State-space to transfer function.

A, B, C, D defines a linear state-space system with p inputs, q outputs, and n state variables.

**Parameters**

- `A`: array_like
State (or system) matrix of shape \((n, n)\)

\[ B : \text{array_like} \]

Input matrix of shape \((n, p)\)

\[ C : \text{array_like} \]

Output matrix of shape \((q, n)\)

\[ D : \text{array_like} \]

Feedthrough (or feedforward) matrix of shape \((q, p)\)

\[ \text{input} : \text{int, optional} \]

For multiple-input systems, the index of the input to use.

**Returns**

\[ \text{num} : \text{2-D ndarray} \]

Numerator(s) of the resulting transfer function(s). \(\text{num}\) has one row for each of the system’s outputs. Each row is a sequence representation of the numerator polynomial.

\[ \text{den} : \text{1-D ndarray} \]

Denominator of the resulting transfer function(s). \(\text{den}\) is a sequence representation of the denominator polynomial.

**Examples**

Convert the state-space representation:

\[
\begin{bmatrix}
-2 & -1 \\
1 & 0
\end{bmatrix}
\begin{bmatrix} x(t) \\ u(t) \end{bmatrix} +
\begin{bmatrix} 1 \\ 0 \end{bmatrix} u(t)
\]

\[
y(t) = \begin{bmatrix} 1 & 2 \end{bmatrix} x(t) + \begin{bmatrix} 1 \end{bmatrix} u(t)
\]

```python
>>> A = [[-2, -1], [1, 0]]
>>> B = [[[1]], [0]] # 2-dimensional column vector
>>> C = [[1], [2]] # 2-dimensional row vector
>>> D = 1
to the transfer function:

\[
H(s) = \frac{s^2 + 3s + 3}{s^2 + 2s + 1}
\]

```
scipy.signal.sos2zpk(sos)

Return zeros, poles, and gain of a series of second-order sections

Parameters

sos : array_like
    Array of second-order filter coefficients, must have shape
    (n_sections, 6). See sosfilt for the SOS filter format specification.

Returns

z : ndarray
    Zeros of the transfer function.

p : ndarray
    Poles of the transfer function.

k : float
    System gain.

Notes

New in version 0.16.0.

scipy.signal.sos2tf(sos)

Return a single transfer function from a series of second-order sections

Parameters

sos : array_like
    Array of second-order filter coefficients, must have shape
    (n_sections, 6). See sosfilt for the SOS filter format specification.

Returns

b : ndarray
    Numerator polynomial coefficients.

a : ndarray
    Denominator polynomial coefficients.

Notes

New in version 0.16.0.

scipy.signal.cont2discrete(system, dt, method='zoh', alpha=None)

Transform a continuous to a discrete state-space system.

Parameters

system : a tuple describing the system or an instance of lti
    The following gives the number of elements in the tuple and the interpreta-
    tion:
    
1: (instance of lti)
2: (num, den)
3: (zeros, poles, gain)
4: (A, B, C, D)

dt : float
    The discretization time step.

method : {'gbt', 'bilinear', 'euler', 'backward_diff', 'zoh'}, optional
    Which method to use:
    
• gbt: generalized bilinear transformation
• bilinear: Tustin's approximation (‘gbt’ with alpha=0.5)
• euler: Euler (or forward differencing) method (‘gbt’ with
  alpha=0)
• backward_diff: Backwards differencing (‘gbt’ with al-
  pha=1.0)
• zoh: zero-order hold (default)

alpha : float within [0, 1], optional
    The generalized bilinear transformation weighting parameter, which should
    only be specified with method='gbt', and is ignored otherwise

Returns

sysd : tuple containing the discrete system
    Based on the input type, the output will be of the form
    
• (num, den, dt) for transfer function input
• (zeros, poles, gain, dt) for zeros-poles-gain input

5.20. Signal processing (scipy.signal) 1203
SciPy Reference Guide, Release 1.0.0

•(A, B, C, D, dt) for state-space system input

Notes

By default, the routine uses a Zero-Order Hold (zoh) method to perform the transformation. Alternatively, a
generalized bilinear transformation may be used, which includes the common Tustin's bilinear approximation,
an Euler's method technique, or a backwards differencing technique.

The Zero-Order Hold (zoh) method is based on [R246], the generalized bilinear approximation is based on
[R247] and [R248].

References

[R246], [R247], [R248]

scipy.signal.place_poles (A, B, poles, method='YT', rtol=0.001, maxiter=30)
Compute K such that eigenvalues (A - dot(B, K))=poles.

K is the gain matrix such as the plant described by the linear system \(AX+BU\) will have its closed-loop poles, i.e
the eigenvalues \(A - B*K\), as close as possible to those asked for in poles.

SISO, MISO and MIMO systems are supported.

Parameters

A, B : ndarray
State-space representation of linear system \(AX + BU\).

poles : array_like
Desired real poles and/or complex conjugates poles. Complex poles are
only supported with method="YT" (default).

method: {'YT', 'KNV0'}, optional
Which method to choose to find the gain matrix K. One of:

• 'YT': Yang Tits
• 'KNV0': Kautsky, Nichols, Van Dooren update method 0

See References and Notes for details on the algorithms.

rtol: float, optional
After each iteration the determinant of the eigenvectors of \(A - B*K\) is
compared to its previous value, when the relative error between these two
values becomes lower than rtol the algorithm stops. Default is 1e-3.

maxiter: int, optional
Maximum number of iterations to compute the gain matrix. Default is 30.

Returns

full_state_feedback : Bunch object
full_state_feedback is composed of:

gain_matrix [1-D ndarray] The closed loop matrix K such
as the eigenvalues of \(A-BK\) are as close as
possible to the requested poles.

computed_poles [1-D ndarray] The poles corresponding to
\(A-BK\) sorted as first the real poles in increasing
order, then the complex conjugates in lexicographic order.

requested_poles [1-D ndarray] The poles the algorithm was
asked to place sorted as above, they may differ
from what was achieved.

X [2-D ndarray] The transfer matrix such as
\(X \times \text{diag} (\text{poles}) = (A - B*K) \times X\)
(see Notes)
rtol [float] The relative tolerance achieved on \( \det(X) \) (see Notes). \( rtol \) will be NaN if it is possible to solve the system \( \text{diag}(\text{poles}) = (A - B*K) \), or 0 when the optimization algorithms can't do anything i.e when \( B.\text{shape}[1] == 1 \).

nb_iter [int] The number of iterations performed before converging. \( nb\_\text{iter} \) will be NaN if it is possible to solve the system \( \text{diag}(\text{poles}) = (A - B*K) \), or 0 when the optimization algorithms can't do anything i.e when \( B.\text{shape}[1] == 1 \).

Notes

The Tits and Yang (YT), \([R295]\) paper is an update of the original Kautsky et al. (KNV) paper \([R294]\). KNV relies on rank-1 updates to find the transfer matrix \( X \) such that \( X \times \text{diag}(\text{poles}) = (A - B*K) \times X \), whereas YT uses rank-2 updates. This yields on average more robust solutions (see \([R295]\) pp 21-22), furthermore the YT algorithm supports complex poles whereas KNV does not in its original version. Only update method 0 proposed by KNV has been implemented here, hence the name 'KNV0'.

KNV extended to complex poles is used in Matlab's \texttt{place} function, YT is distributed under a non-free licence by Slicot under the name \texttt{robpole}. It is unclear and undocumented how KNV0 has been extended to complex poles (Tits and Yang claim on page 14 of their paper that their method can not be used to extend KNV to complex poles), therefore only YT supports them in this implementation.

As the solution to the problem of pole placement is not unique for MIMO systems, both methods start with a tentative transfer matrix which is altered in various way to increase its determinant. Both methods have been proven to converge to a stable solution, however depending on the way the initial transfer matrix is chosen they will converge to different solutions and therefore there is absolutely no guarantee that using 'KNV0' will yield results similar to Matlab's or any other implementation of these algorithms.

Using the default method 'YT' should be fine in most cases; 'KNV0' is only provided because it is needed by 'YT' in some specific cases. Furthermore 'YT' gives on average more robust results than 'KNV0' when \( \text{abs}(\det(X)) \) is used as a robustness indicator.

\([R295]\) is available as a technical report on the following URL: \texttt{http://drum.lib.umd.edu/handle/1903/5598}

References

\([R294]\), \([R295]\)

Examples

A simple example demonstrating real pole placement using both KNV and YT algorithms. This is example number 1 from section 4 of the reference KNV publication (\([R294]\)):

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> A = np.array([[ 1.380, -0.2077, 6.715, -5.676 ],
...                [-0.5814, -4.290, 0, 0.6750 ],
...                [ 1.067, 4.273, -6.654, 5.893 ],
...                [ 0.0480, 4.273, 1.343, -2.104 ]])
>>> B = np.array([[ 0, 5.679 ],
...                [ 1.136, 1.136 ],
...                [ 0, 0, 5.20 ]])
```
Now compute \( K \) with KNV method 0, with the default YT method and with the YT method while forcing 100 iterations of the algorithm and print some results after each call.

```python
>>> fsf1 = signal.place_poles(A, B, P, method='KNV0')
>>> fsf1.gain_matrix
array([[ 0.20071427, -0.96665799, 0.24066128, -0.10279785],
        [ 0.50587268,  0.57779091, 0.51795763, -0.41991442]])
```

```python
>>> fsf2 = signal.place_poles(A, B, P)  # uses YT method
>>> fsf2.computed_poles
array([-8.6659, -5.0566, -0.5 , -0.2 ])
```

```python
>>> fsf3 = signal.place_poles(A, B, P, rtol=-1, maxiter=100)
>>> fsf3.X
array([[-0.04977751+0.j, -0.80872954+0.j, 0.13566234+0.j, -0.29322906+0.j],
        [-0.82266932+0.j, -0.19168026+0.j, -0.56348322+0.j, -0.43815060+0.j],
        [ 0.22267347+0.j,  0.54967577+0.j, -0.58387806+0.j, -0.40271926+0.j]])
```

The absolute value of the determinant of \( X \) is a good indicator to check the robustness of the results, both 'KNV0' and 'YT' aim at maximizing it. Below a comparison of the robustness of the results above:

```python
>>> abs(np.linalg.det(fsf1.X)) < abs(np.linalg.det(fsf2.X))
True
>>> abs(np.linalg.det(fsf2.X)) < abs(np.linalg.det(fsf3.X))
True
```

Now a simple example for complex poles:

```python
>>> A = np.array([[ 0, 7/3., 0, 0 ],
                [ 0, 0, 0, 7/9. ],
                [ 0, 0, 0, 0 ],
                [ 0, 0, 0, 0 ]])
>>> B = np.array([[ 0, 0 ],
                [ 0, 0 ],
                [ 1, 0 ],
                [ 0, 1 ]])
>>> P = np.array([-3, -1, -2-1j, -2+1j]) / 3.
>>> fsf = signal.place_poles(A, B, P, method='YT')
```

We can plot the desired and computed poles in the complex plane:

```python
>>> t = np.linspace(0, 2*np.pi, 401)
>>> plt.plot(np.cos(t), np.sin(t), 'k--') # unit circle
>>> plt.plot(fsf.requested_poles.real, fsf.requested_poles.imag, 'wo', label='Desired')
>>> plt.plot(fsf.computed_poles.real, fsf.computed_poles.imag, 'bx', label='Placed')
>>> plt.grid()
>>> plt.axis('image')
>>> plt.axis([-1.1, 1.1, -1.1, 1.1])
>>> plt.legend(bbox_to_anchor=(1.05, 1), loc=2, numpoints=1)
```
5.20.9 Waveforms

```python
scipy.signal.chirp(t, f0, t1, f1[, method, phi, vertex_zero])
```

Frequency-swept cosine generator.

In the following, ‘Hz’ should be interpreted as ‘cycles per unit’; there is no requirement here that the unit is one second. The important distinction is that the units of rotation are cycles, not radians. Likewise, \( t \) could be a measurement of space instead of time.

**Parameters**

- **t** : array_like
  Times at which to evaluate the waveform.
- **f0** : float
  Frequency (e.g. Hz) at time \( t=0 \).
- **t1** : float
  Time at which \( f1 \) is specified.
- **f1** : float
  Frequency (e.g. Hz) of the waveform at time \( t1 \).
- **method** : {'linear', 'quadratic', 'logarithmic', 'hyperbolic'}, optional
  Kind of frequency sweep. If not given, \textit{linear} is assumed. See Notes below for more details.
- **phi** : float, optional
  Phase offset, in degrees. Default is 0.
- **vertex_zero** : bool, optional

```python
gausspulse(t[, fc, bw, bwr, tpr, retquad,...])
```

Return a Gaussian modulated sinusoid:

```python
max_len_seq(nbits[, state, length, taps])
```

Maximum length sequence (MLS) generator.

```python
sawtooth(t[, width])
```

Return a periodic sawtooth or triangle waveform.

```python
square(t[, duty])
```

Return a periodic square-wave waveform.

```python
sweep_poly(t, poly[, phi])
```

Frequency-swept cosine generator, with a time-dependent frequency.

```python
unit_impulse(shape[, idx, dtype])
```

Unit impulse signal (discrete delta function) or unit basis vector.

This parameter is only used when method is ‘quadratic’. It determines whether the vertex of the parabola that is the graph of the frequency is at t=0 or t=t1.

A numpy array containing the signal evaluated at t with the requested time-varying frequency. More precisely, the function returns \cos(\text{phase} + (\pi/180) \times \phi) where phase is the integral (from 0 to t) of 2\pi f(t). f(t) is defined below.

Returns

d : ndarray

A numpy array containing the signal evaluated at t with the requested time-varying frequency.

See also:

tune_poly

Notes

There are four options for the method. The following formulas give the instantaneous frequency (in Hz) of the signal generated by chirp(). For convenience, the shorter names shown below may also be used.

linear, lin, li:

\[ f(t) = f_0 + (f_1 - f_0) \times t / t_1 \]

quadratic, quad, q:

\[ f(t) = f_0 + (f_1 - f_0) \times t^2 / t_1^2 \]

To use a more general quadratic function, or an arbitrary polynomial, use the function scipy.signal.waveforms.sweep_poly.

logarithmic, log, lo:

\[ f(t) = f_0 \times (f_1 / f_0)^{(t/t_1)} \]

This signal is also known as a geometric or exponential chirp.

hyperbolic, hyp:

\[ f(t) = f_0 \times f_1 \times t_1 / ((f_0 - f_1) \times t + f_1 \times t_1) \]

For the first example, we’ll plot the waveform for a linear chirp from 6 Hz to 1 Hz over 10 seconds:

```python
from scipy.signal import chirp, spectrogram
import matplotlib.pyplot as plt

t = np.linspace(0, 10, 5001)
w = chirp(t, f0=6, f1=1, t1=10, method='linear')
plt.plot(t, w)
plt.title("Linear Chirp, f(0)=6, f(10)=1")
plt.xlabel('t (sec)')
plt.show()
```
For the remaining examples, we’ll use higher frequency ranges, and demonstrate the result using `scipy.signal.spectrogram`. We’ll use a 10 second interval sampled at 8000 Hz.

```python
>>> fs = 8000
>>> T = 10
>>> t = np.linspace(0, T, T*fs, endpoint=False)

Quadratic chirp from 1500 Hz to 250 Hz over 10 seconds (vertex of the parabolic curve of the frequency is at t=0):

```python
>>> w = chirp(t, f0=1500, f1=250, t1=10, method='quadratic')
>>> ff, tt, Sxx = spectrogram(w, fs=fs, noverlap=256, nperseg=512, nfft=2048)
>>> plt.pcolormesh(tt, ff[:513], Sxx[:513], cmap='gray_r')
>>> plt.title('Quadratic Chirp, f(0)=1500, f(10)=250')
>>> plt.xlabel('t (sec)')
>>> plt.ylabel('Frequency (Hz)')
>>> plt.grid()
>>> plt.show()
```
Quadratic chirp from 1500 Hz to 250 Hz over 10 seconds (vertex of the parabolic curve of the frequency is at t=10):

```python
>>> t = np.linspace(0, 10, 1000)
>>> frq = np.linspace(1500, 250, 1000)
>>> w = chirp(t, f0=1500, f1=250, t1=10, method='quadratic',
           vertex_zero=False)
>>> ff, tt, Sxx = spectrogram(w, fs=fs, noverlap=256, nperseg=512,
                           nfft=2048)
>>> plt.pcolormesh(tt, ff[:513], Sxx[:513], cmap='gray_r')
>>> plt.title('Quadratic Chirp, f(0)=2500, f(10)=250
(' +
             'vertex_zero=False')
>>> plt.xlabel('t (sec)')
>>> plt.ylabel('Frequency (Hz)')
>>> plt.grid()
>>> plt.show()
```

Logarithmic chirp from 1500 Hz to 250 Hz over 10 seconds:
Hyperbolic chirp from 1500 Hz to 250 Hz over 10 seconds:

```python
>>> w = chirp(t, f0=1500, f1=250, t1=10, method='hyperbolic')
>>> ff, tt, Sxx = spectrogram(w, fs=fs, noverlap=256, nperseg=512,
...                      nfft=2048)
>>> plt.pcolormesh(tt, ff[:513], Sxx[:513], cmap='gray_r')
>>> plt.title('Hyperbolic Chirp, f(0)=1500, f(10)=250')
>>> plt.xlabel('t (sec)')
>>> plt.ylabel('Frequency (Hz)')
>>> plt.grid()
>>> plt.show()
```
The function `scipy.signal.gausspulse` returns a Gaussian modulated sinusoid:

\[ \exp(-a t^2) \exp(1j \times 2\pi \times fc \times t) \]

If `retquad` is True, then return the real and imaginary parts (in-phase and quadrature). If `retenv` is True, then return the envelope (unmodulated signal). Otherwise, return the real part of the modulated sinusoid.

**Parameters**
- `t`: ndarray or the string ‘cutoff’
  - Input array.
- `fc`: int, optional
  - Center frequency (e.g. Hz). Default is 1000.
- `bw`: float, optional
  - Fractional bandwidth in frequency domain of pulse (e.g. Hz). Default is 0.5.
- `bwr`: float, optional
  - Reference level at which fractional bandwidth is calculated (dB). Default is -6.
- `tpr`: float, optional
  - If `t` is ‘cutoff’, then the function returns the cutoff time for when the pulse amplitude falls below `tpr` (in dB). Default is -60.
- `retquad`: bool, optional
  - If True, return the quadrature (imaginary) as well as the real part of the signal. Default is False.
- `retenv`: bool, optional
  - If True, return the envelope of the signal. Default is False.

**Returns**
- `yI`: ndarray
  - Real part of signal. Always returned.
- `yQ`: ndarray
  - Imaginary part of signal. Only returned if `retquad` is True.
- `yenv`: ndarray
  - Envelope of signal. Only returned if `retenv` is True.

**See also:**
- `scipy.signal.morlet`
Examples

Plot real component, imaginary component, and envelope for a 5 Hz pulse, sampled at 100 Hz for 2 seconds:

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> t = np.linspace(-1, 1, 2 * 100, endpoint=False)
>>> i, q, e = signal.gausspulse(t, fc=5, retquad=True, retenv=True)
>>> plt.plot(t, i, t, q, t, e, '--')
```

```
scipy.signal.max_len_seq(nbits, state=None, length=None, taps=None)

Maximum length sequence (MLS) generator.

Parameters
nbits : int
    Number of bits to use. Length of the resulting sequence will be
    \(2^{\text{nbits}} - 1\). Note that generating long sequences (e.g.,
    greater than \text{nbits} == 16) can take a long time.

state : array_like, optional
    If array, must be of length nbits, and will be cast to binary (bool)
    representation. If None, a seed of ones will be used, producing a
    repeatable representation. If state is all zeros, an error is raised as
    this is invalid. Default: None.

length : int, optional
    Number of samples to compute. If None, the entire length
    \(2^{\text{nbits}} - 1\) is computed.

taps : array_like, optional
    Polynomial taps to use (e.g., [7, 6, 1] for an 8-bit sequence). If None,
    taps will be automatically selected (for up to \text{nbits} == 32).

Returns
seq : array
    Resulting MLS sequence of 0’s and 1’s.

state : array
    The final state of the shift register.

Notes
The algorithm for MLS generation is generically described in:

https://en.wikipedia.org/wiki/Maximum_length_sequence
```
The default values for taps are specifically taken from the first option listed for each value of nbits in:

http://www.newwaveinstruments.com/resources/articles/m_sequence_linear_feedback_shift_register_lfsr.htm

New in version 0.15.0.

**Examples**

MLS uses binary convention:

```python
>>> from scipy.signal import max_len_seq
>>> max_len_seq(4)[0]
array([1, 1, 1, 1, 0, 1, 0, 1, 1, 0, 0, 1, 0, 0, 0], dtype=int8)
```

MLS has a white spectrum (except for DC):

```python
>>> from numpy.fft import fft, ifft, fftshift, fftfreq
>>> seq = max_len_seq(6)[0]*2-1  # +1 and -1
>>> spec = fft(seq)
>>> N = len(seq)
>>> plt.plot(fftshift(fftfreq(N)), fftshift(np.abs(spec)), '.-')
>>> plt.margins(0.1, 0.1)
>>> plt.grid(True)
>>> plt.show()
```

![Circular autocorrelation of MLS is an impulse](image_url)

Circular autocorrelation of MLS is an impulse:

```python
>>> acorrcirc = ifft(spec * np.conj(spec)).real
>>> plt.figure()
>>> plt.plot(np.arange(-N/2+1, N/2+1), fftshift(acorrcirc), '.-')
>>> plt.margins(0.1, 0.1)
>>> plt.grid(True)
>>> plt.show()
```
Linear autocorrelation of MLS is approximately an impulse:

```python
>>> acorr = np.correlate(seq, seq, 'full')
>>> plt.figure()
>>> plt.plot(np.arange(-N+1, N), acorr, '.-')
>>> plt.margins(0.1, 0.1)
>>> plt.grid(True)
>>> plt.show()
```

```
scipy.signal.sawtooth(t, width=1)
```

Return a periodic sawtooth or triangle waveform.

The sawtooth waveform has a period 2*pi, rises from -1 to 1 on the interval 0 to width*2*pi, then drops from 1 to -1 on the interval width*2*pi to 2*pi. width must be in the interval [0, 1].

Note that this is not band-limited. It produces an infinite number of harmonics, which are aliased back and forth across the frequency spectrum.

**Parameters**

- `t`: array_like
Time.

width : array_like, optional
Width of the rising ramp as a proportion of the total cycle. Default is 1, producing a rising ramp, while 0 produces a falling ramp. width = 0.5 produces a triangle wave. If an array, causes wave shape to change over time, and must be the same length as t.

Returns

y : ndarray
Output array containing the sawtooth waveform.

Examples

A 5 Hz waveform sampled at 500 Hz for 1 second:

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> t = np.linspace(0, 1, 500)
>>> plt.plot(t, signal.sawtooth(2 * np.pi * 5 * t))
```

scipy.signal.square(t, duty=0.5)

Return a periodic square-wave waveform.

The square wave has a period 2*\(\pi\), has value +1 from 0 to 2*\(\pi\)*duty and -1 from 2*\(\pi\)*duty to 2*\(\pi\). duty must be in the interval [0,1].

Note that this is not band-limited. It produces an infinite number of harmonics, which are aliased back and forth across the frequency spectrum.

Parameters
t : array_like
The input time array.

 duty : array_like, optional
Duty cycle. Default is 0.5 (50% duty cycle). If an array, causes wave shape to change over time, and must be the same length as t.

Returns

y : ndarray
Output array containing the square waveform.

Examples

A 5 Hz waveform sampled at 500 Hz for 1 second:
```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> t = np.linspace(0, 1, 500, endpoint=False)
>>> plt.plot(t, signal.square(2 * np.pi * 5 * t))
>>> plt.ylim(-2, 2)
```

A pulse-width modulated sine wave:

```python
>>> plt.figure()
>>> sig = np.sin(2 * np.pi * t)
>>> pwm = signal.square(2 * np.pi * 30 * t, duty=(sig + 1)/2)
>>> plt.plot(t, sig)
>>> plt.subplot(2, 1, 2)
>>> plt.plot(t, pwm)
>>> plt.ylim(-1.5, 1.5)
```

![Pulse-width modulated sine wave](image)

5.20. Signal processing (scipy.signal) 1217
scipy.signal.sweep_poly(t, poly, phi=0)
Frequency-swept cosine generator, with a time-dependent frequency.

This function generates a sinusoidal function whose instantaneous frequency varies with time. The frequency at time t is given by the polynomial poly.

Parameters

- **t**: ndarray
  Times at which to evaluate the waveform.
- **poly**: 1-D array_like or instance of numpy.poly1d
  The desired frequency expressed as a polynomial. If poly is a list or ndarray of length n, then the elements of poly are the coefficients of the polynomial, and the instantaneous frequency is:
  \[ f(t) = poly[0]*t^{(n-1)} + poly[1]*t^{(n-2)} + ... + poly[n-1] \]
  If poly is an instance of numpy.poly1d, then the instantaneous frequency is:
  \[ f(t) = poly(t) \]
- **phi**: float, optional
  Phase offset, in degrees, Default: 0.

Returns

- **sweep_poly**: ndarray
  A numpy array containing the signal evaluated at t with the requested time-varying frequency. More precisely, the function returns \( \cos(\text{phase} + (\pi/180) \times \phi) \), where phase is the integral (from 0 to t) of \( 2 \times \pi \times f(t) \); f(t) is defined above.

See also:

- chirp

Notes

New in version 0.8.0.

If poly is a list or ndarray of length n, then the elements of poly are the coefficients of the polynomial, and the instantaneous frequency is:

\[ f(t) = poly[0]*t^{(n-1)} + poly[1]*t^{(n-2)} + ... + poly[n-1] \]

If poly is an instance of numpy.poly1d, then the instantaneous frequency is:

\[ f(t) = poly(t) \]

Finally, the output s is:

\[ \cos(\text{phase} + (\pi/180) \times \phi) \]

where phase is the integral from 0 to t of \( 2 \times \pi \times f(t) \); f(t) as defined above.

Examples

Compute the waveform with instantaneous frequency:

\[ f(t) = 0.025*t^3 - 0.36*t^2 + 1.25*t + 2 \]

over the interval 0 <= t <= 10.

```python
>>> from scipy.signal import sweep_poly
>>> p = np.poly1d([0.025, -0.36, 1.25, 2.0])
>>> t = np.linspace(0, 10, 5001)
>>> w = sweep_poly(t, p)
```

Plot it:
```python
>>> import matplotlib.pyplot as plt
>>> plt.subplot(2, 1, 1)
>>> plt.plot(t, w)
>>> plt.title("Sweep Poly

with frequency \( f(t) = 0.025t^3 - 0.36t^2 + 1.25t + 2 \)")
>>> plt.subplot(2, 1, 2)
>>> plt.plot(t, p(t), 'r', label='f(t)')
>>> plt.legend()
>>> plt.xlabel('t')
>>> plt.tight_layout()
>>> plt.show()
```

**scipy.signal.unit_impulse** *(shape, idx=None, dtype=<type 'float'>)*

Unit impulse signal (discrete delta function) or unit basis vector.

**Parameters**

- **shape**: int or tuple of int
  Number of samples in the output (1-D), or a tuple that represents the shape of the output (N-D).
- **idx**: None or int or tuple of int or 'mid', optional
  Index at which the value is 1. If None, defaults to the 0th element. If idx='mid', the impulse will be centered at shape // 2 in all dimensions. If an int, the impulse will be at idx in all dimensions.
- **dtype**: data-type, optional
  The desired data-type for the array, e.g., numpy.int8. Default is numpy.float64.

**Returns**

- **y**: ndarray
  Output array containing an impulse signal.

**Notes**

The 1D case is also known as the Kronecker delta.

New in version 0.19.0.

**Examples**

An impulse at the 0th element (\( \delta[n] \)): 

```python
```
>>> from scipy import signal
>>> signal.unit_impulse(8)
array([ 1., 0., 0., 0., 0., 0., 0., 0.])

Impulse offset by 2 samples ($\delta[n - 2]$):

>>> signal.unit_impulse(7, 2)
array([ 0., 0., 1., 0., 0., 0., 0.])

2-dimensional impulse, centered:

>>> signal.unit_impulse((3, 3), 'mid')
array([[ 0., 0., 0.],
       [ 0., 1., 0.],
       [ 0., 0., 0.]])

Impulse at (2, 2), using broadcasting:

>>> signal.unit_impulse((4, 4), 2)
array([[ 0., 0., 0., 0.],
       [ 0., 0., 0., 0.],
       [ 0., 0., 1., 0.],
       [ 0., 0., 0., 0.]])

Plot the impulse response of a 4th-order Butterworth lowpass filter:

>>> imp = signal.unit_impulse(100, 'mid')
>>> b, a = signal.butter(4, 0.2)
>>> response = signal.lfilter(b, a, imp)

>>> import matplotlib.pyplot as plt
>>> plt.plot(np.arange(-50, 50), imp)
>>> plt.plot(np.arange(-50, 50), response)
>>> plt.margins(0.1, 0.1)
>>> plt.xlabel('Time [samples]')
>>> plt.ylabel('Amplitude')
>>> plt.grid(True)
>>> plt.show()
5.20.10 Window functions

```python
scipy.signal.get_window(window, Nx[, fftbins])
Return a window.

Parameters

window : string, float, or tuple
    The type of window to create. See below for more details.
```

**Example**

```python
scipy.signal.get_window('hann', 51)
```

Return a Hann window.

**Parameters**

- **window**: string, float, or tuple
  - The type of window to create. See below for more details.
**get_window** : ndarray
Returns a window of length \( N_x \) and type \( \text{window} \)

**Notes**
Window types:

- boxcar,
- triang,
- blackman,
- hamming,
- hann,
- bartlett,
- flattop,
- parzen,
- bohman,
- blackmanharris,
- nuttall,
- barthann,
- kaiser (needs beta),
- gaussian (needs standard deviation),
- general_gaussian (needs power, width),
- slepian (needs width),
- chebwin (needs attenuation),
- exponential (needs decay scale),
- tukey (needs taper fraction)

If the window requires no parameters, then \( \text{window} \) can be a string.

If the window requires parameters, then \( \text{window} \) must be a tuple with the first argument the string name of the window, and the next arguments the needed parameters.

If \( \text{window} \) is a floating point number, it is interpreted as the beta parameter of the \( \text{kaiser} \) window.

Each of the window types listed above is also the name of a function that can be called directly to create a window of that type.

**Examples**

```python
>>> from scipy import signal
>>> signal.get_window('triang', 7)
array([0.125, 0.375, 0.625, 0.875, 0.875, 0.625, 0.375])
>>> signal.get_window(('kaiser', 4.0), 9)
array([0.08848053, 0.29425961, 0.56437221, 0.82160913, 0.97885093,
       0.97885093, 0.82160913, 0.56437221, 0.29425961])
>>> signal.get_window(4.0, 9)
array([0.08848053, 0.29425961, 0.56437221, 0.82160913, 0.97885093,
       0.97885093, 0.82160913, 0.56437221, 0.29425961])
```

**scipy.signal.barthann** (\( M, \text{sym=True} \))
Return a modified Bartlett-Hann window.

**Parameters**

\( M \) : int
Number of points in the output window. If zero or less, an empty array is returned.

\( \text{sym} \) : bool, optional
When True (default), generates a symmetric window, for use in filter design. When False, generates a periodic window, for use in spectral analysis.

**Returns**

\( w \) : ndarray
The window, with the maximum value normalized to 1 (though the value 1 does not appear if \( M \) is even and \( \text{sym} \) is True).

**Examples**

Plot the window and its frequency response:

```python
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt
```
```python
>>> window = signal.barthann(51)
>>> plt.plot(window)
>>> plt.title("Bartlett-Hann window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")

>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the Bartlett-Hann window")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```

**Bartlett-Hann window**

![Bartlett-Hann window](image)

**Frequency response of the Bartlett-Hann window**

![Frequency response of the Bartlett-Hann window](image)

`scipy.signal.bartlett(M, sym=True)`

5.20. Signal processing (`scipy.signal`)
Return a Bartlett window.

The Bartlett window is very similar to a triangular window, except that the end points are at zero. It is often used in signal processing for tapering a signal, without generating too much ripple in the frequency domain.

Parameters

- **M** : int
  Number of points in the output window. If zero or less, an empty array is returned.

- **sym** : bool, optional
  When True (default), generates a symmetric window, for use in filter design. When False, generates a periodic window, for use in spectral analysis.

Returns

- **w** : ndarray
  The triangular window, with the first and last samples equal to zero and the maximum value normalized to 1 (though the value 1 does not appear if \( M \) is even and \( sym \) is True).

See also:

- **triang**
  A triangular window that does not touch zero at the ends

Notes

The Bartlett window is defined as

\[
w(n) = \frac{2}{M-1} \left( \frac{M-1}{2} - \left| n - \frac{M-1}{2} \right| \right)
\]

Most references to the Bartlett window come from the signal processing literature, where it is used as one of many windowing functions for smoothing values. Note that convolution with this window produces linear interpolation. It is also known as an apodization (which means "removing the foot", i.e. smoothing discontinuities at the beginning and end of the sampled signal) or tapering function. The Fourier transform of the Bartlett is the product of two sinc functions. Note the excellent discussion in Kanasewich. [R225]

References

[R224], [R225], [R226], [R227], [R228]

Examples

Plot the window and its frequency response:

```python
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt
>>> window = signal.bartlett(51)
>>> plt.plot(window)
>>> plt.title("Bartlett window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")

>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the Bartlett window")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```
scipy.signal.blackman \((M, \text{sym=True})\)

Return a Blackman window.

The Blackman window is a taper formed by using the first three terms of a summation of cosines. It was designed to have close to the minimal leakage possible. It is close to optimal, only slightly worse than a Kaiser window.

**Parameters**

- **M**: int
  Number of points in the output window. If zero or less, an empty array is returned.

- **sym**: bool, optional
  When True (default), generates a symmetric window, for use in filter design. When False, generates a periodic window, for use in spectral analysis.

**Returns**

- **w**: ndarray
  The window, with the maximum value normalized to 1 (though the value 1 does not appear if \(M\) is even and \(sym\) is True).
The Blackman window is defined as
\[
    w(n) = 0.42 - 0.5 \cos(2\pi n/M) + 0.08 \cos(4\pi n/M)
\]
The “exact Blackman” window was designed to null out the third and fourth sidelobes, but has discontinuities at the boundaries, resulting in a 6 dB/oct fall-off. This window is an approximation of the “exact” window, which does not null the sidelobes as well, but is smooth at the edges, improving the fall-off rate to 18 dB/oct. \[R238\]

Most references to the Blackman window come from the signal processing literature, where it is used as one of many windowing functions for smoothing values. It is also known as an apodization (which means “removing the foot”, i.e. smoothing discontinuities at the beginning and end of the sampled signal) or tapering function. It is known as a “near optimal” tapering function, almost as good (by some measures) as the Kaiser window.

References
\[R236\], \[R237\], \[R238\]

Examples
Plot the window and its frequency response:

```python
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt

>>> window = signal.blackman(51)
>>> plt.plot(window)
>>> plt.title("Blackman window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")

>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the Blackman window")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```
scipy.signal.blackmanharris($M$, $sym=True$)

Return a minimum 4-term Blackman-Harris window.

**Parameters**
- $M$ : int
  Number of points in the output window. If zero or less, an empty array is returned.
- $sym$ : bool, optional
  When True (default), generates a symmetric window, for use in filter design. When False, generates a periodic window, for use in spectral analysis.

**Returns**
- $w$ : ndarray
  The window, with the maximum value normalized to 1 (though the value 1 does not appear if $M$ is even and $sym$ is True).

**Examples**
Plot the window and its frequency response:
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt

>>> window = signal.blackmanharris(51)
>>> plt.plot(window)
>>> plt.title("Blackman-Harris window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")

>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the Blackman-Harris window")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
scipy.signal.bohman(M, sym=True)

Return a Bohman window.

**Parameters**

- `M` : int
  - Number of points in the output window. If zero or less, an empty array is returned.

- `sym` : bool, optional
  - When True (default), generates a symmetric window, for use in filter design.
  - When False, generates a periodic window, for use in spectral analysis.

**Returns**

- `w` : ndarray
  - The window, with the maximum value normalized to 1 (though the value 1 does not appear if `M` is even and `sym` is True).

**Examples**

Plot the window and its frequency response:

```python
code
from scipy import signal
from scipy.fftpack import fft, fftshift
import matplotlib.pyplot as plt

window = signal.bohman(51)
plt.plot(window)
plt.title("Bohman window")
plt.ylabel("Amplitude")
plt.xlabel("Sample")

plt.figure()
A = fft(window, 2048) / (len(window)/2.0)
freq = np.linspace(-0.5, 0.5, len(A))
response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
plt.plot(freq, response)
plt.axis([-0.5, 0.5, -120, 0])
plt.title("Frequency response of the Bohman window")
plt.ylabel("Normalized magnitude [dB]")
plt.xlabel("Normalized frequency [cycles per sample]")
```

5.20. Signal processing (scipy.signal) 1229
scipy.signal.boxcar(M, sym=True)

Return a boxcar or rectangular window.

Also known as a rectangular window or Dirichlet window, this is equivalent to no window at all.

Parameters

- **M** : int
  Number of points in the output window. If zero or less, an empty array is returned.

- **sym** : bool, optional
  Whether the window is symmetric. (Has no effect for boxcar.)

Returns

- **w** : ndarray
  The window, with the maximum value normalized to 1.

Examples

Plot the window and its frequency response:

```python
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
```
```python
>>> import matplotlib.pyplot as plt

>>> window = signal.boxcar(51)
>>> plt.plot(window)
>>> plt.title("Boxcar window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")

>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the boxcar window")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```

5.20. Signal processing (scipy.signal)
scipy.signal.chebwin(M, at, sym=True)

Return a Dolph-Chebyshev window.

Parameters

- **M**: int
  Number of points in the output window. If zero or less, an empty array is returned.

- **at**: float
  Attenuation (in dB).

- **sym**: bool, optional
  When True (default), generates a symmetric window, for use in filter design. When False, generates a periodic window, for use in spectral analysis.

Returns

- **w**: ndarray
  The window, with the maximum value always normalized to 1

Notes

This window optimizes for the narrowest main lobe width for a given order M and sidelobe equiripple attenuation at, using Chebyshev polynomials. It was originally developed by Dolph to optimize the directionality of radio antenna arrays.

Unlike most windows, the Dolph-Chebyshev is defined in terms of its frequency response:

\[
W(k) = \frac{\cos(M \cos^{-1}[\beta \cos(k/M)])}{\cosh[M \cosh^{-1}(\beta)]}
\]

where

\[
\beta = \cosh\left[\frac{1}{M} \cosh^{-1}(10^{\frac{A}{20}})\right]
\]

and \(0 \leq \text{abs}(k) \leq M-1\). A is the attenuation in decibels \((at)\).

The time domain window is then generated using the IFFT, so power-of-two \(M\) are the fastest to generate, and prime number \(M\) are the slowest.

The equiripple condition in the frequency domain creates impulses in the time domain, which appear at the ends of the window.

References

[R239], [R240], [R241]
Examples

Plot the window and its frequency response:

```python
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt

>>> window = signal.chebwin(51, at=100)
>>> plt.plot(window)
>>> plt.title("Dolph-Chebyshev window (100 dB)")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")

>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the Dolph-Chebyshev window (100 dB)")
>>> plt.ylabel("Normalized magnitude \([\text{dB}]\)")
>>> plt.xlabel("Normalized frequency \([\text{cycles per sample}]\)"
```

![Dolph-Chebyshev window (100 dB)](image)
scipy.signal.cosine(M, sym=True)

Return a window with a simple cosine shape.

**Parameters**

- **M**: int
  Number of points in the output window. If zero or less, an empty array is returned.

- **sym**: bool, optional
  When True (default), generates a symmetric window, for use in filter design.
  When False, generates a periodic window, for use in spectral analysis.

**Returns**

- **w**: ndarray
  The window, with the maximum value normalized to 1 (though the value 1 does not appear if M is even and sym is True).

**Notes**

New in version 0.13.0.

**Examples**

Plot the window and its frequency response:

```python
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt

>>> window = signal.cosine(51)
>>> plt.plot(window)
>>> plt.title("Cosine window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")

>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))

>>> plt.figure()
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the cosine window")
```
```python
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
>>> plt.show()
```

![Cosine window](image1)

![Frequency response of the cosine window](image2)

**scipy.signal.exponential** *(M, center=None, tau=1.0, sym=True)*  
Return an exponential (or Poisson) window.

**Parameters**  

- **M**: int  
  Number of points in the output window. If zero or less, an empty array is returned.

- **center**: float, optional  
  Parameter defining the center location of the window function. The default value if not given is \( \text{center} = (M-1) / 2 \). This parameter must take its default value for symmetric windows.

- **tau**: float, optional  
  Parameter defining the decay. For \( \text{center} = 0 \) use \( \text{tau} = -(M-1) / \ln(x) \) if \( x \) is the fraction of the window remaining at the end.
sym : bool, optional

When True (default), generates a symmetric window, for use in filter design.
When False, generates a periodic window, for use in spectral analysis.

Returns

w : ndarray

The window, with the maximum value normalized to 1 (though the value 1
does not appear if $M$ is even and $sym$ is True).

Notes

The Exponential window is defined as

$$w(n) = e^{-|n-center|/\tau}$$

References

Examples

Plot the symmetric window and its frequency response:

```python
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt

>>> M = 51
>>> tau = 3.0
>>> window = signal.exponential(M, tau=tau)
>>> plt.plot(window)
>>> plt.title("Exponential Window (tau=3.0")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")

>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -35, 0])
>>> plt.title("Frequency response of the Exponential window (tau=3.0")
>>> plt.ylabel("Normalized magnitude [dB"]
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```

This function can also generate non-symmetric windows:

```python
>>> tau2 = -(M-1) / np.log(0.01)
>>> window2 = signal.exponential(M, 0, tau2, False)
>>> plt.figure()
>>> plt.plot(window2)
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")
```
Exponential Window (tau=3.0)

Frequency response of the Exponential window (tau=3.0)
scipy.signal.flattop(M, sym=True)

Return a flat top window.

Parameters

M : int
Number of points in the output window. If zero or less, an empty array is returned.

sym : bool, optional
When True (default), generates a symmetric window, for use in filter design. When False, generates a periodic window, for use in spectral analysis.

Returns

w : ndarray
The window, with the maximum value normalized to 1 (though the value 1 does not appear if M is even and sym is True).

Notes

Flat top windows are used for taking accurate measurements of signal amplitude in the frequency domain, with minimal scalloping error from the center of a frequency bin to its edges, compared to others. This is a 5th-order cosine window, with the 5 terms optimized to make the main lobe maximally flat. [R257]

References

[R257]

Examples

Plot the window and its frequency response:

```python
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt

>>> window = signal.flattop(51)
>>> plt.plot(window)
>>> plt.title("Flat top window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")
```
```python
>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the flat top window")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```

scipy.signal.gaussian(M, std, sym=True)

Return a Gaussian window.

Parameters

- **M**: int
  - Number of points in the output window. If zero or less, an empty array is returned.

- **std**: float
The standard deviation, sigma.

**sym**: bool, optional
   When True (default), generates a symmetric window, for use in filter design. When False, generates a periodic window, for use in spectral analysis.

**Returns**

**w**: ndarray
   The window, with the maximum value normalized to 1 (though the value 1 does not appear if \( M \) is even and \( \text{sym} \) is True).

**Notes**

The Gaussian window is defined as

\[
   w(n) = e^{-\frac{1}{2}(\frac{n}{\sigma})^2}
\]

**Examples**

Plot the window and its frequency response:

```python
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt

>>> window = signal.gaussian(51, std=7)
>>> plt.plot(window)
>>> plt.title(r"Gaussian window ($\sigma=7$)"")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")

>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title(r"Frequency response of the Gaussian window ($\sigma=7$)"")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]"")
```

![Gaussian window (σ=7)](image-url)
scipy.signal.general_gaussian(M, p, sig, sym=True)

Return a window with a generalized Gaussian shape.

**Parameters**

- **M**: int
  Number of points in the output window. If zero or less, an empty array is returned.

- **p**: float
  Shape parameter. p = 1 is identical to `gaussian`, p = 0.5 is the same shape as the Laplace distribution.

- **sig**: float
  The standard deviation, sigma.

- **sym**: bool, optional
  When True (default), generates a symmetric window, for use in filter design. When False, generates a periodic window, for use in spectral analysis.

**Returns**

- **w**: ndarray
  The window, with the maximum value normalized to 1 (though the value 1 does not appear if M is even and sym is True).

**Notes**

The generalized Gaussian window is defined as

\[ w(n) = e^{-\frac{1}{2} \left| \frac{n}{\sigma} \right|^{2p}} \]

the half-power point is at

\[ (2 \log(2))^{1/(2p)} \sigma \]

**Examples**

Plot the window and its frequency response:

```python
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt
```
>>> window = signal.general_gaussian(51, p=1.5, sig=7)
>>> plt.plot(window)
>>> plt.title(r"Generalized Gaussian window (p=1.5, $\sigma$=7)")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")

>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title(r"Freq. resp. of the gen. Gaussian window (p=1.5, $\sigma$=7)")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]"")
scipy.signal.hamming(M, sym=True)

Return a Hamming window.

The Hamming window is a taper formed by using a raised cosine with non-zero endpoints, optimized to minimize the nearest side lobe.

**Parameters**
- **M**: int
  Number of points in the output window. If zero or less, an empty array is returned.
- **sym**: bool, optional
  When True (default), generates a symmetric window, for use in filter design. When False, generates a periodic window, for use in spectral analysis.

**Returns**
- **w**: ndarray
  The window, with the maximum value normalized to 1 (though the value 1 does not appear if M is even and sym is True).

**Notes**

The Hamming window is defined as

\[ w(n) = 0.54 - 0.46 \cos \left( \frac{2\pi n}{M - 1} \right) \quad 0 \leq n \leq M - 1 \]

The Hamming was named for R. W. Hamming, an associate of J. W. Tukey and is described in Blackman and Tukey. It was recommended for smoothing the truncated autocovariance function in the time domain. Most references to the Hamming window come from the signal processing literature, where it is used as one of many windowing functions for smoothing values. It is also known as an apodization (which means “removing the foot”, i.e. smoothing discontinuities at the beginning and end of the sampled signal) or tapering function.

**References**

[R259], [R260], [R261], [R262]

**Examples**

Plot the window and its frequency response:

```python
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt

>>> window = signal.hamming(51)
>>> plt.plot(window)
>>> plt.title("Hamming window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")

>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the Hamming window")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```
The Hann window is a taper formed by using a raised cosine or sine-squared with ends that touch zero.

**Parameters**

- **M**: int
  - Number of points in the output window. If zero or less, an empty array is returned.
  - **sym**: bool, optional
    - When True (default), generates a symmetric window, for use in filter design.
    - When False, generates a periodic window, for use in spectral analysis.

**Returns**

- **w**: ndarray
  - The window, with the maximum value normalized to 1 (though the value 1 does not appear if M is even and sym is True).

```python
scipy.signal.hann(M, sym=True)
```

Return a Hann window.
Notes

The Hann window is defined as

\[ w(n) = 0.5 - 0.5 \cos \left( \frac{2\pi n}{M-1} \right) \quad 0 \leq n \leq M - 1 \]

The window was named for Julius von Hann, an Austrian meteorologist. It is also known as the Cosine Bell. It is sometimes erroneously referred to as the “Hanning” window, from the use of “hann” as a verb in the original paper and confusion with the very similar Hamming window.

Most references to the Hann window come from the signal processing literature, where it is used as one of many windowing functions for smoothing values. It is also known as an apodization (which means “removing the foot”, i.e. smoothing discontinuities at the beginning and end of the sampled signal) or tapering function.

References

Examples

Plot the window and its frequency response:

```python
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt

>>> window = signal.hann(51)
>>> plt.plot(window)
>>> plt.title("Hann window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")

>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the Hann window")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```
scipy.signal.hanning(M, sym=True)

Return a Hann window.

The Hann window is a taper formed by using a raised cosine or sine-squared with ends that touch zero.

Parameters

- **M**: int
  Number of points in the output window. If zero or less, an empty array is returned.

- **sym**: bool, optional
  When True (default), generates a symmetric window, for use in filter design. When False, generates a periodic window, for use in spectral analysis.

Returns

- **w**: ndarray
  The window, with the maximum value normalized to 1 (though the value 1 does not appear if \( M \) is even and \( \text{sym} \) is True).
Notes

The Hann window is defined as

\[ w(n) = 0.5 - 0.5 \cos \left( \frac{2\pi n}{M - 1} \right) \quad 0 \leq n \leq M - 1 \]

The window was named for Julius von Hann, an Austrian meteorologist. It is also known as the Cosine Bell. It is sometimes erroneously referred to as the “Hanning” window, from the use of “hann” as a verb in the original paper and confusion with the very similar Hamming window.

Most references to the Hann window come from the signal processing literature, where it is used as one of many windowing functions for smoothing values. It is also known as an apodization (which means “removing the foot”, i.e. smoothing discontinuities at the beginning and end of the sampled signal) or tapering function.

Examples

Plot the window and its frequency response:

```python
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt

>>> window = signal.hann(51)
>>> plt.plot(window)
>>> plt.title("Hann window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")

>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the Hann window")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```
scipy.signal.kaiser(M, beta, sym=True)

Return a Kaiser window.

The Kaiser window is a taper formed by using a Bessel function.

**Parameters**

- **M**: int
  Number of points in the output window. If zero or less, an empty array is returned.

- **beta**: float
  Shape parameter, determines trade-off between main-lobe width and side lobe level. As beta gets large, the window narrows.

- **sym**: bool, optional
  When True (default), generates a symmetric window, for use in filter design. When False, generates a periodic window, for use in spectral analysis.

**Returns**

- **w**: ndarray
  The window, with the maximum value normalized to 1 (though the value 1 does not appear if $M$ is even and sym is True).
Notes

The Kaiser window is defined as

\[ w(n) = I_0 \left( \beta \sqrt{1 - \frac{4n^2}{(M-1)^2}} \right) / I_0(\beta) \]

with

\[-\frac{M-1}{2} \leq n \leq \frac{M-1}{2},\]

where \( I_0 \) is the modified zeroth-order Bessel function.

The Kaiser was named for Jim Kaiser, who discovered a simple approximation to the DPSS window based on Bessel functions. The Kaiser window is a very good approximation to the Digital Prolate Spheroidal Sequence, or Slepian window, which is the transform which maximizes the energy in the main lobe of the window relative to total energy.

The Kaiser can approximate other windows by varying the beta parameter. (Some literature uses alpha = beta/pi.) [R282]

<table>
<thead>
<tr>
<th>beta</th>
<th>Window shape</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Rectangular</td>
</tr>
<tr>
<td>5</td>
<td>Similar to a Hamming</td>
</tr>
<tr>
<td>6</td>
<td>Similar to a Hann</td>
</tr>
<tr>
<td>8.6</td>
<td>Similar to a Blackman</td>
</tr>
</tbody>
</table>

A beta value of 14 is probably a good starting point. Note that as beta gets large, the window narrows, and so the number of samples needs to be large enough to sample the increasingly narrow spike, otherwise NaNs will be returned.

Most references to the Kaiser window come from the signal processing literature, where it is used as one of many windowing functions for smoothing values. It is also known as an apodization (which means “removing the foot”, i.e. smoothing discontinuities at the beginning and end of the sampled signal) or tapering function.

[R279], [R280], [R281], [R282]

Examples

Plot the window and its frequency response:

```python
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt

>>> window = signal.kaiser(51, beta=14)
>>> plt.plot(window)
>>> plt.title(r"Kaiser window ($\beta$=14)")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")

>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
```
scipy.signal.nuttall(M, sym=True)

Return a minimum 4-term Blackman-Harris window according to Nuttall.

This variation is called “Nuttall4c” by Heinzel. [R292]

Parameters

- **M**: int
  - Number of points in the output window. If zero or less, an empty array is returned.
- **sym**: bool, optional
  - When True (default), generates a symmetric window, for use in filter design.
  - When False, generates a periodic window, for use in spectral analysis.

Returns

- **w**: ndarray
  - The window, with the maximum value normalized to 1 (though the value 1 does not appear if M is even and sym is True).
**References**

[R291], [R292]

**Examples**

Plot the window and its frequency response:

```python
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt

>>> window = signal.nuttall(51)
>>> plt.plot(window)
>>> plt.title("Nuttall window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")

>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the Nuttall window")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```

![Nuttall window](image)
scipy.signal.parzen(M, sym=True)

Return a Parzen window.

Parameters

- **M**: int
  Number of points in the output window. If zero or less, an empty array is returned.
- **sym**: bool, optional
  When True (default), generates a symmetric window, for use in filter design. When False, generates a periodic window, for use in spectral analysis.

Returns

- **w**: ndarray
  The window, with the maximum value normalized to 1 (though the value 1 does not appear if `M` is even and `sym` is True).

References

[R293]

Examples

Plot the window and its frequency response:

```python
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt

>>> window = signal.parzen(51)
>>> plt.plot(window)
>>> plt.title("Parzen window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")

>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the Parzen window")
```
plt.ylabel("Normalized magnitude [dB]")
plt.xlabel("Normalized frequency [cycles per sample]")

```python
scipy.signal.slepian(M, width, sym=True)
```

Return a digital Slepian (DPSS) window.

Used to maximize the energy concentration in the main lobe. Also called the digital prolate spheroidal sequence (DPSS).

**Parameters**
- **M**: int
  Number of points in the output window. If zero or less, an empty array is returned.
- **width**: float
  Bandwidth
- **sym**: bool, optional
  When True (default), generates a symmetric window, for use in filter design.
  When False, generates a periodic window, for use in spectral analysis.

**Returns**
- **w**: ndarray
The window, with the maximum value always normalized to 1

**References**

[R298], [R299]

**Examples**

Plot the window and its frequency response:

```python
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt

>>> window = signal.slepian(51, width=0.3)
>>> plt.plot(window)
>>> plt.title("Slepian (DPSS) window (BW=0.3)")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")

>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the Slepian window (BW=0.3)"")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]"")
```

![Slepian (DPSS) window (BW=0.3)](image-url)
scipy.signal.triang\((M, \text{sym}=\text{True})\)

Return a triangular window.

**Parameters**
- \(M\): int
  - Number of points in the output window. If zero or less, an empty array is returned.
- \(\text{sym}\): bool, optional
  - When True (default), generates a symmetric window, for use in filter design.
  - When False, generates a periodic window, for use in spectral analysis.

**Returns**
- \(w\): ndarray
  - The window, with the maximum value normalized to 1 (though the value 1 does not appear if \(M\) is even and \(\text{sym}\) is True).

**See also:**
- bartlett  
  A triangular window that touches zero

**Examples**

Plot the window and its frequency response:

```python
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt
```

```python
>>> window = signal.triang(51)
>>> plt.plot(window)
>>> plt.title("Triangular window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")

>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the triangular window")
```
```python
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```

![Triangular window graph](image1)

![Frequency response of the triangular window graph](image2)

```python
scipy.signal.tukey(M, alpha=0.5, sym=True)
```

Return a Tukey window, also known as a tapered cosine window.

**Parameters**

- **M**: int
  Number of points in the output window. If zero or less, an empty array is returned.

- **alpha**: float, optional
  Shape parameter of the Tukey window, representing the fraction of the window inside the cosine tapered region. If zero, the Tukey window is equivalent to a rectangular window. If one, the Tukey window is equivalent to a Hann window.

- **sym**: bool, optional
  When True (default), generates a symmetric window, for use in filter design. When False, generates a periodic window, for use in spectral analysis.
Returns

\( w : \text{ndarray} \)

The window, with the maximum value normalized to 1 (though the value 1 does not appear if \( M \) is even and \( \text{sym} \) is True).

References

[R303], [R304]

Examples

Plot the window and its frequency response:

```python
>>> from scipy import signal
>>> from scipy.fftpack import fft, fftshift
>>> import matplotlib.pyplot as plt

>>> window = signal.tukey(51)
>>> plt.plot(window)
>>> plt.title("Tukey window")
>>> plt.ylabel("Amplitude")
>>> plt.xlabel("Sample")
>>> plt.ylim([0, 1.1])

>>> plt.figure()
>>> A = fft(window, 2048) / (len(window)/2.0)
>>> freq = np.linspace(-0.5, 0.5, len(A))
>>> response = 20 * np.log10(np.abs(fftshift(A / abs(A).max())))
>>> plt.plot(freq, response)
>>> plt.axis([-0.5, 0.5, -120, 0])
>>> plt.title("Frequency response of the Tukey window")
>>> plt.ylabel("Normalized magnitude [dB]")
>>> plt.xlabel("Normalized frequency [cycles per sample]")
```

Tukey window

![Tukey window plot](image_url)
5.20.11 Wavelets

\texttt{cascade(hk[, J])}

Return \((x, \phi, \psi)\) at dyadic points \(K/2^J\) from filter coefficients.

\texttt{daub(p)}

The coefficients for the FIR low-pass filter producing Daubechies wavelets.

\texttt{morlet(M[, w, s, complete])}

Complex Morlet wavelet.

\texttt{qmf(hk)}

Return high-pass qmf filter from low-pass

\texttt{ricker(points, a)}

Return a Ricker wavelet, also known as the “Mexican hat wavelet”.

\texttt{cwt(data, wavelet, widths)}

Continuous wavelet transform.

\texttt{scipy.signal.cascade(hk,J=7)}

Return \((x, \phi, \psi)\) at dyadic points \(K/2^J\) from filter coefficients.

\texttt{Parameters}

\begin{itemize}
  \item \texttt{hk} : array_like
    Coefficients of low-pass filter.
  \item \texttt{J} : int, optional
    Values will be computed at grid points \(K/2^J\). Default is 7.
\end{itemize}

\texttt{Returns}

\begin{itemize}
  \item \texttt{x} : ndarray
    The dyadic points \(K/2^J\) for \(K=0\ldots N\times(2^J)-1\) where
    \(\text{len}(hk) = \text{len}(gk) = N+1\).
  \item \texttt{phi} : ndarray
    The scaling function \(\phi(x)\) at \(x\): \(\phi(x) = \sum(hk \ast \phi(2x-k))\), where \(k\) is from 0 to \(N\).
  \item \texttt{psi} : ndarray, optional
    The wavelet function \(\psi(x)\) at \(x\): \(\psi(x) = \sum(gk \ast \phi(2x-k))\), where \(k\) is from 0 to \(N\). \(\psi\) is only returned if \(gk\) is not None.
\end{itemize}

\texttt{Notes}

The algorithm uses the vector cascade algorithm described by Strang and Nguyen in “Wavelets and Filter Banks”. It builds a dictionary of values and slices for quick reuse. Then inserts vectors into final vector at
the end.

```
scipy.signal.daub(p)
```

The coefficients for the FIR low-pass filter producing Daubechies wavelets.

\( p \geq 1 \) gives the order of the zero at \( f=1/2 \). There are \( 2p \) filter coefficients.

**Parameters**

- **p**: int

**Returns**

- **daub**: ndarray
  
  The coefficients for the FIR low-pass filter producing Daubechies wavelets.

```
scipy.signal.morlet(M, w=5.0, s=1.0, complete=True)
```

Complex Morlet wavelet.

**Parameters**

- **M**: int
  
  Length of the wavelet.

- **w**: float, optional
  
  Omega0. Default is 5

- **s**: float, optional
  
  Scaling factor, windowed from \(-s*2*pi\) to \(+s*2*pi\). Default is 1.

- **complete**: bool, optional
  
  Whether to use the complete or the standard version.

**Returns**

- **morlet**: (M,) ndarray

**See also:**

```
scipy.signal.gausspulse
```

**Notes**

The standard version:

\[
\pi^{-0.25} \times \exp(j \omega x) \times \exp(-0.5 \times (x^2))
\]

This commonly used wavelet is often referred to simply as the Morlet wavelet. Note that this simplified version can cause admissibility problems at low values of \( w \).

The complete version:

\[
\pi^{-0.25} \times (\exp(j \omega x) - \exp(-0.5 \times (w^2))) \times \exp(-0.5 \times (x^2))
\]

This version has a correction term to improve admissibility. For \( w \) greater than 5, the correction term is negligible.

Note that the energy of the return wavelet is not normalised according to \( s \).

The fundamental frequency of this wavelet in Hz is given by \( f = 2 * s * w * r / M \) where \( r \) is the sampling rate.

Note: This function was created before `cwt` and is not compatible with it.

```
scipy.signal.qmf(hk)
```

Return high-pass qmf filter from low-pass

**Parameters**

- **hk**: array_like
  
  Coefficients of high-pass filter.

```
scipy.signal.ricker(points, a)
```

Return a Ricker wavelet, also known as the “Mexican hat wavelet”.

It models the function:

\[
A \times (1 - x^2/a^2) \times \exp(-x^2/2 a^2),
\]
where \( A = \frac{2}{\sqrt{3a}}\pi^{1/4} \).

**Parameters**

- **points** : int
  
  Number of points in vector. Will be centered around 0.

- **a** : scalar
  
  Width parameter of the wavelet.

**Returns**

- **vector** : (N,) ndarray
  
  Array of length points in shape of ricker curve.

**Examples**

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

>>> points = 100
>>> a = 4.0
>>> vec2 = signal.ricker(points, a)
>>> print(len(vec2))
100
>>> plt.plot(vec2)
```

![Graph of ricker wavelet](image.png)

-scipy.signal.cwt(data, wavelet, widths)-

Continuous wavelet transform.

Perform a continuous wavelet transform on data, using the wavelet function. A CWT performs a convolution with data using the wavelet function, which is characterized by a width parameter and length parameter.

**Parameters**

- **data** : (N,) ndarray
  
  data on which to perform the transform.

- **wavelet** : function
  
  Wavelet function, which should take 2 arguments. The first argument is the number of points that the returned vector will have (len(wavelet(length,width)) == length). The second is a width parameter, defining the size of the wavelet (e.g. standard deviation of a gaussian). See ricker, which satisfies these requirements.

- **widths** : (M,) sequence
  
  Widths to use for transform.

**Returns**

- **cwt** : (M, N) ndarray
  
  Continuous wavelet transform result.
Notes

\[
\text{length} = \min(10 \times \text{width}[\text{ii}], \text{len(data)})
\]
\[
cwt[\text{ii},:] = \text{signal.convolve(data, wavelet(length, width[\text{ii})], mode='same')}
\]

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> t = np.linspace(-1, 1, 200, endpoint=False)
>>> sig = np.cos(2 * np.pi * 7 * t) + signal.gausspulse(t - 0.4, fc=2)
>>> widths = np.arange(1, 31)
>>> cwtmatr = signal.cwt(sig, signal.ricker, widths)
>>> plt.imshow(cwtmatr, extent=[-1, 1, 31, 1], cmap='PRGn', aspect='auto', ...
...    vmax=abs(cwtmatr).max(), vmin=-abs(cwtmatr).max())
>>> plt.show()
```

### 5.20.12 Peak finding

- `find_peaks_cwt(vector, widths[, wavelet, ...])`: Attempt to find the peaks in a 1-D array.
- `argrelmin(data[, axis, order, mode])`: Calculate the relative minima of `data`.
- `argrelmax(data[, axis, order, mode])`: Calculate the relative maxima of `data`.
- `argrelextrema(data, comparator[, axis, ...])`: Calculate the relative extrema of `data`.

```python
scipy.signal.find_peaks_cwt (vector, widths, wavelet=None, max_distances=None,
    gap_thresh=None, min_length=None, min_snr=1, noise_perc=10)
```

Attempt to find the peaks in a 1-D array.

The general approach is to smooth `vector` by convolving it with `wavelet(width)` for each width in `widths`. Relative maxima which appear at enough length scales, and with sufficiently high SNR, are accepted.

**Parameters**

- `vector` : ndarray

5.20. Signal processing (scipy.signal) 1261
1-D array in which to find the peaks.

**widths** : sequence

1-D array of widths to use for calculating the CWT matrix. In general, this range should cover the expected width of peaks of interest.

**wavelet** : callable, optional

Should take two parameters and return a 1-D array to convolve with vector. The first parameter determines the number of points of the returned wavelet array, the second parameter is the scale (width) of the wavelet. Should be normalized and symmetric. Default is the ricker wavelet.

**max_distances** : ndarray, optional

At each row, a ridge line is only connected if the relative max at row[n] is within max_distances[n] from the relative max at row[n+1]. Default value is widths/4.

**gap_thresh** : float, optional

If a relative maximum is not found within max_distances, there will be a gap. A ridge line is discontinued if there are more than gap_thresh points without connecting a new relative maximum. Default is the first value of the widths array i.e. widths[0].

**min_length** : int, optional

Minimum length a ridge line needs to be acceptable. Default is \( \text{cwt} \cdot \text{shape}[0] / 4 \), i.e. 1/4-th the number of widths.

**min_snr** : float, optional

Minimum SNR ratio. Default 1. The signal is the value of the cwt matrix at the shortest length scale (\( \text{cwt}[0, \text{loc}] \)), the noise is the noise_perc’th percentile of datapoints contained within a window of ‘window_size’ around \( \text{cwt}[0, \text{loc}] \).

**noise_perc** : float, optional

When calculating the noise floor, percentile of data points examined below which to consider noise. Calculated using stats.scoreatpercentile. Default is 10.

**Returns**

**peaks_indices** : ndarray

Indices of the locations in the vector where peaks were found. The list is sorted.

See also:

cwt

Notes

This approach was designed for finding sharp peaks among noisy data, however with proper parameter selection it should function well for different peak shapes.

*The algorithm is as follows:*

1. Perform a continuous wavelet transform on vector, for the supplied widths. This is a convolution of vector with wavelet(width) for each width in widths. See cwt
2. Identify “ridge lines” in the cwt matrix. These are relative maxima at each row, connected across adjacent rows. See identify_ridge_lines
3. Filter the ridge_lines using filter_ridge_lines.

New in version 0.11.0.

References

[R253]
Examples

```python
>>> from scipy import signal
>>> xs = np.arange(0, np.pi, 0.05)
>>> data = np.sin(xs)
>>> peakind = signal.find_peaks_cwt(data, np.arange(1,10))
>>> peakind, xs[peakind], data[peakind]
([32], array([ 1.6]), array([ 0.9995736]))
```

`scipy.signal.argrelmin(data, axis=0, order=1, mode='clip')`
Calculate the relative minima of `data`.

**Parameters**
- **data**: ndarray
  - Array in which to find the relative minima.
- **axis**: int, optional
  - Axis over which to select from `data`. Default is 0.
- **order**: int, optional
  - How many points on each side to use for the comparison to consider `comparator(n, n+x)` to be True.
- **mode**: str, optional
  - How the edges of the vector are treated. Available options are ‘wrap’ (wrap around) or ‘clip’ (treat overflow as the same as the last (or first) element).

**Returns**
- **extrema**: tuple of ndarrays
  - Indices of the minima in arrays of integers. `extrema[k]` is the array of indices of axis `k` of `data`. Note that the return value is a tuple even when `data` is one-dimensional.

See also:
- `argrelextrema`, `argrelmax`

Notes
This function uses `argrelextrema` with `np.less` as comparator.

New in version 0.11.0.

Examples

```python
>>> from scipy.signal import argrelmin
>>> x = np.array([2, 1, 2, 3, 2, 0, 1, 0])
>>> argrelmin(x)
(array([1, 5]),)
```

`scipy.signal.argrelmax(data, axis=0, order=1, mode='clip')`
Calculate the relative maxima of `data`.

**Parameters**
- **data**: ndarray
  - Array in which to find the relative maxima.
- **axis**: int, optional
  - Axis over which to select from `data`. Default is 0.
- **order**: int, optional

5.20. Signal processing (`scipy.signal`) 1263
Returns

extrema : tuple of ndarrays

Indices of the maxima in arrays of integers. extrema[k] is the array of indices of axis k of data. Note that the return value is a tuple even when data is one-dimensional.

See also:

argrelextrema, argrelmin

Notes

This function uses argrelextrema with np.greater as comparator.

New in version 0.11.0.

Examples

```python
>>> from scipy.signal import argrelmax
>>> x = np.array([2, 1, 2, 3, 2, 0, 1, 0])
>>> argrelmax(x)
(array([3, 6]),)
>>> y = np.array([[1, 2, 1, 2],
           [2, 2, 0, 0],
           [5, 3, 4, 4]])
>>> argrelmax(y, axis=1)
(array([0]), array([1]))
```

scipy.signal.argrelextrema(data, comparator, axis=0, order=1, mode='clip')

Calculate the relative extrema of data.

Parameters

data : ndarray

Array in which to find the relative extrema.

comparator : callable

Function to use to compare two data points. Should take two arrays as arguments.

axis : int, optional

Axis over which to select from data. Default is 0.

order : int, optional

How many points on each side to use for the comparison to consider comparator(n, n+x) to be True.

mode : str, optional

How the edges of the vector are treated. ‘wrap’ (wrap around) or ‘clip’ (treat overflow as the same as the last (or first) element). Default is ‘clip’. See numpy.take.

Returns

extrema : tuple of ndarrays

Indices of the maxima in arrays of integers. extrema[k] is the array of indices of axis k of data. Note that the return value is a tuple even when data is one-dimensional.

See also:

argrelmin, argrelmax
**Notes**

New in version 0.11.0.

**Examples**

```python
>>> from scipy.signal import argrelextrema
>>> x = np.array([2, 1, 2, 3, 2, 0, 1, 0])
>>> argrelextrema(x, np.greater)
(array([3, 6]),)
>>> y = np.array([[1, 2, 1, 2],
    ... [2, 2, 0, 0],
    ... [5, 3, 4, 4]])
>>> argrelextrema(y, np.less, axis=1)
(array([0, 2]), array([2, 1]))
```

```python
scipy.signal.periodogram(x, fs=1.0, window='boxcar', nfft=None, detrend='constant', return_onesided=True, scaling='density', axis=-1)
```

Estimate power spectral density using a periodogram.

**Parameters**

- **x**: array_like
  - Time series of measurement values
- **fs**: float, optional
  - Sampling frequency of the $x$ time series. Defaults to 1.0.
- **window**: str or tuple or array_like, optional
  - Desired window to use. If `window` is a string or tuple, it is passed to `get_window` to generate the window values, which are DFT-even by default. See `get_window` for a list of windows and required parameters. If `window` is array_like it will be used directly as the window and its length must be nperseg. Defaults to ‘boxcar’.
- **nfft**: int, optional
  - Length of the FFT used. If `None` the length of $x$ will be used.
- **detrend**: str or function or `False`, optional

---

5.20. Signal processing (`scipy.signal`) 1265
Specifies how to detrend each segment. If `detrend` is a string, it is passed as the type argument to the `detrend` function. If it is a function, it takes a segment and returns a detrended segment. If `detrend` is `False`, no detrending is done. Defaults to 'constant'.

`return_onesided` : bool, optional
If `True`, return a one-sided spectrum for real data. If `False` return a two-sided spectrum. Note that for complex data, a two-sided spectrum is always returned.

`scaling` : {‘density’, ‘spectrum’}, optional
Selects between computing the power spectral density (‘density’) where \( P_{xx} \) has units of \( V^2/\text{Hz} \) and computing the power spectrum (‘spectrum’) where \( P_{xx} \) has units of \( V^2 \), if \( x \) is measured in \( V \) and \( fs \) is measured in Hz. Defaults to ‘density’

`axis` : int, optional
Axis along which the periodogram is computed; the default is over the last axis (i.e. \( \text{axis}=-1 \)).

Returns

\( f \) : ndarray
Array of sample frequencies.

\( P_{xx} \) : ndarray
Power spectral density or power spectrum of \( x \).

`welch` Estimate power spectral density using Welch’s method

`lombscargle` Lomb-Scargle periodogram for unevenly sampled data

Notes

New in version 0.12.0.

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

Generate a test signal, a 2 Vrms sine wave at 1234 Hz, corrupted by 0.001 V**2/Hz of white noise sampled at 10 kHz.

```python
>>> fs = 10e3
>>> N = 1e5
>>> amp = 2*np.sqrt(2)
>>> freq = 1234.0
>>> noise_power = 0.001 * fs / 2
>>> time = np.arange(N) / fs
>>> x = amp*np.sin(2*np.pi*freq*time)
>>> x += np.random.normal(scale=np.sqrt(noise_power), size=time.shape)
``` generate

Compute and plot the power spectral density.

```python
>>> f, Pxx_den = signal.periodogram(x, fs)
>>> plt.semilogy(f, Pxx_den)
>>> plt.ylim([1e-7, 1e2])
>>> plt.xlabel('frequency [Hz]')
>>> plt.ylabel('PSD [V**2/Hz]')
>>> plt.show()
```
If we average the last half of the spectral density, to exclude the peak, we can recover the noise power on the signal.

```python
>>> np.mean(Pxx_den[25000:])
0.00099728892368242854
```

Now compute and plot the power spectrum.

```python
>>> f, Pxx_spec = signal.periodogram(x, fs, 'flattop', scaling='spectrum')
>>> plt.figure()
>>> plt.semilogy(f, np.sqrt(Pxx_spec))
>>> plt.ylim([1e-4, 1e1])
>>> plt.xlabel('frequency [Hz]')
>>> plt.ylabel('Linear spectrum [V RMS]')
>>> plt.show()
```

The peak height in the power spectrum is an estimate of the RMS amplitude.
scipy.signal.welch(x, fs=1.0, window='hann', nperseg=None, noverlap=None, nfft=None, detrend='constant', return_onesided=True, scaling='density', axis=-1)

Estimate power spectral density using Welch’s method.

Welch’s method [R306] computes an estimate of the power spectral density by dividing the data into overlapping segments, computing a modified periodogram for each segment and averaging the periodograms.

Parameters

- **x**: array_like
  Time series of measurement values
- **fs**: float, optional
  Sampling frequency of the x time series. Defaults to 1.0.
- **window**: str or tuple or array_like, optional
  Desired window to use. If window is a string or tuple, it is passed to get_window to generate the window values, which are DFT-even by default. See get_window for a list of windows and required parameters. If window is array_like it will be used directly as the window and its length must be nperseg. Defaults to a Hann window.
- **nperseg**: int, optional
  Length of each segment. Defaults to None, but if window is str or tuple, is set to 256, and if window is array_like, is set to the length of the window.
- **noverlap**: int, optional
  Number of points to overlap between segments. If None, noverlap = nperseg // 2. Defaults to None.
- **nfft**: int, optional
  Length of the FFT used, if a zero padded FFT is desired. If None, the FFT length is nperseg. Defaults to None.
- **detrend**: str or function or False, optional
  Specifies how to detrend each segment. If detrend is a string, it is passed as the type argument to the detrend function. If it is a function, it takes a segment and returns a detrended segment. If detrend is False, no detrending is done. Defaults to ‘constant’.
- **return_onesided**: bool, optional
  If True, return a one-sided spectrum for real data. If False return a two-sided spectrum. Note that for complex data, a two-sided spectrum is always returned.
- **scaling**: {‘density’, ‘spectrum’}, optional
  Selects between computing the power spectral density (‘density’) where $P_{xx}$ has units of $V^2/\text{Hz}$ and computing the power spectrum (‘spectrum’) where $P_{xx}$ has units of $V^2$, if $x$ is measured in $V$ and $fs$ is measured in Hz. Defaults to ‘density’
- **axis**: int, optional
  Axis along which the periodogram is computed; the default is over the last axis (i.e. axis=-1).

Returns

- **f**: ndarray
  Array of sample frequencies.
- **Pxx**: ndarray
  Power spectral density or power spectrum of x.

See also:

- periodogram
  Simple, optionally modified periodogram
**lombscargle**

Lomb-Scargle periodogram for unevenly sampled data

**Notes**

An appropriate amount of overlap will depend on the choice of window and on your requirements. For the default Hann window an overlap of 50% is a reasonable trade off between accurately estimating the signal power, while not over counting any of the data. Narrower windows may require a larger overlap.

If `noverlap` is 0, this method is equivalent to Bartlett’s method [R307].

New in version 0.12.0.

[R306], [R307]

**Examples**

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
>>> np.random.seed(1234)

Generate a test signal, a 2 Vrms sine wave at 1234 Hz, corrupted by 0.001 V**2/Hz of white noise sampled at 10 kHz.

```python
def noise_power = 0.001 * fs / 2
time = np.arange(N) / fs
x = amp * np.sin(2 * np.pi * freq * time)
x += np.random.normal(scale=np.sqrt(noise_power), size=time.shape)
```  
Compute and plot the power spectral density.

```python
>>> f, Pxx_den = signal.welch(x, fs, nperseg=1024)
>>> plt.semilogy(f, Pxx_den)
>>> plt.ylim([0.5e-3, 1])
>>> plt.xlabel('frequency [Hz]')
>>> plt.ylabel('PSD [V**2/Hz]')
>>> plt.show()
```
If we average the last half of the spectral density, to exclude the peak, we can recover the noise power on the signal.

```python
>>> np.mean(Pxx_den[256:])
0.0009924865443739191
```

Now compute and plot the power spectrum.

```python
>>> f, Pxx_spec = signal.welch(x, fs, 'flattop', 1024, scaling='spectrum')
>>> plt.figure()
>>> plt.semilogy(f, np.sqrt(Pxx_spec))
>>> plt.xlabel('frequency [Hz]')
>>> plt.ylabel('Linear spectrum [V RMS]')
>>> plt.show()
```

The peak height in the power spectrum is an estimate of the RMS amplitude.
scipy.signal.csd(x, y, fs=1.0, window='hann', nperseg=None, noverlap=None, nfft=None, detrend='constant', return_onesided=True, scaling='density', axis=-1)

Estimate the cross power spectral density, \( P_{xy} \), using Welch’s method.

**Parameters**

- **x**: array_like
  - Time series of measurement values

- **y**: array_like
  - Time series of measurement values

- **fs**: float, optional
  - Sampling frequency of the \( x \) and \( y \) time series. Defaults to 1.0.

- **window**: str or tuple or array_like, optional
  - Desired window to use. If \( window \) is a string or tuple, it is passed to `get_window` to generate the window values, which are DFT-even by default. See `get_window` for a list of windows and required parameters. If \( window \) is array_like it will be used directly as the window and its length must be nperseg. Defaults to a Hann window.

- **nperseg**: int, optional
  - Length of each segment. Defaults to None, but if window is str or tuple, is set to 256, and if window is array_like, is set to the length of the window.

- **noverlap**: int, optional
  - Number of points to overlap between segments. If None, noverlap = nperseg // 2. Defaults to None.

- **nfft**: int, optional
  - Length of the FFT used, if a zero padded FFT is desired. If None, the FFT length is nperseg. Defaults to None.

- **detrend**: str or function or False, optional
  - Specifies how to detrend each segment. If \( detrend \) is a string, it is passed as the type argument to the `detrend` function. If it is a function, it takes a segment and returns a detrended segment. If \( detrend \) is False, no detrending is done. Defaults to ‘constant’.

- **return_onesided**: bool, optional
  - If True, return a one-sided spectrum for real data. If False return a two-sided spectrum. Note that for complex data, a two-sided spectrum is always returned.

- **scaling**: { ‘density’, ‘spectrum’ }, optional
  - Selects between computing the cross spectral density (‘density’) where \( P_{xy} \) has units of \( V^2/Hz \) and computing the cross spectrum (‘spectrum’) where \( P_{xy} \) has units of \( V^2 \), if \( x \) and \( y \) are measured in V and \( fs \) is measured in Hz. Defaults to ‘density’

- **axis**: int, optional
  - Axis along which the CSD is computed for both inputs; the default is over the last axis (i.e. axis=-1).

**Returns**

- **f**: ndarray
  - Array of sample frequencies.

- **Pxy**: ndarray
  - Cross spectral density or cross power spectrum of \( x, y \).

See also:

- **periodogram**
  - Simple, optionally modified periodogram

- **lombscargle**
  - Lomb-Scargle periodogram for unevenly sampled data
**welch**  
Power spectral density by Welch’s method. [Equivalent to csd(x,x)]

**coherence**  
Magnitude squared coherence by Welch’s method.

**Notes**

By convention, \( P_{xy} \) is computed with the conjugate FFT of \( X \) multiplied by the FFT of \( Y \).

If the input series differ in length, the shorter series will be zero-padded to match.

An appropriate amount of overlap will depend on the choice of window and on your requirements. For the default Hann window an overlap of 50% is a reasonable trade off between accurately estimating the signal power, while not over counting any of the data. Narrower windows may require a larger overlap.

New in version 0.16.0.

**Examples**

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

Generate two test signals with some common features.

```python
>>> fs = 10e3
>>> N = 1e5
>>> amp = 20
>>> freq = 1234.0
>>> noise_power = 0.001 * fs / 2
>>> time = np.arange(N) / fs
>>> b, a = signal.butter(2, 0.25, 'low')
>>> x = np.random.normal(scale=np.sqrt(noise_power), size=time.shape)
>>> y = signal.lfilter(b, a, x)
>>> x += amp*np.sin(2*np.pi*freq*time)
>>> y += np.random.normal(scale=0.1*np.sqrt(noise_power), size=time.shape)

Compute and plot the magnitude of the cross spectral density.

```python
>>> f, Pxy = signal.csd(x, y, fs, nperseg=1024)
>>> plt.semilogy(f, np.abs(Pxy))
>>> plt.xlabel('frequency [Hz]')
>>> plt.ylabel('CSD [V**2/Hz]')
>>> plt.show()
```

scipy.signal.coherence(x, y, fs=1.0, window='hann', nperseg=None, noverlap=None, nfft=None, detrend='constant', axis=-1)

Estimate the magnitude squared coherence estimate, Cxy, of discrete-time signals X and Y using Welch’s method.

\[ C_{xy} = \frac{|P_{xy}|^2}{P_{xx}P_{yy}} \]

where \( P_{xx} \) and \( P_{yy} \) are power spectral density estimates of X and Y, and \( P_{xy} \) is the cross spectral density estimate of X and Y.

**Parameters**

- **x**: array_like
  Time series of measurement values

- **y**: array_like
  Time series of measurement values

- **fs**: float, optional
  Sampling frequency of the x and y time series. Defaults to 1.0.

- **window**: str or tuple or array_like, optional
  Desired window to use. If window is a string or tuple, it is passed to `get_window` to generate the window values, which are DFT-even by default. See `get_window` for a list of windows and required parameters. If window is array_like it will be used directly as the window and its length must be nperseg. Defaults to a Hann window.

- **nperseg**: int, optional
  Length of each segment. Defaults to None, but if window is str or tuple, is set to 256, and if window is array_like, is set to the length of the window.

- **noverlap**: int, optional
  Number of points to overlap between segments. If None, noverlap = nperseg // 2. Defaults to None.

- **nfft**: int, optional
  Length of the FFT used, if a zero padded FFT is desired. If None, the FFT length is nperseg. Defaults to None.

- **detrend**: str or function or False, optional
  Specifies how to detrend each segment. If detrend is a string, it is passed as the type argument to the detrend function. If it is a function, it takes a segment and returns a detrended segment. If detrend is False, no detrending is done. Defaults to ‘constant’.

- **axis**: int, optional
Axis along which the coherence is computed for both inputs; the default is over the last axis (i.e. `axis=-1`).

**Returns**

- `f` : ndarray
  Array of sample frequencies.
- `Cxy` : ndarray
  Magnitude squared coherence of x and y.

Generate two test signals with some common features.

```python
>>> fs = 10e3
>>> N = 1e5
>>> amp = 20
>>> freq = 1234.0
>>> noise_power = 0.001 * fs / 2
>>> time = np.arange(N) / fs
>>> b, a = signal.butter(2, 0.25, 'low')
>>> x = np.random.normal(scale=np.sqrt(noise_power), size=time.shape)
>>> y = signal.lfilter(b, a, x)
>>> x += amp*np.sin(2*np.pi*freq*time)
>>> y += np.random.normal(scale=0.1*np.sqrt(noise_power), size=time.shape)

Compute and plot the coherence.

```python
>>> f, Cxy = signal.coherence(x, y, fs, nperseg=1024)
>>> plt.semilogy(f, Cxy)
>>> plt.xlabel('frequency [Hz]')
>>> plt.ylabel('Coherence')
>>> plt.show()
```
scipy.signal.spectrogram(x, fs=1.0, window=('tukey', 0.25), nperseg=None, noverlap=None, nfft=None, detrend='constant', return_onesided=True, scaling='density', axis=-1, mode='psd')

Compute a spectrogram with consecutive Fourier transforms.

Spectrograms can be used as a way of visualizing the change of a nonstationary signal’s frequency content over time.

**Parameters**

- **x**: array_like
  - Time series of measurement values
- **fs**: float, optional
  - Sampling frequency of the x time series. Defaults to 1.0.
- **window**: str or tuple or array_like, optional
  - Desired window to use. If window is a string or tuple, it is passed to get_window to generate the window values, which are DFT-even by default. See get_window for a list of windows and required parameters. If window is array_like it will be used directly as the window and its length must be nperseg. Defaults to a Tukey window with shape parameter of 0.25.
- **nperseg**: int, optional
  - Length of each segment. Defaults to None, but if window is str or tuple, is set to 256, and if window is array_like, is set to the length of the window.
- **noverlap**: int, optional
  - Number of points to overlap between segments. If None, noverlap = nperseg // 8. Defaults to None.
- **nfft**: int, optional
  - Length of the FFT used, if a zero padded FFT is desired. If None, the FFT length is nperseg. Defaults to None.
- **detrend**: str or function or False, optional
  - Specifies how to detrend each segment. If detrend is a string, it is passed as the type argument to the detrend function. If it is a function, it takes a segment and returns a detrended segment. If detrend is False, no detrending is done. Defaults to ‘constant’.
- **return_onesided**: bool, optional
  - If True, return a one-sided spectrum for real data. If False return a two-sided spectrum. Note that for complex data, a two-sided spectrum is always returned.
scaling : \{ 'density', 'spectrum' \}, optional
Selects between computing the power spectral density ('density') where $S_{xx}$ has units of V**2/Hz and computing the power spectrum ('spectrum') where $S_{xx}$ has units of V**2, if $x$ is measured in V and $fs$ is measured in Hz. Defaults to 'density'.

axis : int, optional
Axis along which the spectrogram is computed; the default is over the last axis (i.e. axis=-1).

mode : str, optional
Defines what kind of return values are expected. Options are ['psd', 'complex', 'magnitude', 'angle', 'phase']. 'complex' is equivalent to the output of stft with no padding or boundary extension. 'magnitude' returns the absolute magnitude of the STFT. 'angle' and 'phase' return the complex angle of the STFT, with and without unwrapping, respectively.

Returns
f : ndarray
Array of sample frequencies.
t : ndarray
Array of segment times.
$S_{xx}$ : ndarray
Spectrogram of $x$. By default, the last axis of $S_{xx}$ corresponds to the segment times.

See also:
periodogram
Simple, optionally modified periodogram
lombscargle
Lomb-Scargle periodogram for unevenly sampled data
welch
Power spectral density by Welch's method.
csd
Cross spectral density by Welch's method.

Notes
An appropriate amount of overlap will depend on the choice of window and on your requirements. In contrast to welch’s method, where the entire data stream is averaged over, one may wish to use a smaller overlap (or perhaps none at all) when computing a spectrogram, to maintain some statistical independence between individual segments. It is for this reason that the default window is a Tukey window with 1/8th of a window’s length overlap at each end.

New in version 0.16.0.

References
[R300]

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt
```

Generate a test signal, a 2 Vrms sine wave whose frequency is slowly modulated around 3kHz, corrupted by white noise of exponentially decreasing magnitude sampled at 10 kHz.

```python
>>> fs = 10e3
>>> N = 1e5
>>> amp = 2 * np.sqrt(2)
>>> noise_power = 0.01 * fs / 2
>>> time = np.arange(N) / float(fs)
```
Compute and plot the spectrogram.

```python
>>> f, t, Sxx = signal.spectrogram(x, fs)
>>> plt.pcolormesh(t, f, Sxx)
>>> plt.ylabel('Frequency [Hz]')
>>> plt.xlabel('Time [sec]')
>>> plt.show()
```

Pyplot output:

![Spectrogram Plot](image)

**scipy.signal.lombscargle** *(x, y, freqs)*

Computes the Lomb-Scargle periodogram.

The Lomb-Scargle periodogram was developed by Lomb \[R283\] and further extended by Scargle \[R284\] to find, and test the significance of weak periodic signals with uneven temporal sampling.

When `normalize` is False (default) the computed periodogram is unnormalized, it takes the value \((A^2) \times N/4\) for a harmonic signal with amplitude \(A\) for sufficiently large \(N\).

When `normalize` is True the computed periodogram is is normalized by the residuals of the data around a constant reference model (at zero).

Input arrays should be one-dimensional and will be cast to float64.

**Parameters**

- **x** : array_like
  - Sample times.
- **y** : array_like
  - Measurement values.
- **freqs** : array_like
  - Angular frequencies for output periodogram.
- **precenter** : bool, optional
  - Pre-center amplitudes by subtracting the mean.
- **normalize** : bool, optional
  - Compute normalized periodogram.

**Returns**

- **pgram** : array_like
  - Compute normalized periodogram.
Lomb-Scargle periodogram.

Raises ValueError
If the input arrays x and y do not have the same shape.

Notes
This subroutine calculates the periodogram using a slightly modified algorithm due to Townsend [R285] which allows the periodogram to be calculated using only a single pass through the input arrays for each frequency.

The algorithm running time scales roughly as O(x * freqs) or O(N^2) for a large number of samples and frequencies.

References
[R283], [R284], [R285]

Examples

```python
>>> import scipy.signal
>>> import matplotlib.pyplot as plt

First define some input parameters for the signal:

```python
>>> A = 2.
>>> w = 1.
>>> phi = 0.5 * np.pi
>>> nin = 1000
>>> nout = 100000
>>> frac_points = 0.9 # Fraction of points to select
```

Randomly select a fraction of an array with timesteps:

```python
>>> r = np.random.rand(nin)
>>> x = np.linspace(0.01, 10*np.pi, nin)
>>> x = x[r >= frac_points]
```

Plot a sine wave for the selected times:

```python
>>> y = A * np.sin(w*x+phi)
```

Define the array of frequencies for which to compute the periodogram:

```python
>>> f = np.linspace(0.01, 10, nout)
```

Calculate Lomb-Scargle periodogram:

```python
>>> import scipy.signal as signal
>>> pgram = signal.lombscargle(x, y, f, normalize=True)
```

Now make a plot of the input data:

```python
>>> plt.subplot(2, 1, 1)
>>> plt.plot(x, y, 'b+')
```

Then plot the normalized periodogram:

```python
>>> plt.subplot(2, 1, 2)
>>> plt.plot(f, pgram)
>>> plt.show()
```
scipy.signal.vectorstrength(events, period)

Determine the vector strength of the events corresponding to the given period.

The vector strength is a measure of phase synchrony, how well the timing of the events is synchronized to a single period of a periodic signal.

If multiple periods are used, calculate the vector strength of each. This is called the “resonating vector strength”.

Parameters

- **events**: 1D array_like
  An array of time points containing the timing of the events.

- **period**: float or array_like
  The period of the signal that the events should synchronize to. The period is in the same units as `events`. It can also be an array of periods, in which case the outputs are arrays of the same length.

Returns

- **strength**: float or 1D array
  The strength of the synchronization. 1.0 is perfect synchronization and 0.0 is no synchronization. If `period` is an array, this is also an array with each element containing the vector strength at the corresponding period.

- **phase**: float or array
  The phase that the events are most strongly synchronized to in radians. If `period` is an array, this is also an array with each element containing the phase for the corresponding period.

References

scipy.signal.stft(x, fs=1.0, window='hann', nperseg=256, noverlap=None, nfft=None, detrend=False, return_onesided=True, boundary='zeros', padded=True, axis=-1)

Compute the Short Time Fourier Transform (STFT).
STFTs can be used as a way of quantifying the change of a nonstationary signal’s frequency and phase content over time.

**Parameters**

- **x**: array_like
  Time series of measurement values
- **fs**: float, optional
  Sampling frequency of the x time series. Defaults to 1.0.
- **window**: str or tuple or array_like, optional
  Desired window to use. If window is a string or tuple, it is passed to `get_window` to generate the window values, which are DFT-even by default. See `get_window` for a list of windows and required parameters. If window is array_like it will be used directly as the window and its length must be nperseg. Defaults to a Hann window.
- **nperseg**: int, optional
  Length of each segment. Defaults to 256.
- **noverlap**: int, optional
  Number of points to overlap between segments. If None, nooverlap = nperseg // 2. Defaults to None. When specified, the COLA constraint must be met (see Notes below).
- **nfft**: int, optional
  Length of the FFT used, if a zero padded FFT is desired. If None, the FFT length is nperseg. Defaults to None.
- **detrend**: str or function or False, optional
  Specifies how to detrend each segment. If detrend is a string, it is passed as the type argument to the detrend function. If it is a function, it takes a segment and returns a detrended segment. If detrend is False, no detrending is done. Defaults to False.
- **return_onesided**: bool, optional
  If True, return a one-sided spectrum for real data. If False return a two-sided spectrum. Note that for complex data, a two-sided spectrum is always returned. Defaults to True.
- **boundary**: str or None, optional
  Specifies whether the input signal is extended at both ends, and how to generate the new values, in order to center the first windowed segment on the first input point. This has the benefit of enabling reconstruction of the first input point when the employed window function starts at zero. Valid options are ['even', 'odd', 'constant', 'zeros', None]. Defaults to 'zeros', for zero padding extension. I.e. [1, 2, 3, 4] is extended to [0, 1, 2, 3, 4, 0] for nperseg=3.
- **padded**: bool, optional
  Specifies whether the input signal is zero-padded at the end to make the signal fit exactly into an integer number of window segments, so that all of the signal is included in the output. Defaults to True. Padding occurs after boundary extension, if boundary is not None, and padded is True, as is the default.
- **axis**: int, optional
  Axis along which the STFT is computed; the default is over the last axis (i.e. axis=-1).

**Returns**

- **f**: ndarray
  Array of sample frequencies.
- **t**: ndarray
  Array of segment times.
- **Zxx**: ndarray
STFT of \( x \). By default, the last axis of \( Z_{xx} \) corresponds to the segment times.

- `lombscargle`: Lomb-Scargle periodogram for unevenly sampled data

Notes

In order to enable inversion of an STFT via the inverse STFT in `istft`, the signal windowing must obey the constraint of “Constant OverLap Add” (COLA), and the input signal must have complete windowing coverage (i.e. \( (x.shape[axis] - nperseg) \% (nperseg-noverlap) == 0 \)). The `padded` argument may be used to accomplish this.

The COLA constraint ensures that every point in the input data is equally weighted, thereby avoiding aliasing and allowing full reconstruction. Whether a choice of `window`, `nperseg`, and `noverlap` satisfy this constraint can be tested with `check_COLA`.

New in version 0.19.0.

References

[R301], [R302]

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

Generate a test signal, a 2 Vrms sine wave whose frequency is slowly modulated around 3kHz, corrupted by white noise of exponentially decreasing magnitude sampled at 10 kHz.

```python
>>> fs = 10e3
>>> N = 1e5
>>> amp = 2 * np.sqrt(2)
>>> noise_power = 0.01 * fs / 2
>>> time = np.arange(N) / float(fs)
>>> mod = 500*np.cos(2*np.pi*0.25*time)
>>> carrier = amp * np.sin(2*np.pi*3e3*time + mod)
>>> noise = np.random.normal(scale=np.sqrt(noise_power), ... size=time.shape)
>>> noise *= np.exp(-time/5)
>>> x = carrier + noise
```

Compute and plot the STFT’s magnitude.

```python
>>> f, t, Zxx = signal.stft(x, fs, nperseg=1000)
>>> plt.pcolormesh(t, f, np.abs(Zxx), vmin=0, vmax=amp)
>>> plt.title('STFT Magnitude')
>>> plt.ylabel('Frequency [Hz]')
>>> plt.xlabel('Time [sec]')
>>> plt.show()
```
scipy.signal.istft(Zxx, fs=1.0, window='hann', nperseg=None, noverlap=None, nfft=None, input_onesided=True, boundary=True, time_axis=-1, freq_axis=-2)

Perform the inverse Short Time Fourier transform (iSTFT).

**Parameters**

- **Zxx**: array_like
  STFT of the signal to be reconstructed. If a purely real array is passed, it will be cast to a complex data type.

- **fs**: float, optional
  Sampling frequency of the time series. Defaults to 1.0.

- **window**: str or tuple or array_like, optional
  Desired window to use. If `window` is a string or tuple, it is passed to `get_window` to generate the window values, which are DFT-even by default. See `get_window` for a list of windows and required parameters. If `window` is array_like it will be used directly as the window and its length must be `nperseg`. Defaults to a Hann window. Must match the window used to generate the STFT for faithful inversion.

- **nperseg**: int, optional
  Number of data points corresponding to each STFT segment. This parameter must be specified if the number of data points per segment is odd, or if the STFT was padded via `nfft > nperseg`. If `None`, the value depends on the shape of `Zxx` and `input_onesided`. If `input_onesided` is `True`, `nperseg=2*(Zxx.shape[freq_axis] - 1)`. Otherwise, `nperseg=Zxx.shape[freq_axis]`. Defaults to `None`.

- **noverlap**: int, optional
  Number of points to overlap between segments. If `None`, half of the segment length. Defaults to `None`. When specified, the COLA constraint must be met (see Notes below), and should match the parameter used to generate the STFT. Defaults to `None`.

- **nfft**: int, optional
  Number of FFT points corresponding to each STFT segment. This parameter must be specified if the STFT was padded via `nfft > nperseg`. If `None`, the default values are the same as for `nperseg`, detailed above, with one exception: if `input_onesided` is `True` and `nperseg==2*Zxx.shape[freq_axis] - 1`, `nfft` also takes on that value. This case allows the proper inversion of an odd-length unpadded STFT using `nfft=None`. Defaults to `None`.
input_onesided : bool, optional
    If True, interpret the input array as one-sided FFTs, such as is returned by stft with return_onesided=True and numpy.fft.rfft. If False, interpret the input as a a two-sided FFT. Defaults to True.

boundary : bool, optional
    Specifies whether the input signal was extended at its boundaries by supplying a non-None boundary argument to stft. Defaults to True.

time_axis : int, optional
    Where the time segments of the STFT is located; the default is the last axis (i.e. axis=-1).

dfreq_axis : int, optional
    Where the frequency axis of the STFT is located; the default is the penultimate axis (i.e. axis=-2).

Returns

- t : ndarray
  Array of output data times.

- x : ndarray
  iSTFT of Zxx.

See also:

- stft  Short Time Fourier Transform
- check_COLA Check whether the Constant OverLap Add (COLA) constraint is met

Notes

In order to enable inversion of an STFT via the inverse STFT with istft, the signal windowing must obey the constraint of “Constant OverLap Add” (COLA). This ensures that every point in the input data is equally weighted, thereby avoiding aliasing and allowing full reconstruction. Whether a choice of window, nperseg, and noverlap satisfy this constraint can be tested with check_COLA, by using nperseg = Zxx.shape[dfreq_axis].

An STFT which has been modified (via masking or otherwise) is not guaranteed to correspond to a exactly realizable signal. This function implements the iSTFT via the least-squares estimation algorithm detailed in [R277], which produces a signal that minimizes the mean squared error between the STFT of the returned signal and the modified STFT.

New in version 0.19.0.

References

[R277], [R278]

Examples

```python
>>> from scipy import signal
>>> import matplotlib.pyplot as plt

Generate a test signal, a 2 Vrms sine wave at 50Hz corrupted by 0.001 V**2/Hz of white noise sampled at 1024 Hz.

```
```python

>>> x = carrier + noise

Compute the STFT, and plot its magnitude

```
Note that the cleaned signal does not start as abruptly as the original, since some of the coefficients of the transient were also removed:

```python
>>> plt.figure()
>>> plt.plot(time, x, time, xrec, time, carrier)
>>> plt.xlim([0, 0.1])
>>> plt.xlabel('Time [sec]')
>>> plt.ylabel('Signal')
>>> plt.legend(['Carrier + Noise', 'Filtered via STFT', 'True Carrier'])
>>> plt.show()
```

scipy.signal.check_COLA(window, nperseg, noverlap, tol=1e-10)

Check whether the Constant OverLap Add (COLA) constraint is met

**Parameters**

- **window**: str or tuple or array_like

  Desired window to use. If `window` is a string or tuple, it is passed to `get_window` to generate the window values, which are DFT-even by default. See `get_window` for a list of windows and required parameters. If
window is array_like it will be used directly as the window and its length must be nperseg.

nperseg : int
    Length of each segment.

noverlap : int
    Number of points to overlap between segments.

tol : float, optional
    The allowed variance of a bin’s weighted sum from the median bin sum.

Returns

verdict : bool
    True if chosen combination satisfies COLA within tol, False otherwise

See also:

stft  Short Time Fourier Transform

istft  Inverse Short Time Fourier Transform

Notes

In order to enable inversion of an STFT via the inverse STFT in istft, the signal windowing must obey the constraint of “Constant OverLap Add” (COLA). This ensures that every point in the input data is equally weighted, thereby avoiding aliasing and allowing full reconstruction.

Some examples of windows that satisfy COLA:

• Rectangular window at overlap of 0, 1/2, 2/3, 3/4, ...
• Bartlett window at overlap of 1/2, 3/4, 5/6, ...
• Hann window at 1/2, 2/3, 3/4, ...
• Any Blackman family window at 2/3 overlap
• Any window with noverlap = nperseg-1

A very comprehensive list of other windows may be found in [R243], wherein the COLA condition is satisfied when the “Amplitude Flatness” is unity.

New in version 0.19.0.

References

[R242], [R243]

Examples

>>> from scipy import signal

Confirm COLA condition for rectangular window of 75% (3/4) overlap:

>>> signal.check_COLA(signal.boxcar(100), 100, 75)
True

COLA is not true for 25% (1/4) overlap, though:

>>> signal.check_COLA(signal.boxcar(100), 100, 25)
False

“Symmetrical” Hann window (for filter design) is not COLA:

>>> signal.check_COLA(signal.hann(120, sym=True), 120, 60)
False

“Periodic” or “DFT-even” Hann window (for FFT analysis) is COLA for overlap of 1/2, 2/3, 3/4, etc.:

class scipy.sparse.bsr_matrix(arg1[, shape=None, dtype=None, copy=False, blocksize=None)

Block Sparse Row matrix

This can be instantiated in several ways:

- bsr_matrix(D, [blocksize=(R,C)])
  where D is a dense matrix or 2-D ndarray.
- bsr_matrix(S, [blocksize=(R,C)])
  with another sparse matrix S (equivalent to S.tobsr())
- bsr_matrix((M, N), [blocksize=(R,C), dtype])
  to construct an empty matrix with shape (M, N) dtype is optional, defaulting to dtype='d'.
- bsr_matrix((data, ijr), [blocksize=(R,C), shape=(M, N)])
  where data and ijr satisfy a[ijr[0, k], ijr[1, k]] = data[k]
- bsr_matrix((data, indices, indptr), [shape=(M, N)])
  is the standard BSR representation where the block column indices for row i are stored in indices[indptr[i]:indptr[i+1]] and their corresponding block values are stored in data[ indptr[i]: indptr[i+1] ]. If the shape parameter is not supplied, the matrix dimensions are inferred from the index arrays.
Notes

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

Summary of BSR format

The Block Compressed Row (BSR) format is very similar to the Compressed Sparse Row (CSR) format. BSR is appropriate for sparse matrices with dense sub matrices like the last example below. Block matrices often arise in vector-valued finite element discretizations. In such cases, BSR is considerably more efficient than CSR and CSC for many sparse arithmetic operations.

Blocksize

The blocksize (R,C) must evenly divide the shape of the matrix (M,N). That is, R and C must satisfy the relationship M % R = 0 and N % C = 0.

If no blocksize is specified, a simple heuristic is applied to determine an appropriate blocksize.

Examples

```python
>>> from scipy.sparse import bsr_matrix
>>> bsr_matrix((3, 4), dtype=np.int8).toarray()
array([[0, 0, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]], dtype=int8)
```

```python
>>> row = np.array([0, 0, 1, 2, 2, 2])
>>> col = np.array([0, 2, 2, 0, 1, 2])
>>> data = np.array([1, 2, 3, 4, 5, 6])
>>> bsr_matrix((data, (row, col)), shape=(3, 3)).toarray()
array([[1, 0, 2],
       [0, 0, 3],
       [4, 5, 6]])
```

```python
>>> indptr = np.array([0, 2, 3, 6])
>>> indices = np.array([0, 2, 2, 0, 1, 2])
>>> data = np.array([1, 2, 3, 4, 5, 6]).repeat(4).reshape(6, 2, 2)
>>> bsr_matrix((data, indices, indptr), shape=(6, 6)).toarray()
array([[1, 1, 0, 0, 2, 2],
       [1, 1, 0, 0, 2, 2],
       [0, 0, 0, 0, 3, 3],
       [0, 0, 0, 0, 3, 3],
       [4, 4, 5, 5, 6, 6],
       [4, 4, 5, 5, 6, 6]])
```

Attributes

- **shape**: Get shape of a matrix.
- **nnz**: Number of stored values, including explicit zeros.
- **has_sorted_indices**: Determine whether the matrix has sorted indices.

```python
bsr_matrix.shape
```
Get shape of a matrix.

```python
bsr_matrix.nnz
```
Number of stored values, including explicit zeros.
See also:

`count_nonzero`
Number of non-zero entries

`bsr_matrix.has_sorted_indices`
Determine whether the matrix has sorted indices

**Returns**

- True: if the indices of the matrix are in sorted order
- False: otherwise

<table>

</tr>
</tbody>
</table>

**Methods**

- `arcsin()` Element-wise arcsin.
- `arcsinh()` Element-wise arcsinh.
- `arctan()` Element-wise arctan.
- `arctanh()` Element-wise arctanh.
- `argmax([axis, out])` Return indices of maximum elements along an axis.
- `argmin([axis, out])` Return indices of minimum elements along an axis.
- `asformat(format)` Return this matrix in a given sparse format.
- `asfptype()` Upcast matrix to a floating point format (if necessary).
- `astype(dtype[, casting, copy])` Cast the matrix elements to a specified type.
- `ceil()` Element-wise ceil.
- `check_format([full_check])` Check whether the matrix format is valid.
- `conj()` Element-wise complex conjugation.
- `conjugate()` Element-wise complex conjugation.
- `copy()` Returns a copy of this matrix.
- `count_nonzero()` Number of non-zero entries, equivalent to `nnz`.
- `deg2rad()` Element-wise deg2rad.
- `diagonal([k])` Returns the k-th diagonal of the matrix.
- `dot(other)` Ordinary dot product.
- `eliminate_zeros()` Remove zero elements in-place.
- `expm1()` Element-wise expm1.
- `floor()` Element-wise floor.
- `getH()` Return the Hermitian transpose of this matrix.
- `get_shape()` Get shape of a matrix.
- `getcol(j)` Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).
- `getformat()` Format of a matrix representation as a string.
- `getmaxprint()` Maximum number of elements to display when printed.
- `getnnz([axis])` Number of stored values, including explicit zeros.
- `getrow(i)` Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).
- `log1p()` Element-wise log1p.
- `matmat(*args, **kwds)` `matmat` is deprecated!
- `matvec(*args, **kwds)` `matvec` is deprecated!

</tbody>
</table>

`bsr_matrix.arcsin()`  
Element-wise arcsin.  
See numpy.arcsin for more information.

`bsr_matrix.arcsinh()`  
Element-wise arcsinh.  
See numpy.arcsinh for more information.
bsr_matrix.arctan()  
Element-wise arctan.  
See numpy.arctan for more information.

bsr_matrix.arctanh()  
Element-wise arctanh.  
See numpy.arctanh for more information.

bsr_matrix.argmax(axis=None, out=None)  
Return indices of maximum elements along an axis.  
Implicit zero elements are also taken into account. If there are several maximum values, the index of the first occurrence is returned.

Parameters  
axis : {-2, -1, 0, 1, None}, optional  
Axis along which the argmax is computed. If None (default), index of the maximum element in the flatten data is returned.

out : None, optional  
This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns  
ind : np.matrix or int  
Indices of maximum elements. If matrix, its size along axis is 1.

bsr_matrix.argmin(axis=None, out=None)  
Return indices of minimum elements along an axis.  
Implicit zero elements are also taken into account. If there are several minimum values, the index of the first occurrence is returned.

Parameters  
axis : {-2, -1, 0, 1, None}, optional  
Axis along which the argmin is computed. If None (default), index of the minimum element in the flatten data is returned.

out : None, optional  
This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns  
ind : np.matrix or int  
Indices of minimum elements. If matrix, its size along axis is 1.

bsr_matrix.asformat(format)  
Return this matrix in a given sparse format

Parameters  
format : {string, None}  
desired sparse matrix format

• None for no format conversion  
• “csr” for csr_matrix format  
• “csc” for csc_matrix format  
• “lil” for lil_matrix format  
• “dok” for dok_matrix format and so on

bsr_matrix.asfptype()  
Upcast matrix to a floating point format (if necessary)

bsr_matrix.astype(dtype, casting='unsafe', copy=True)  
Cast the matrix elements to a specified type.

Parameters  
dtype : string or numpy dtype  
Typecode or data-type to which to cast the data.
casting : {'no', 'equiv', 'safe', 'same_kind', 'unsafe'}, optional
    Controls what kind of data casting may occur. Defaults to `unsafe` for backwards compatibility. `no` means the data types should not be cast at all. `equiv` means only byte-order changes are allowed. `safe` means only casts which can preserve values are allowed. `same_kind` means only safe casts or casts within a kind, like float64 to float32, are allowed. `unsafe` means any data conversions may be done.

copy : bool, optional
    If `copy` is `False`, the result might share some memory with this matrix. If `copy` is `True`, it is guaranteed that the result and this matrix do not share any memory.

bsr_matrix.ceil()
    Element-wise ceil.

    See numpy.ceil for more information.

bsr_matrix.check_format (full_check=True)
    check whether the matrix format is valid

    Parameters:
    full_check: True - rigorous check, O(N) operations : default False - basic check, O(1) operations

bsr_matrix.conj()
    Element-wise complex conjugation.

    If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

bsr_matrix.conjugate()
    Element-wise complex conjugation.

    If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

bsr_matrix.copy()
    Returns a copy of this matrix.

    No data/indices will be shared between the returned value and current matrix.

bsr_matrix.count_nonzero()
    Number of non-zero entries, equivalent to
    np.count_nonzero(a.toarray())

    Unlike getnnz() and the nnz property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

bsr_matrix.deg2rad()
    Element-wise deg2rad.

    See numpy.deg2rad for more information.

bsr_matrix.diagonal (k=0)
    Returns the k-th diagonal of the matrix.

    Parameters
    k : int, optional
        Which diagonal to set, corresponding to elements a[i, i+k]. Default: 0 (the main diagonal).

    See also:

    numpy.diagonal
        Equivalent numpy function.
Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```

bsr_matrix.dot(other)
Ordinary dot product

Examples

```python
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

bsr_matrix.eliminate_zeros()
Remove zero elements in-place.

bsr_matrix.expm1()
Element-wise \( \exp(1) \).

See `numpy.expm1` for more information.

bsr_matrix.floor()
Element-wise floor.

See `numpy.floor` for more information.

bsr_matrix.getH()
Return the Hermitian transpose of this matrix.

See also:

- `numpy.matrix.getH`
  NumPy’s implementation of \( \text{getH} \) for matrices

bsr_matrix.get_shape()
Get shape of a matrix.

bsr_matrix.getcol(j)
Returns a copy of column \( j \) of the matrix, as an \( (m \times 1) \) sparse matrix (column vector).

bsr_matrix.getformat()
Format of a matrix representation as a string.

bsr_matrix.getmaxprint()
Maximum number of elements to display when printed.

bsr_matrix.getnnz(axis=None)
Number of stored values, including explicit zeros.

Parameters:
- **axis**: None, 0, or 1
  Select between the number of values across the whole matrix, in each column, or in each row.

See also:
count_nonzero

Number of non-zero entries

bsr_matrix.getrow(i)

Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).

bsr_matrix.log1p()

Element-wise log1p.

See numpy.log1p for more information.

bsr_matrix.matmat(*args, **kwds)

Multiply this sparse matrix by other matrix.

bsr_matrix.matvec(*args, **kwds)

Multiply matrix by vector.

bsr_matrix.max(axis=None, out=None)

Return the maximum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

Parameters:
- axis : {-2, -1, 0, 1, None} optional
  Axis along which the sum is computed. The default is to compute the maximum over all the matrix elements, returning a scalar (i.e. axis = None).
- out : None, optional
  This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns:
- amax : coo_matrix or scalar
  Maximum of a. If axis is None, the result is a scalar value. If axis is given, the result is a sparse.coo_matrix of dimension a.ndim - 1.

See also:
- min
  The minimum value of a sparse matrix along a given axis.
- np.matrix.max
  NumPy’s implementation of ‘max’ for matrices

bsr_matrix.maximum(other)

Element-wise maximum between this and another matrix.

bsr_matrix.mean(axis=None, dtype=None, out=None)

Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. float64 intermediate and return values are used for integer inputs.

Parameters:
- axis : {-2, -1, 0, 1, None} optional
  Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e. axis = None).
- dtype : data-type, optional
  Type to use in computing the mean. For integer inputs, the default is float64; for floating point inputs, it is the same as the input dtype.
- out : np.matrix, optional
  Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.
Returns

m : np.matrix

See also:

np.matrix.mean

NumPy's implementation of ‘mean’ for matrices

bsr_matrix.min(axis=None, out=None)

Return the minimum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

Parameters

axis : {-2, -1, 0, 1, None} optional

Axis along which the sum is computed. The default is to compute the minimum over all the matrix elements, returning a scalar (i.e. axis = None).

out : None, optional

This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns

amin : coo_matrix or scalar

Minimum of a. If axis is None, the result is a scalar value. If axis is given, the result is a sparse.coo_matrix of dimension a.ndim - 1.

See also:

max

The maximum value of a sparse matrix along a given axis.

np.matrix.min

NumPy's implementation of ‘min’ for matrices

bsr_matrix.minimum(other)

Element-wise minimum between this and another matrix.

bsr_matrix.multiply(other)

Point-wise multiplication by another matrix, vector, or scalar.

bsr_matrix.nonzero()

called nonzero indices

Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1,2,0],[0,0,3],[4,0,5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

bsr_matrix.power(n, dtype=None)

This function performs element-wise power.

Parameters

n : n is a scalar
dtype : If dtype is not specified, the current dtype will be preserved.

bsr_matrix.prune()

Remove empty space after all non-zero elements.

bsr_matrix.rad2deg()

Element-wise rad2deg.

See numpy.rad2deg for more information.

bsr_matrix.reshape(shape, order='C')

Gives a new shape to a sparse matrix without changing its data.
Parameters

- **shape**: length-2 tuple of ints
  The new shape should be compatible with the original shape.
- **order**: ‘C’, optional
  This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns

- **reshaped_matrix**: *self* with the new dimensions of *shape*

See also:

- **np.matrix.reshape**: NumPy’s implementation of ‘reshape’ for matrices

*bsr_matrix.rint()*

Element-wise rint.

See numpy.rint for more information.

*bsr_matrix.set_shape(shape)*

See reshape.

*bsr_matrix.setdiag(values, k=0)*

Set diagonal or off-diagonal elements of the array.

Parameters

- **values**: array_like
  New values of the diagonal elements.
  Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values if longer than the diagonal, then the remaining values are ignored.
  If a scalar value is given, all of the diagonal is set to it.
- **k**: int, optional
  Which off-diagonal to set, corresponding to elements a[i,i+k]. Default: 0 (the main diagonal).

*bsr_matrix.sign()*

Element-wise sign.

See numpy.sign for more information.

*bsr_matrix.sin()*

Element-wise sin.

See numpy.sin for more information.

*bsr_matrix.sinh()*

Element-wise sinh.

See numpy.sinh for more information.

*bsr_matrix.sort_indices()*

Sort the indices of this matrix *in place*

*bsr_matrix.sorted_indices()*

Return a copy of this matrix with sorted indices

*bsr_matrix.sqrt()*

Element-wise sqrt.

See numpy.sqrt for more information.

*bsr_matrix.sum(axis=None, dtype=None, out=None)*

Sum the matrix elements over a given axis.

Parameters

- **axis**: {-2, -1, 0, 1, None} optional
Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e. axis = None).

**dtype**: dtype, optional

The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of a is used by default unless a has an integer dtype of less precision than the default platform integer. In that case, if a is signed then the platform integer is used while if a is unsigned then an unsigned integer of the same precision as the platform integer is used.

**out**: np.matrix, optional

Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

**Returns**

**sum_along_axis**: np.matrix

A matrix with the same shape as self, with the specified axis removed.

See also:

**np.matrix.sum**

NumPy’s implementation of ‘sum’ for matrices

**bsr_matrix.sum_duplicates()**

Eliminate duplicate matrix entries by adding them together

The is an in place operation

**bsr_matrix.tan()**

Element-wise tan.

See numpy.tan for more information.

**bsr_matrix.tanh()**

Element-wise tanh.

See numpy.tanh for more information.

**bsr_matrix.toarray(order=None, out=None)**

Return a dense ndarray representation of this matrix.

**Parameters**

**order**: {'C', 'F'}, optional

Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the out argument.

**out**: ndarray, 2-dimensional, optional

If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, out is required to be memory contiguous (either C or Fortran ordered).

**Returns**

**arr**: ndarray, 2-dimensional

An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If out was passed, the same object is returned after being modified in-place to contain the appropriate values.

**bsr_matrix.tobsr(blocksize=None, copy=False)**

Convert this matrix into Block Sparse Row Format.

With copy=False, the data/indices may be shared between this matrix and the resultant bsr_matrix.
If blocksize=(R, C) is provided, it will be used for determining block size of the bsr_matrix.

bsr_matrix.tocoo(copy=True)
Convert this matrix to COOrdinate format.

When copy=False the data array will be shared between this matrix and the resultant coo_matrix.

bsr_matrix.tocsc(copy=False)
Convert this matrix to Compressed Sparse Column format.

With copy=False, the data/indices may be shared between this matrix and the resultant csc_matrix.

bsr_matrix.tocsr(copy=False)
Convert this matrix to Compressed Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant csr_matrix.

bsr_matrix.todense(order=None, out=None)
Return a dense matrix representation of this matrix.

Parameters
order : {'C', 'F'}, optional
Whether to store multi-dimensional data in C (row-major) or Fortran
(column-major) order in memory. The default is 'None', indicating
the NumPy default of C-ordered. Cannot be specified in conjunction
with the out argument.

out : ndarray, 2-dimensional, optional
If specified, uses this array (or numpy.matrix) as the output buffer
instead of allocating a new array to return. The provided array must
have the same shape and dtype as the sparse matrix on which you are
calling the method.

Returns
arr : numpy.matrix, 2-dimensional
A NumPy matrix object with the same shape and containing the same
data represented by the sparse matrix, with the requested memory
order. If out was passed and was an array (rather than a numpy.
matrix), it will be filled with the appropriate values and returned
wrapped in a numpy.matrix object that shares the same memory.

bsr_matrix.todia(copy=False)
Convert this matrix to sparse DIAgonal format.

With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.

bsr_matrix.todok(copy=False)
Convert this matrix to Dictionary Of Keys format.

With copy=False, the data/indices may be shared between this matrix and the resultant dok_matrix.

bsr_matrix.tolil(copy=False)
Convert this matrix to LInked List format.

With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.

bsr_matrix.transpose(axes=None, copy=False)
Reverses the dimensions of the sparse matrix.

Parameters
axes : None, optional
This argument is in the signature solely for NumPy compatibility rea-
sons. Do not pass in anything except for the default value.

copy : bool, optional
Indicates whether or not attributes of self should be copied whenever
possible. The degree to which attributes are copied varies depending
on the type of sparse matrix being used.

Returns
p : self with the dimensions reversed.
See also:

np.matrix.transpose

NumPy's implementation of ‘transpose’ for matrices

bsr_matrix.trunc()

Element-wise trunc.

See numpy.trunc for more information.

class scipy.sparse.coo_matrix(arg1, shape=None, dtype=None, copy=False)

A sparse matrix in COOrdinate format.

Also known as the ‘ijv’ or ‘triplet’ format.

This can be instantiated in several ways:

    coo_matrix(D)

    with a dense matrix D

    coo_matrix(S) with another sparse matrix S (equivalent to S.tocoo())

    coo_matrix((M, N), [dtype])

    to construct an empty matrix with shape (M, N) dtype is optional, defaulting to
dtype='d'.

    coo_matrix((data, (i, j)), [shape=(M, N)])

    to construct from three arrays:

1. data[:] the entries of the matrix, in any order
2. i[: ] the row indices of the matrix entries
3. j[: ] the column indices of the matrix entries

Where A[i[k], j[k]] = data[k]. When shape is not specified, it is inferred from the index arrays

Notes

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

Advantages of the COO format

• facilitates fast conversion among sparse formats
• permits duplicate entries (see example)
• very fast conversion to and from CSR/CSC formats

Disadvantages of the COO format

• does not directly support:
  – arithmetic operations
  – slicing

Intended Usage

• COO is a fast format for constructing sparse matrices
• Once a matrix has been constructed, convert to CSR or CSC format for fast arith-
  metic and matrix vector operations
• By default when converting to CSR or CSC format, duplicate (i,j) entries will be
  summed together. This facilitates efficient construction of finite element matrices
  and the like. (see example)
**Examples**

```python
>>> # Constructing an empty matrix
>>> from scipy.sparse import coo_matrix
>>> coo_matrix((3, 4), dtype=np.int8).toarray()
array([[0, 0, 0, 0],
        [0, 0, 0, 0],
        [0, 0, 0, 0]], dtype=int8)

>>> # Constructing a matrix using ijv format
>>> row = np.array([0, 3, 1, 0])
>>> col = np.array([0, 3, 1, 2])
>>> data = np.array([4, 5, 7, 9])
>>> coo_matrix((data, (row, col)), shape=(4, 4)).toarray()
array([[4, 0, 9, 0],
        [0, 7, 0, 0],
        [0, 0, 0, 0],
        [0, 0, 0, 5]])

>>> # Constructing a matrix with duplicate indices
>>> row = np.array([0, 0, 1, 3, 1, 0, 0])
>>> col = np.array([0, 2, 1, 3, 1, 0, 0])
>>> data = np.array([1, 1, 1, 1, 1, 1, 1])
>>> coo = coo_matrix((data, (row, col)), shape=(4, 4))
>>> # Duplicate indices are maintained until implicitly or explicitly summed
>>> np.max(coo.data)
1
>>> coo.toarray()
array([[3, 0, 1, 0],
        [0, 2, 0, 0],
        [0, 0, 0, 0],
        [0, 0, 0, 1]])
```

**Attributes**

- `shape`: Get shape of a matrix.
- `nnz`: Number of stored values, including explicit zeros.

```python
coo_matrix.shape
Get shape of a matrix.
coo_matrix.nnz
Number of stored values, including explicit zeros.
```

**Methods**

- `dtype`: Data type of the matrix
- `ndim`: Number of dimensions (this is always 2)
- `data`: COO format data array of the matrix
- `row`: COO format row index array of the matrix
- `col`: COO format column index array of the matrix

**coo_matrix.arcsin()**

Element-wise arcsin.

See numpy.arcsin for more information.

**coo_matrix.arcsinh()**

Element-wise arcsinh.

See numpy.arcsinh for more information.

**coo_matrix.arctan()**

Element-wise arctan.

See numpy.arctan for more information.

**coo_matrix.arctanh()**

Element-wise arctanh.

See numpy.arctanh for more information.

**coo_matrix.argmax(axes=None, out=None)**

Return indices of maximum elements along an axis.

Implicit zero elements are also taken into account. If there are several maximum values, the index of the first occurrence is returned.

**Parameters**

- `axis`: {-2, -1, 0, 1, None}, optional
  - Axis along which the argmax is computed. If None (default), index of the maximum element in the flatten data is returned.

- `out`: None, optional
  - This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns**

- `ind`: np.matrix or int
  - Indices of maximum elements. If matrix, its size along axis is 1.

**coo_matrix.argmin(axes=None, out=None)**

Return indices of minimum elements along an axis.
Implicit zero elements are also taken into account. If there are several minimum values, the index of the first occurrence is returned.

**Parameters**
- `axis`: {-2, -1, 0, 1, None}, optional
  Axis along which the argmin is computed. If None (default), index of the minimum element in the flatten data is returned.
- `out`: None, optional
  This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns**
- `ind`: np.matrix or int
  Indices of minimum elements. If matrix, its size along `axis` is 1.

```python
coo_matrix.asformat(format)
```
Return this matrix in a given sparse format

**Parameters**
- `format`: {string, None}
  desired sparse matrix format
  - None for no format conversion
  - "csr" for csr_matrix format
  - "csc" for csc_matrix format
  - "lil" for lil_matrix format
  - "dok" for dok_matrix format and so on

```python
coo_matrix.asfptype()
```
Upcast matrix to a floating point format (if necessary)

```python
coo_matrix.astype(dtype, casting='unsafe', copy=True)
```
Cast the matrix elements to a specified type.

- `dtype`: string or numpy dtype
  Typecode or data-type to which to cast the data.
- `casting`: {'no', 'equiv', 'safe', 'same_kind', 'unsafe'}, optional
  Controls what kind of data casting may occur. Defaults to ‘unsafe’ for backwards compatibility. ‘no’ means the data types should not be cast at all. ‘equiv’ means only byte-order changes are allowed. ‘safe’ means only casts which can preserve values are allowed. ‘same_kind’ means only safe casts or casts within a kind, like float64 to float32, are allowed. ‘unsafe’ means any data conversions may be done.
- `copy`: bool, optional
  If `copy` is False, the result might share some memory with this matrix. If `copy` is True, it is guaranteed that the result and this matrix do not share any memory.

```python
coo_matrix.ceil()
```
Element-wise ceil.

See numpy.ceil for more information.

```python
coo_matrix.conj()
```
Element-wise complex conjugation.

If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

```python
coo_matrix.conjugate()
```
Element-wise complex conjugation.

If the matrix is of non-complex data type, then this method does nothing and the data is not copied.
coo_matrix.copy()

Returns a copy of this matrix.
No data/indices will be shared between the returned value and current matrix.

coo_matrix.count_nonzero()

Number of non-zero entries, equivalent to
np.count_nonzero(a.toarray())

Unlike getnnz() and the nnz property, which return the number of stored entries (the length of the data
attribute), this method counts the actual number of non-zero entries in data.

coo_matrix.deg2rad()

Element-wise deg2rad.
See numpy.deg2rad for more information.

coo_matrix.diagonal(k=0)

Returns the k-th diagonal of the matrix.

Parameters
k : int, optional
Which diagonal to set, corresponding to elements a[i, i+k]. Default: 0 (the main diagonal).

See also:
numpy.diagonal
Equivalent numpy function.

Examples

>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])

>>> A.diagonal()
array([1, 0, 5])

>>> A.diagonal(k=1)
array([2, 3])

coo_matrix.dot(other)

Ordinary dot product

Examples

>>> import numpy as np
>>> from scipy.sparse import csr_matrix

>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])

>>> v = np.array([1, 0, -1])

>>> A.dot(v)
array([1, -3, -1], dtype=int64)

coo_matrix.eliminate_zeros()

Remove zero entries from the matrix
This is an in-place operation

coo_matrix.expm1()

Element-wise expm1.
See numpy.expm1 for more information.
coo_matrix.floor()
Element-wise floor.
See numpy.floor for more information.

coop_matrix.getH()
Return the Hermitian transpose of this matrix.

See also:
np.matrix.getH
NumPy’s implementation of getH for matrices

coo_matrix.get_shape()
Get shape of a matrix.

coo_matrix.getcol(j)
Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).

coo_matrix.getformat()
Format of a matrix representation as a string.

coo_matrix.getmaxprint()
Maximum number of elements to display when printed.

coo_matrix.getnnz(axis=None)
Number of stored values, including explicit zeros.

Parameters
axis : None, 0, or 1
Select between the number of values across the whole matrix, in each column, or in each row.

See also:
count_nonzero
Number of non-zero entries

coo_matrix.getrow(i)
Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).

coo_matrix.log1p()
Element-wise log1p.
See numpy.log1p for more information.

coo_matrix.max(axis=None, out=None)
Return the maximum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

Parameters
axis : {-2, -1, 0, 1, None} optional
Axis along which the sum is computed. The default is to compute the maximum over all the matrix elements, returning a scalar (i.e. axis = None).
out : None, optional
This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns
amax : coo_matrix or scalar
Maximum of a. If axis is None, the result is a scalar value. If axis is given, the result is a sparse.coo_matrix of dimension a.ndim - 1.

See also:
min
The minimum value of a sparse matrix along a given axis.
np.matrix.max

NumPy’s implementation of ‘max’ for matrices

coo_matrix.maximum(other)

Element-wise maximum between this and another matrix.

coo_matrix.mean(axis=None, dtype=None, out=None)

Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. float64 intermediate and return values are used for integer inputs.

Parameters

- **axis**: {-2, -1, 0, 1, None} optional
  - Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e. axis = None).

- **dtype**: data-type, optional
  - Type to use in computing the mean. For integer inputs, the default is float64; for floating point inputs, it is the same as the input dtype.

- **out**: np.matrix, optional
  - Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

Returns

- **m**: np.matrix

See also:

np.matrix.mean

NumPy’s implementation of ‘mean’ for matrices

coo_matrix.min(axis=None, out=None)

Return the minimum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

Parameters

- **axis**: {-2, -1, 0, 1, None} optional
  - Axis along which the sum is computed. The default is to compute the minimum over all the matrix elements, returning a scalar (i.e. axis = None).

- **out**: None, optional
  - This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns

- **amin**: coo_matrix or scalar
  - Minimum of a. If axis is None, the result is a scalar value. If axis is given, the result is a sparse.coo_matrix of dimension a.ndim - 1.

See also:

- max
  - The maximum value of a sparse matrix along a given axis.

np.matrix.min

NumPy’s implementation of ‘min’ for matrices

coo_matrix.minimum(other)

Element-wise minimum between this and another matrix.

coo_matrix.multiply(other)

Point-wise multiplication by another matrix

coo_matrix.nonzero()

nonzero indices

Returns a tuple of arrays (row, col) containing the indices of the non-zero elements of the matrix.
**Examples**

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1,2,0],[0,0,3],[4,0,5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

**coo_matrix.power**(n, dtype=None)

This function performs element-wise power.

**Parameters**

- **n**: n is a scalar
- **dtype**: If dtype is not specified, the current dtype will be preserved.

**coo_matrix.rad2deg**()

Element-wise rad2deg.

See numpy.rad2deg for more information.

**coo_matrix.reshape**(shape, order='C')

Gives a new shape to a sparse matrix without changing its data.

**Parameters**

- **shape**: length-2 tuple of ints
  The new shape should be compatible with the original shape.
- **order**: 'C', optional
  This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns**

- **reshaped_matrix**: self with the new dimensions of shape

See also:

- **np.matrix.reshape**
  NumPy's implementation of 'reshape' for matrices

**coo_matrix.rint**()

Element-wise rint.

See numpy.rint for more information.

**coo_matrix.set_shape**(shape)

See reshape.

**coo_matrix.setdiag**(values, k=0)

Set diagonal or off-diagonal elements of the array.

**Parameters**

- **values**: array_like
  New values of the diagonal elements.
  Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values if longer than the diagonal, then the remaining values are ignored.
  If a scalar value is given, all of the diagonal is set to it.
- **k**: int, optional
  Which off-diagonal to set, corresponding to elements a[i,i+k]. Default: 0 (the main diagonal).

**coo_matrix.sign**()

Element-wise sign.

See numpy.sign for more information.

**coo_matrix.sin**()

Element-wise sin.
coo_matrix.sinh()
    Element-wise sinh.
    See numpy.sinh for more information.

coo_matrix.sqrt()
    Element-wise sqrt.
    See numpy.sqrt for more information.

coo_matrix.sum(axis=None, dtype=None, out=None)
    Sum the matrix elements over a given axis.

    Parameters
    axis : {-2, -1, 0, 1, None} optional
        Axis along which the sum is computed. The default is to compute the
        sum of all the matrix elements, returning a scalar (i.e. axis = None).
    dtype : dtype, optional
        The type of the returned matrix and of the accumulator in which the
        elements are summed. The dtype of a is used by default unless a has
        an integer dtype of less precision than the default platform integer.
        In that case, if a is signed then the platform integer is used while if
        a is unsigned then an unsigned integer of the same precision as the
        platform integer is used.
    out : np.matrix, optional
        Alternative output matrix in which to place the result. It must have
        the same shape as the expected output, but the type of the output
        values will be cast if necessary.

    Returns
    sum_along_axis : np.matrix
        A matrix with the same shape as self, with the specified axis removed.

    See also:
    np.matrix.sum
        NumPy’s implementation of ‘sum’ for matrices

coo_matrix.sum_duplicates()
    Eliminate duplicate matrix entries by adding them together
    This is an in place operation

coo_matrix.tan()
    Element-wise tan.
    See numpy.tan for more information.

coo_matrix.tanh()
    Element-wise tanh.
    See numpy.tanh for more information.

coo_matrix.todense(order=None, out=None)
    See the docstring for spmatrix.todense.

coo_matrix.tobsr(blocksize=None, copy=False)
    Convert this matrix to Block Sparse Row format.
    With copy=False, the data/indices may be shared between this matrix and the resultant bsr_matrix.
    When blocksize=(R, C) is provided, it will be used for construction of the bsr_matrix.
coo_matrix.tocoo(copy=False)
Convert this matrix to COOrdinate format.
With copy=False, the data/indices may be shared between this matrix and the resultant coo_matrix.

coo_matrix.tocsc(copy=False)
Convert this matrix to Compressed Sparse Column format
Duplicate entries will be summed together.

Examples

```python
>>> from numpy import array
>>> from scipy.sparse import coo_matrix
>>> row = array([0, 0, 1, 3, 1, 0, 0])
>>> col = array([0, 2, 1, 3, 1, 0, 0])
>>> data = array([1, 1, 1, 1, 1, 1, 1])
>>> A = coo_matrix((data, (row, col)), shape=(4, 4)).tocsc()
>>> A.toarray()
array([[3, 0, 1, 0],
       [0, 2, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 1]])
```

coo_matrix.tocsr(copy=False)
Convert this matrix to Compressed Sparse Row format
Duplicate entries will be summed together.

Examples

```python
>>> from numpy import array
>>> from scipy.sparse import coo_matrix
>>> row = array([0, 0, 1, 3, 1, 0, 0])
>>> col = array([0, 2, 1, 3, 1, 0, 0])
>>> data = array([1, 1, 1, 1, 1, 1, 1])
>>> A = coo_matrix((data, (row, col)), shape=(4, 4)).tocsr()
>>> A.toarray()
array([[3, 0, 1, 0],
       [0, 2, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 1]])
```

coo_matrix.todense(order=None, out=None)
Return a dense matrix representation of this matrix.

Parameters

- **order**: {'C', 'F'}, optional
  Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the out argument.

- **out**: ndarray, 2-dimensional, optional
  If specified, uses this array (or numpy.matrix) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

Returns

- **arr**: numpy.matrix, 2-dimensional
  A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order.

5.21. Sparse matrices (scipy.sparse)
order. If out was passed and was an array (rather than a numpy.
matrix), it will be filled with the appropriate values and returned
wrapped in a numpy.matrix object that shares the same memory.

coo_matrix.todia(copy=False)
Convert this matrix to sparse DIAgonal format.

With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.

coo_matrix.todok(copy=False)
Convert this matrix to Dictionary Of Keys format.

With copy=False, the data/indices may be shared between this matrix and the resultant dok_matrix.

coo_matrix.tolil(copy=False)
Convert this matrix to LInked List format.

With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.

coo_matrix.transpose(axes=None, copy=False)
Reverses the dimensions of the sparse matrix.

Parameters
axes : None, optional
This argument is in the signature solely for NumPy compatibility rea-
sons. Do not pass in anything except for the default value.

copy : bool, optional
Indicates whether or not attributes of self should be copied whenever
possible. The degree to which attributes are copied varies depending
on the type of sparse matrix being used.

Returns
p : self with the dimensions reversed.

See also:
np.matrix.transpose
NumPy’s implementation of ‘transpose’ for matrices

coo_matrix.trunc()
Element-wise trunc.

See numpy.trunc for more information.

class scipy.sparse.csc_matrix(arg1, shape=None, dtype=None, copy=False)
Compressed Sparse Column matrix

This can be instantiated in several ways:

csc_matrix(D) with a dense matrix or rank-2 ndarray D
csc_matrix(S) with another sparse matrix S (equivalent to S.tocsc())
csc_matrix((M, N), [dtype])
to construct an empty matrix with shape (M, N) dtype is optional, defaulting to dtype=’d’.
csc_matrix((data, (row_ind, col_ind)), [shape=(M, N)])
where data, row_ind and col_ind satisfy the relationship a[row_ind[k],
col_ind[k]] = data[k]
csc_matrix((data, indices, indptr), [shape=(M, N)])
is the standard CSC representation where the row indices for column i are stored in
indices[indptr[i]:indptr[i+1]] and their corresponding values are stored in
data[indptr[i]:indptr[i+1]]. If the shape parameter is not supplied, the matrix
dimensions are inferred from the index arrays.

Notes
Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division,
and matrix power.
Advantages of the CSC format

- efficient arithmetic operations CSC + CSC, CSC * CSC, etc.
- efficient column slicing
- fast matrix vector products (CSR, BSR may be faster)

Disadvantages of the CSC format

- slow row slicing operations (consider CSR)
- changes to the sparsity structure are expensive (consider LIL or DOK)

Examples

```python
>>> import numpy as np
>>> from scipy.sparse import csc_matrix

>>> csc_matrix((3, 4), dtype=np.int8).toarray()
array([[0, 0, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]], dtype=int8)

>>> row = np.array([0, 2, 2, 0, 1, 2])
>>> col = np.array([0, 0, 1, 2, 2, 2])
>>> data = np.array([1, 2, 3, 4, 5, 6])
>>> csc_matrix((data, (row, col)), shape=(3, 3)).toarray()
array([[1, 0, 4],
       [0, 0, 5],
       [2, 3, 6]])

>>> indptr = np.array([0, 2, 3, 6])
>>> indices = np.array([0, 2, 2, 0, 1, 2])
>>> data = np.array([1, 2, 3, 4, 5, 6])
>>> csc_matrix((data, indices, indptr), shape=(3, 3)).toarray()
array([[1, 0, 4],
       [0, 0, 5],
       [2, 3, 6]])
```

```
csc_matrix.shape
Get shape of a matrix.

csc_matrix.nnz
Number of stored values, including explicit zeros.

See also:

count_nonzero
Number of non-zero entries

csc_matrix.has_sorted_indices
Determine whether the matrix has sorted indices

Returns

• True: if the indices of the matrix are in sorted order
```
• False: otherwise

<table>

Methods

- `arcsin()` Element-wise arcsin.
- `arcsinh()` Element-wise arcsinh.
- `arctan()` Element-wise arctan.
- `arctanh()` Element-wise arctanh.
- `argmax([axis, out])` Return indices of maximum elements along an axis.
- `argmin([axis, out])` Return indices of minimum elements along an axis.
- `asformat(format)` Return this matrix in a given sparse format.
- `asfptype()` Upcast matrix to a floating point format (if necessary)
- `astype(dtype[, casting, copy])` Cast the matrix elements to a specified type.
- `ceil()` Element-wise ceil.
- `check_format([full_check])` check whether the matrix format is valid
- `conj()` Element-wise complex conjugation.
- `conjugate()` Element-wise complex conjugation.
- `copy()` Returns a copy of this matrix.
- `count_nonzero()` Number of non-zero entries, equivalent to
- `deg2rad()` Element-wise deg2rad.
- `diagonal([k])` Returns the k-th diagonal of the matrix.
- `dot(other)` Ordinary dot product
- `eliminate_zeros()` Remove zero entries from the matrix
- `expm1()` Element-wise expm1.
- `floor()` Element-wise floor.
- `getH()` Return the Hermitian transpose of this matrix.
- `get_shape()` Get shape of a matrix.
- `getcol(i)` Returns a copy of column i of the matrix, as a (m x 1) CSC matrix (column vector).
- `getformat()` Format of a matrix representation as a string.
- `getmaxprint()` Maximum number of elements to display when printed.
- `getnnz([axis])` Number of stored values, including explicit zeros.
- `getrow(i)` Returns a copy of row i of the matrix, as a (1 x n) CSR matrix (row vector).
- `log1p()` Element-wise log1p.
- `max([axis, out])` Return the maximum of the matrix or maximum along an axis.
- `maximum(other)` Element-wise maximum between this and another matrix.
- `mean([axis, dtype, out])` Compute the arithmetic mean along the specified axis.
- `min([axis, out])` Return the minimum of the matrix or maximum along an axis.
- `minimum(other)` Element-wise minimum between this and another matrix.
- `multiply(other)` Point-wise multiplication by another matrix, vector, or scalar.

#### csc_matrix.arcsin()

Element-wise arcsin.

See numpy.arcsin for more information.

#### csc_matrix.arcsinh()

Element-wise arcsinh.

See numpy.arcsinh for more information.

#### csc_matrix.arctan()

Element-wise arctan.

See numpy.arctan for more information.

#### csc_matrix.arctanh()

Element-wise arctanh.

See numpy.arctanh for more information.

#### csc_matrix.argmax(

Return indices of maximum elements along an axis.
Implicit zero elements are also taken into account. If there are several maximum values, the index of the first occurrence is returned.

**Parameters**
- `axis`: {-2, -1, 0, 1, None}, optional
  - Axis along which the argmax is computed. If None (default), index of the maximum element in the flatten data is returned.
- `out`: None, optional
  - This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns**
- `ind`: np.matrix or int
  - Indices of maximum elements. If matrix, its size along `axis` is 1.

csc_matrix.argmin(axis=None, out=None)

Return indices of minimum elements along an axis.

Implicit zero elements are also taken into account. If there are several minimum values, the index of the first occurrence is returned.

**Parameters**
- `axis`: {-2, -1, 0, 1, None}, optional
  - Axis along which the argmin is computed. If None (default), index of the minimum element in the flatten data is returned.
- `out`: None, optional
  - This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns**
- `ind`: np.matrix or int
  - Indices of minimum elements. If matrix, its size along `axis` is 1.

csc_matrix.asformat(format)

Return this matrix in a given sparse format

**Parameters**
- `format`: {string, None}
  - desired sparse matrix format
  - •None for no format conversion
  - •"csr" for csr_matrix format
  - •"csc" for csc_matrix format
  - •"lil" for lil_matrix format
  - •"dok" for dok_matrix format and so on

**csc_matrix.asfptype**

Upcast matrix to a floating point format (if necessary)

csc_matrix.astype(dtype, casting='unsafe', copy=True)

Cast the matrix elements to a specified type.

**Parameters**
- `dtype`: string or numpy dtype
  - Typecode or data-type to which to cast the data.
- `casting`: {'no', 'equiv', 'safe', 'same_kind', 'unsafe'}, optional
  - Controls what kind of data casting may occur. Defaults to 'unsafe' for backwards compatibility. 'no' means the data types should not be cast at all. 'equiv' means only byte-order changes are allowed. 'safe' means only casts which can preserve values are allowed. 'same_kind' means only safe casts or casts within a kind, like float64 to float32, are allowed. 'unsafe' means any data conversions may be done.
- `copy`: bool, optional
If `copy` is `False`, the result might share some memory with this matrix. If `copy` is `True`, it is guaranteed that the result and this matrix do not share any memory.

csc_matrix.ceil()
Element-wise ceil.

See numpy.ceil for more information.

csc_matrix.check_format (full_check=True)
check whether the matrix format is valid

Parameters  
```
full_check : bool, optional
```
If `True`, rigorous check, O(N) operations. Otherwise basic check, O(1) operations (default True).

csc_matrix.conj()
Element-wise complex conjugation.

If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

csc_matrix.conjugate()
Element-wise complex conjugation.

If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

csc_matrix.copy()
Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

csc_matrix.count_nonzero()
Number of non-zero entries, equivalent to
`np.count_nonzero(a.toarray())`

Unlike getnnz() and the nnz property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

csc_matrix.deg2rad()
Element-wise deg2rad.

See numpy.deg2rad for more information.

csc_matrix.diagonal (k=0)
Returns the k-th diagonal of the matrix.

Parameters  
```
k : int, optional
```
Which diagonal to set, corresponding to elements a[i, i+k]. Default: 0 (the main diagonal).

See also:
```
numpy.diagonal
Equivalente numpy function.
```

Examples
```
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```

5.21. Sparse matrices (`scipy.sparse`)
scipy.sparse.csc_matrix

.. currentmodule:: scipy.sparse

.. autosummary:: csc_matrix

.. toctree::
   :maxdepth: 1

   csc_matrix.dot
   csc_matrix.eliminate_zeros
   csc_matrix.expm1
   csc_matrix.floor
   csc_matrix.getH
   csc_matrix.get_shape
   csc_matrix.getcol
   csc_matrix.getformat
   csc_matrix.getmaxprint
   csc_matrix.getnnz
   csc_matrix.getrow

.. _csc_matrix.

.. _csc_matrix.dot:

.. currentmodule:: scipy.sparse

csc_matrix.\dot (other)

Ordinary dot product

**Examples**

.. literalinclude:: examples/example13-matrix_dot.py
   :language: python

.. _csc_matrix.eliminate_zeros:

csc_matrix.eliminate_zeros()

Remove zero entries from the matrix

This is an in place operation

.. _csc_matrix.expm1:

csc_matrix.expm1()

Element-wise expm1.

See numpy.expm1 for more information.

.. _csc_matrix.floor:

csc_matrix.floor()

Element-wise floor.

See numpy.floor for more information.

.. _csc_matrix.getH:

csc_matrix.getH()

Return the Hermitian transpose of this matrix.

See also:

- :func:`numpy.matrix.getH`
  
  NumPy's implementation of getH for matrices

.. _csc_matrix.get_shape:

csc_matrix.get_shape()

Get shape of a matrix.

.. _csc_matrix.getcol:

csc_matrix.getcol(i)

Returns a copy of column i of the matrix, as a (m x 1) CSC matrix (column vector).

.. _csc_matrix.getformat:

csc_matrix.getformat()

Format of a matrix representation as a string.

.. _csc_matrix.getmaxprint:

csc_matrix.getmaxprint()

Maximum number of elements to display when printed.

.. _csc_matrix.getnnz:

csc_matrix.getnnz (axis=None)

Number of stored values, including explicit zeros.

**Parameters**

- axis : None, 0, or 1

  Select between the number of values across the whole matrix, in each column, or in each row.

See also:

- :func:`numpy.count_nonzero`

  Number of non-zero entries

.. _csc_matrix.getrow:

csc_matrix.getrow(i)

Returns a copy of row i of the matrix, as a (1 x n) CSR matrix (row vector).
csc_matrix.{\texttt{log1p}()}  
Element-wise log1p.

See {\texttt{numpy.log1p}} for more information.

csc_matrix.{\texttt{max}}(\texttt{axis=None, out=None})  
Return the maximum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

\begin{verbatim}
Parameters
  axis : {-2, -1, 0, 1, None} optional
    Axis along which the sum is computed. The default is to compute the maximum over all the matrix elements, returning a scalar (i.e. \texttt{axis = None}).

  out : None, optional
    This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns
  amax : coo_matrix or scalar
    Maximum of \texttt{a}. If \texttt{axis} is None, the result is a scalar value. If \texttt{axis} is given, the result is a sparse.coo_matrix of dimension \texttt{a.ndim - 1}.
\end{verbatim}

See also:

\texttt{min}  
The minimum value of a sparse matrix along a given axis.

\texttt{np.matrix.max}

NumPy’s implementation of ‘max’ for matrices

csc_matrix.{\texttt{maximum}}(\texttt{other})  
Element-wise maximum between this and another matrix.

csc_matrix.{\texttt{mean}}(\texttt{axis=None, dtype=None, out=None})  
Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. {\texttt{float64}} intermediate and return values are used for integer inputs.

\begin{verbatim}
Parameters
  axis : {-2, -1, 0, 1, None} optional
    Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e. \texttt{axis = None}).

  dtype : data-type, optional
    Type to use in computing the mean. For integer inputs, the default is \texttt{float64}; for floating point inputs, it is the same as the input dtype.

  out : np.matrix, optional
    Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

Returns
  m : np.matrix
\end{verbatim}

See also:

\texttt{np.matrix.mean}

NumPy’s implementation of ‘mean’ for matrices

csc_matrix.{\texttt{min}}(\texttt{axis=None, out=None})  
Return the minimum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

\begin{verbatim}
Parameters
  axis : {-2, -1, 0, 1, None} optional
    Axis along which the sum is computed. The default is to compute the minimum over all the matrix elements, returning a scalar (i.e. \texttt{axis = None}).
\end{verbatim}
out : None, optional

This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns

amin : coo_matrix or scalar

Minimum of a. If axis is None, the result is a scalar value. If axis is given, the result is a sparse.coo_matrix of dimension a.ndim - 1.

See also:

max

The maximum value of a sparse matrix along a given axis.

np.matrix.min

NumPy’s implementation of ‘min’ for matrices

csc_matrix.minimum(other)

Element-wise minimum between this and another matrix.

csc_matrix.multiply(other)

Point-wise multiplication by another matrix, vector, or scalar.

csc_matrix.nonzero()

nonzero indices

Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1,2,0],[0,0,3],[4,0,5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

csc_matrix.power(n, dtype=None)

This function performs element-wise power.

Parameters

n : n is a scalar
dtype : If dtype is not specified, the current dtype will be preserved.

csc_matrix.prune()

Remove empty space after all non-zero elements.

csc_matrix.rad2deg()

Element-wise rad2deg.

See numpy.rad2deg for more information.

csc_matrix.reshape(shape, order='C')

Gives a new shape to a sparse matrix without changing its data.

Parameters

shape : length-2 tuple of ints

The new shape should be compatible with the original shape.

order : ‘C’, optional

This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns

reshaped_matrix : self with the new dimensions of shape

See also:

np.matrix.reshape

NumPy’s implementation of ‘reshape’ for matrices
csc_matrix.rint()
Element-wise rint.
See numpy.rint for more information.

csc_matrix.set_shape(shape)
See reshape.

csc_matrix.setdiag(values, k=0)
Set diagonal or off-diagonal elements of the array.

Parameters
values : array_like
New values of the diagonal elements.
Values may have any length. If the diagonal is longer than values,
then the remaining diagonal entries will not be set. If values if longer
than the diagonal, then the remaining values are ignored.
If a scalar value is given, all of the diagonal is set to it.
k : int, optional
Which off-diagonal to set, corresponding to elements a[i,i+k]. Default: 0 (the main diagonal).

csc_matrix.sign()
Element-wise sign.
See numpy.sign for more information.

csc_matrix.sin()
Element-wise sin.
See numpy.sin for more information.

csc_matrix.sinh()
Element-wise sinh.
See numpy.sinh for more information.

csc_matrix.sort_indices()
Sort the indices of this matrix in place

csc_matrix.sorted_indices()
Return a copy of this matrix with sorted indices

csc_matrix.sqrt()
Element-wise sqrt.
See numpy.sqrt for more information.

csc_matrix.sum(axis=None, dtype=None, out=None)
Sum the matrix elements over a given axis.

Parameters
axis : {-2, -1, 0, 1, None} optional
Axis along which the sum is computed. The default is to compute the
sum of all the matrix elements, returning a scalar (i.e. axis = None).
dtype : dtype, optional
The type of the returned matrix and of the accumulator in which the
elements are summed. The dtype of a is used by default unless a has
an integer dtype of less precision than the default platform integer.
In that case, if a is signed then the platform integer is used while if
a is unsigned then an unsigned integer of the same precision as the
platform integer is used.
out : np.matrix, optional
Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

**Returns**

`sum_along_axis` : `np.matrix`

A matrix with the same shape as `self`, with the specified axis removed.

See also:

`np.matrix.sum`

NumPy’s implementation of ‘sum’ for matrices

csc_matrix.sum_duplicates()

Eliminate duplicate matrix entries by adding them together

The is an in place operation

csc_matrix.tan()

Element-wise tan.

See `numpy.tan` for more information.

csc_matrix.tanh()

Element-wise tanh.

See `numpy.tanh` for more information.

csc_matrix.toarray(order=None, out=None)

Return a dense ndarray representation of this matrix.

**Parameters**

*order* : {‘C’, ‘F’}, optional

Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the `out` argument.

*out* : `ndarray`, 2-dimensional, optional

If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, `out` is required to be memory contiguous (either C or Fortran ordered).

**Returns**

*arr* : `ndarray`, 2-dimensional

An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If `out` was passed, the same object is returned after being modified in-place to contain the appropriate values.

csc_matrix.tobsr(blocksize=None, copy=False)

Convert this matrix to Block Sparse Row format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant bsr_matrix.

When `blocksize=(R, C)` is provided, it will be used for construction of the bsr_matrix.

csc_matrix.tocoo(copy=True)

Convert this matrix to COOrdinate format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant coo_matrix.

csc_matrix.tocsc(copy=False)

Convert this matrix to Compressed Sparse Column format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant csc_matrix.
csc_matrix.tocsr(copy=False)
  Convert this matrix to Compressed Sparse Row format.

  With copy=False, the data/indices may be shared between this matrix and the resultant csr_matrix.

csc_matrix.todense(order=None, out=None)
  Return a dense matrix representation of this matrix.

  Parameters
  order : {'C', 'F'}, optional
    Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the out argument.

  out : ndarray, 2-dimensional, optional
    If specified, uses this array (or numpy.matrix) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

  Returns
  arr : numpy.matrix, 2-dimensional
    A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If out was passed and was an array (rather than a numpy.matrix), it will be filled with the appropriate values and returned wrapped in a numpy.matrix object that shares the same memory.

csc_matrix.todia(copy=False)
  Convert this matrix to sparse DIAgonal format.

  With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.

csc_matrix.todok(copy=False)
  Convert this matrix to Dictionary Of Keys format.

  With copy=False, the data/indices may be shared between this matrix and the resultant dok_matrix.

csc_matrix.tolil(copy=False)
  Convert this matrix to LInked List format.

  With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.

csc_matrix.transpose(axes=None, copy=False)
  Reverses the dimensions of the sparse matrix.

  Parameters
  axes : None, optional
    This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value.

  copy : bool, optional
    Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

  Returns
  p : self with the dimensions reversed.

  See also:

  np.matrix.transpose
    NumPy’s implementation of ‘transpose’ for matrices

csc_matrix.trunc()
  Element-wise trunc.

  See numpy.trunc for more information.
class scipy.sparse.csr_matrix(arg1, shape=None, dtype=None, copy=False)

Compressed Sparse Row matrix

This can be instantiated in several ways:

- `csr_matrix(D)` with a dense matrix or rank-2 ndarray D
- `csr_matrix(S)` with another sparse matrix S (equivalent to S.tocsr())
- `csr_matrix((M, N), [dtype])`
  to construct an empty matrix with shape (M, N) dtype is optional, defaulting to dtype='d'.
- `csr_matrix((data, (row_ind, col_ind)), [shape=(M, N))]`
  where data, row_ind and col_ind satisfy the relationship
  a[row_ind[k], col_ind[k]] = data[k].
- `csr_matrix((data, indices, indptr), [shape=(M, N)])`
  is the standard CSR representation where the column indices for row i are stored in
  indices[indptr[i]:indptr[i+1]] and their corresponding values are stored in
  data[indptr[i]:indptr[i+1]]. If the shape parameter is not
  supplied, the matrix dimensions are inferred from the index arrays.

Notes

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

Advantages of the CSR format

- efficient arithmetic operations CSR + CSR, CSR * CSR, etc.
- efficient row slicing
- fast matrix vector products

Disadvantages of the CSR format

- slow column slicing operations (consider CSC)
- changes to the sparsity structure are expensive (consider LIL or DOK)

Examples

```python
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> csr_matrix((3, 4), dtype=np.int8).toarray()
array([[0, 0, 0, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]], dtype=int8)

>>> row = np.array([0, 0, 1, 2, 2, 2])
>>> col = np.array([0, 2, 2, 0, 1, 2])
>>> data = np.array([1, 2, 3, 4, 5, 6])
>>> csr_matrix((data, (row, col)), shape=(3, 3)).toarray()
array([[1, 0, 2],
       [0, 0, 3],
       [4, 5, 6]])

>>> indptr = np.array([0, 2, 3, 6])
>>> indices = np.array([0, 2, 2, 0, 1, 2])
>>> data = np.array([1, 2, 3, 4, 5, 6])
>>> csr_matrix((data, indices, indptr), shape=(3, 3)).toarray()
array([[1, 0, 2],
       [0, 0, 3],
       [4, 5, 6]])
```
As an example of how to construct a CSR matrix incrementally, the following snippet builds a term-document matrix from texts:

```python
>>> docs = ["hello", "world", "hello"], ["goodbye", "cruel", "world"]
>>> indptr = [0]
>>> indices = []
>>> data = []
>>> vocabulary = {}
>>> for d in docs:
...     for term in d:
...         index = vocabulary.setdefault(term, len(vocabulary))
...         indices.append(index)
...         data.append(1)
...         indptr.append(len(indices))
...
array([[2, 1, 0, 0],
       [1, 1, 1, 1]])
```

### Attributes

```python
csr_matrix.arcsin()  # Element-wise arcsin.
    See numpy.arcsin for more information.

csr_matrix.arcsinh()  # Element-wise arcsinh.
    See numpy.arcsinh for more information.

csr_matrix.arctan()  # Element-wise arctan.
    See numpy.arctan for more information.

csr_matrix.arctanh()  # Element-wise arctanh.
    See numpy.arctanh for more information.

csr_matrix.argmax(axis=None, out=None)  # Return indices of maximum elements along an axis.
    Implicit zero elements are also taken into account. If there are several maximum values, the index of the first occurrence is returned.

    Parameters
    ----------
    axis : {-2, -1, 0, 1, None}, optional
        Axis along which the argmax is computed. If None (default), index of the maximum element in the flatten data is returned.

    out : None, optional
        This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

    Returns
    -------
    ind : np.matrix or int
        Indices of maximum elements. If matrix, its size along axis is 1.

csr_matrix.argmin(axis=None, out=None)  # Return indices of minimum elements along an axis.
```

5.21. Sparse matrices (scipy.sparse)
Implicit zero elements are also taken into account. If there are several minimum values, the index of the first occurrence is returned.

**Parameters**

axis : {-2, -1, 0, 1, None}, optional

Axis along which the argmin is computed. If None (default), index of the minimum element in the flatten data is returned.

out : None, optional

This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns**

ind : np.matrix or int

Indices of minimum elements. If matrix, its size along axis is 1.

csr_matrix.asformat(format)

Return this matrix in a given sparse format

**Parameters**

format : {string, None}

desired sparse matrix format

•None for no format conversion
•"csr" for csr_matrix format
•"csc" for csc_matrix format
•"lil" for lil_matrix format
•"dok" for dok_matrix format and so on

csr_matrix.asfptype()

Upcast matrix to a floating point format (if necessary)

csr_matrix.astype(dtype, casting='unsafe', copy=True)

Cast the matrix elements to a specified type.

**Parameters**

dtype : string or numpy dtype

Typecode or data-type to which to cast the data.

casting : {'no', 'equiv', 'safe', 'same_kind', 'unsafe'}, optional

Controls what kind of data casting may occur. Defaults to ‘unsafe’ for backwards compatibility. ‘no’ means the data types should not be cast at all. ‘equiv’ means only byte-order changes are allowed. ‘safe’ means only casts which can preserve values are allowed. ‘same_kind’ means only safe casts or casts within a kind, like float64 to float32, are allowed. ‘unsafe’ means any data conversions may be done.

copy : bool, optional

If copy is False, the result might share some memory with this matrix. If copy is True, it is guaranteed that the result and this matrix do not share any memory.

csr_matrix.ceil()

Element-wise ceil.

See numpy.ceil for more information.

csr_matrix.check_format(full_check=True)

check whether the matrix format is valid

**Parameters**

full_check : bool, optional

If True, rigorous check, O(N) operations. Otherwise basic check, O(1) operations (default True).

csr_matrix.conj()

Element-wise complex conjugation.
If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

csr_matrix.conjugate()
Element-wise complex conjugation.

If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

csr_matrix.copy()
Returns a copy of this matrix.
No data/indices will be shared between the returned value and current matrix.

csr_matrix.count_nonzero()
Number of non-zero entries, equivalent to
np.count_nonzero(a.toarray())
Unlike getnnz() and the nnz property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

csr_matrix.deg2rad()
Element-wise deg2rad.
See numpy.deg2rad for more information.

csr_matrix.diagonal(k=0)
Returns the k-th diagonal of the matrix.

Parameters
k : int, optional
Which diagonal to set, corresponding to elements a[i, i+k]. Default: 0 (the main diagonal).

See also:
numpy.diagonal
Equivalent numpy function.

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```

csr_matrix.dot(other)
Ordinary dot product

Examples

```python
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

csr_matrix.eliminate_zeros()
Remove zero entries from the matrix
This is an in place operation

5.21. Sparse matrices (scipy.sparse)
csr_matrix.
\texttt{expm1}()
Element-wise expm1.
See \texttt{numpy.expm1} for more information.

csr_matrix.
\texttt{floor}()
Element-wise floor.
See \texttt{numpy.floor} for more information.

csr_matrix.
\texttt{getH}()
Return the Hermitian transpose of this matrix.
\texttt{See also:}
\texttt{np.matrix.getH}
NumPy's implementation of \texttt{getH} for matrices

csr_matrix.
\texttt{get_shape}()
Get shape of a matrix.

csr_matrix.
\texttt{getcol}(i)
Returns a copy of column \(i\) of the matrix, as a \((m \times 1)\) CSR matrix (column vector).

csr_matrix.
\texttt{getformat}()
Format of a matrix representation as a string.

csr_matrix.
\texttt{getmaxprint}()
Maximum number of elements to display when printed.

csr_matrix.
\texttt{getnnz}(axis=None)
Number of stored values, including explicit zeros.
\texttt{Parameters}
\begin{itemize}
  \item \texttt{axis}: \texttt{None}, \texttt{0}, or \texttt{1}
\end{itemize}
Select between the number of values across the whole matrix, in each column, or in each row.

\texttt{See also:}
\texttt{count_nonzero}
Number of non-zero entries

csr_matrix.
\texttt{getrow}(i)
Returns a copy of row \(i\) of the matrix, as a \((1 \times n)\) CSR matrix (row vector).

csr_matrix.
\texttt{log1p}()
Element-wise log1p.
See \texttt{numpy.log1p} for more information.

csr_matrix.
\texttt{max}(axis=None, out=None)
Return the maximum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.
\texttt{Parameters}
\begin{itemize}
  \item \texttt{axis}: \{-2, -1, 0, 1, \texttt{None}\} \texttt{optional}
    Axis along which the sum is computed. The default is to compute the maximum over all the matrix elements, returning a scalar (i.e. \texttt{axis} = \texttt{None}).
  \item \texttt{out}: \texttt{None}, \texttt{optional}
    This argument is in the signature \textit{solely} for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.
\end{itemize}

\texttt{Returns}
\begin{itemize}
  \item \texttt{amax}: \texttt{coo_matrix} or \texttt{scalar}
\end{itemize}
Maximum of \( a \). If \( axis \) is None, the result is a scalar value. If \( axis \) is given, the result is a sparse.coo_matrix of dimension \( a\.ndim - 1 \).

See also:

**min**
The minimum value of a sparse matrix along a given axis.

**np.matrix.max**
NumPy’s implementation of ‘max’ for matrices

\( \text{csr_matrix}\.\text{maximum}(\text{other}) \)
Element-wise maximum between this and another matrix.

\( \text{csr_matrix}\.\text{mean}(axis=None, dtype=None, out=None) \)
Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. \( \text{float64} \) intermediate and return values are used for integer inputs.

**Parameters**

- **axis** : \{-2, -1, 0, 1, None\} optional
  
  Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e. \( axis = \text{None} \)).

- **dtype** : data-type, optional
  
  Type to use in computing the mean. For integer inputs, the default is \( \text{float64} \); for floating point inputs, it is the same as the input dtype.

- **out** : \text{np.matrix}, optional
  
  Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

**Returns**

\( m \) : \text{np.matrix}

See also:

**np.matrix.mean**
NumPy’s implementation of ‘mean’ for matrices

\( \text{csr_matrix}\.\text{min}(axis=None, out=None) \)
Return the minimum of the matrix or maximum along an axis. This takes all elements into account, not just the non-zero ones.

**Parameters**

- **axis** : \{-2, -1, 0, 1, None\} optional
  
  Axis along which the sum is computed. The default is to compute the minimum over all the matrix elements, returning a scalar (i.e. \( axis = \text{None} \)).

- **out** : None, optional
  
  This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns**

\( a\text{\_min} \) : \text{coo\_matrix} or scalar

Minimum of \( a \). If \( axis \) is None, the result is a scalar value. If \( axis \) is given, the result is a sparse.coo_matrix of dimension \( a\.ndim - 1 \).

See also:

**max**
The maximum value of a sparse matrix along a given axis.

**np.matrix.min**
NumPy’s implementation of ‘min’ for matrices

\( \text{csr_matrix}\.\text{minimum}(\text{other}) \)
Element-wise minimum between this and another matrix.

\( \text{csr_matrix}\.\text{multiply}(\text{other}) \)
Point-wise multiplication by another matrix, vector, or scalar.
csr_matrix.nonzero()
nonzero indices
Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1,2,0],[0,0,3],[4,0,5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

csr_matrix.power(n, dtype=None)
This function performs element-wise power.

Parameters
- **n**: n is a scalar
- **dtype**: If dtype is not specified, the current dtype will be preserved.

csr_matrix.prune()
Remove empty space after all non-zero elements.

csr_matrix.rad2deg()
Element-wise rad2deg.
See numpy.rad2deg for more information.

csr_matrix.reshape(shape, order='C')
Gives a new shape to a sparse matrix without changing its data.

Parameters
- **shape**: length-2 tuple of ints
  The new shape should be compatible with the original shape.
- **order**: ‘C’, optional
  This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns
- **reshaped_matrix**: self with the new dimensions of shape

See also:
- `np.matrix.reshape`
  NumPy’s implementation of ‘reshape’ for matrices

csr_matrix.rint()
Element-wise rint.
See numpy.rint for more information.

csr_matrix.set_shape(shape)
See reshape.

csr_matrix.setdiag(values, k=0)
Set diagonal or off-diagonal elements of the array.

Parameters
- **values**: array_like
  New values of the diagonal elements.
  Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values if longer than the diagonal, then the remaining values are ignored.
  If a scalar value is given, all of the diagonal is set to it.
- **k**: int, optional
  Which off-diagonal to set, corresponding to elements a[i,i+k]. Default: 0 (the main diagonal).
csr_matrix.sign()
Element-wise sign.
See numpy.sign for more information.

csr_matrix.sin()
Element-wise sin.
See numpy.sin for more information.

csr_matrix.sinh()
Element-wise sinh.
See numpy.sinh for more information.

csr_matrix.sort_indices()
Sort the indices of this matrix in place

csr_matrix.sorted_indices()
Return a copy of this matrix with sorted indices

csr_matrix.sqrt()
Element-wise sqrt.
See numpy.sqrt for more information.

csr_matrix.sum(axis=None, dtype=None, out=None)
Sum the matrix elements over a given axis.

Parameters
axis : {-2, -1, 0, 1, None} optional
Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e. axis = None).
dtype : dtype, optional
The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of a is used by default unless a has an integer dtype of less precision than the default platform integer. In that case, if a is signed then the platform integer is used while if a is unsigned then an unsigned integer of the same precision as the platform integer is used.
out : np.matrix, optional
Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

Returns
sum_along_axis : np.matrix
A matrix with the same shape as self, with the specified axis removed.

See also:
np.matrix.sum
NumPy’s implementation of ‘sum’ for matrices

csr_matrix.sum_duplicates()
Eliminate duplicate matrix entries by adding them together
The is an in place operation

csr_matrix.tan()
Element-wise tan.
See numpy.tan for more information.

csr_matrix.tanh()
Element-wise tanh.
See numpy.tanh for more information.

```python
csr_matrix.toarray(order=None, out=None)
```
Return a dense ndarray representation of this matrix.

**Parameters**

- `order` : {'C', 'F'}, optional
  Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the `out` argument.

- `out` : ndarray, 2-dimensional, optional
  If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, `out` is required to be memory contiguous (either C or Fortran ordered).

**Returns**

- `arr` : ndarray, 2-dimensional
  An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If `out` was passed, the same object is returned after being modified in-place to contain the appropriate values.

```python
csr_matrix.tobsr(blocksize=None, copy=True)
```
Convert this matrix to Block Sparse Row format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant bsr_matrix.

When `blocksize=(R, C)` is provided, it will be used for construction of the bsr_matrix.

```python
csr_matrix.tocoo(copy=True)
```
Convert this matrix to COOrdinate format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant coo_matrix.

```python
csr_matrix.tocsc(copy=False)
```
Convert this matrix to Compressed Sparse Column format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant csc_matrix.

```python
csr_matrix.tocsr(copy=False)
```
Convert this matrix to Compressed Sparse Row format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant csr_matrix.

```python
csr_matrix.todense(order=None, out=None)
```
Return a dense matrix representation of this matrix.

**Parameters**

- `order` : {'C', 'F'}, optional
  Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the `out` argument.

- `out` : ndarray, 2-dimensional, optional
  If specified, uses this array (or numpy.matrix) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

**Returns**

- `arr` : numpy.matrix, 2-dimensional
  A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order.
order. If `out` was passed and was an array (rather than a `numpy.matrix`), it will be filled with the appropriate values and returned wrapped in a `numpy.matrix` object that shares the same memory.

```python
csr_matrix.todia(copy=False)
Convert this matrix to sparse DIAgonal format.

With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.

csr_matrix.todok(copy=False)
Convert this matrix to Dictionary Of Keys format.

With copy=False, the data/indices may be shared between this matrix and the resultant dok_matrix.

csr_matrix.tolil(copy=False)
Convert this matrix to LInked List format.

With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.

csr_matrix.transpose(axes=None, copy=False)
Reverses the dimensions of the sparse matrix.
```

Parameters
----------

- **axes**: None, optional
  This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value.
- **copy**: bool, optional
  Indicates whether or not attributes of `self` should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns
-------

- **p**: `self` with the dimensions reversed.

See also:
---------

- `np.matrix.transpose`
  NumPy’s implementation of ‘transpose’ for matrices

```python
csr_matrix.trunc()
Element-wise trunc.

See numpy.trunc for more information.
```

class scipy.sparse.dia_matrix(arg1, shape=None, dtype=None, copy=False)
Sparse matrix with DIAgonal storage

This can be instantiated in several ways:

- `dia_matrix(D)` with a dense matrix
- `dia_matrix(S)` with another sparse matrix S (equivalent to S.todia())
- `dia_matrix((M, N), [dtype])`
  to construct an empty matrix with shape (M, N), dtype is optional, defaulting to dtype=’d’.
- `dia_matrix((data, offsets), shape=(M, N))`
  where the `data[k, :]` stores the diagonal entries for diagonal `offsets[k]`
  (See example below)

Notes
-----

Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

Examples

```python
>>> import numpy as np
>>> from scipy.sparse import dia_matrix

>>> dia_matrix((3, 4), dtype=np.int8).toarray()
array([[0, 0, 0, 0],
[0, 0, 0, 0],
[0, 0, 0, 0]], dtype=int8)

>>> data = np.array([[1, 2, 3, 4]]).repeat(3, axis=0)
>>> offsets = np.array([0, -1, 2])
>>> dia_matrix((data, offsets), shape=(4, 4)).toarray()
array([[1, 0, 3, 0],
[1, 2, 0, 4],
[0, 2, 3, 0],
[0, 0, 3, 4]])
```

Methods

```python
arcsin()
Element-wise arcsin.
arcsinh()
Element-wise arcsinh.
arctan()
Element-wise arctan.
arctanh()
Element-wise arctanh.
asformat(format)
Return this matrix in a given sparse format.
asfptype()
Upcast matrix to a floating point format (if necessary).
astype(dtype[, casting, copy])
Cast the matrix elements to a specified type.
cell()
Element-wise cell.
conj()
Element-wise complex conjugation.
conjugate()
Element-wise complex conjugation.
copy()
Returns a copy of this matrix.
count_nonzero()
Number of non-zero entries, equivalent to
deg2rad()
Element-wise deg2rad.
diagonal([k])
Returns the k-th diagonal of the matrix.
```

</tbody>
</table>

```python
dia_matrix.arcsin()
Element-wise arcsin.
See numpy.arcsin for more information.
```
dia_matrix.arcsinh()
Element-wise arcsinh.
See numpy.arcsinh for more information.

dia_matrix.arctan()
Element-wise arctan.
See numpy.arctan for more information.

dia_matrix.arctanh()
Element-wise arctanh.
See numpy.arctanh for more information.

dia_matrix.asformat(format)
Return this matrix in a given sparse format

Parameters
format : {string, None}
* desired_sparse_matrix_format

• None for no format conversion
• “csr” for csr_matrix format
• “csc” for csc_matrix format
• “lil” for lil_matrix format
• “dok” for dok_matrix format and so on

dia_matrix.asfptype()
Upcast matrix to a floating point format (if necessary)

dia_matrix.astype(dtype, casting='unsafe', copy=True)
Cast the matrix elements to a specified type.

Parameters
dtype : string or numpy dtype
Typecode or data-type to which to cast the data.
casting : {'no', 'equiv', 'safe', 'same_kind', 'unsafe'}, optional
Controls what kind of data casting may occur. Defaults to ‘unsafe’
for backwards compatibility. ‘no’ means the data types should not be
cast at all. ‘equiv’ means only byte-order changes are allowed. ‘safe’
means only casts which can preserve values are allowed. ‘same_kind’
means only safe casts or casts within a kind, like float64 to float32,
are allowed. ‘unsafe’ means any data conversions may be done.
copy : bool, optional
If copy is False, the result might share some memory with this ma-
trix. If copy is True, it is guaranteed that the result and this matrix
do not share any memory.

dia_matrix.ceil()
Element-wise ceil.
See numpy.ceil for more information.

dia_matrix.conj()
Element-wise complex conjugation.
If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

dia_matrix.conjugate()
Element-wise complex conjugation.
If the matrix is of non-complex data type, then this method does nothing and the data is not copied.
dia_matrix.copy()
    Returns a copy of this matrix.
    No data/indices will be shared between the returned value and current matrix.

dia_matrix.count_nonzero()
    Number of non-zero entries, equivalent to
    np.count_nonzero(a.toarray())
    Unlike getnnz() and the nnz property, which return the number of stored entries (the length of the data
    attribute), this method counts the actual number of non-zero entries in data.

dia_matrix.deg2rad()
    Element-wise deg2rad.
    See numpy.deg2rad for more information.

dia_matrix.diagonal(k=0)
    Returns the k-th diagonal of the matrix.
    Parameters
      k : int, optional
        Which diagonal to set, corresponding to elements a[i, i+k]. Default: 0 (the main diagonal).
    See also:
    numpy.diagonal
    Equivalent numpy function.

Examples

>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])

dia_matrix.dot(other)
    Ordinary dot product

Examples

>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)

dia_matrix.expm1()
    Element-wise expm1.
    See numpy.expm1 for more information.

dia_matrix.floor()
    Element-wise floor.
    See numpy.floor for more information.
dia_matrix.getH()
Return the Hermitian transpose of this matrix.

See also:

np.matrix.getH
NumPy’s implementation of getH for matrices

dia_matrix.get_shape()
Get shape of a matrix.

dia_matrix.getcol(j)
Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).

dia_matrix.getformat()
Format of a matrix representation as a string.

dia_matrix.getmaxprint()
Maximum number of elements to display when printed.

dia_matrix.getnnz(axis=None)
Number of stored values, including explicit zeros.

Parameters
axis : None, 0, or 1
Select between the number of values across the whole matrix, in each column, or in each row.

See also:

count_nonzero
Number of non-zero entries

dia_matrix.getrow(i)
Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).

dia_matrix.log1p()
Element-wise log1p.

See numpy.log1p for more information.

dia_matrix.maximum(other)
Element-wise maximum between this and another matrix.

dia_matrix.mean(axis=None, dtype=None, out=None)
Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. float64 intermediate and return values are used for integer inputs.

Parameters
axis : {-2, -1, 0, 1, None} optional
Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e. axis = None).

dtype : data-type, optional
Type to use in computing the mean. For integer inputs, the default is float64; for floating point inputs, it is the same as the input dtype.

out : np.matrix, optional
Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

Returns
m : np.matrix

See also:
**np.matrix.mean**
NumPy's implementation of ‘mean’ for matrices

**dia_matrix.minimum**(other)
Element-wise minimum between this and another matrix.

**dia_matrix.multiply**(other)
Point-wise multiplication by another matrix

**dia_matrix.nonzero**
nonzero indices
Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

**Examples**

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

**dia_matrix.power**(n, dtype=None)
This function performs element-wise power.

Parameters
- **n**: n is a scalar
- **dtype**: If dtype is not specified, the current dtype will be preserved.

**dia_matrix.rad2deg**()
Element-wise rad2deg.
See numpy.rad2deg for more information.

**dia_matrix.reshape**(shape, order='C')
Gives a new shape to a sparse matrix without changing its data.

Parameters
- **shape**: length-2 tuple of ints
  The new shape should be compatible with the original shape.
- **order**: 'C', optional
  This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

Returns
- **reshaped_matrix**: self with the new dimensions of shape

See also:

**np.matrix.reshape**
NumPy's implementation of ‘reshape’ for matrices

**dia_matrix.rint**()
Element-wise rint.
See numpy.rint for more information.

**dia_matrix.set_shape**(shape)
See reshape.

**dia_matrix.setdiag**(values, k=0)
Set diagonal or off-diagonal elements of the array.

Parameters
- **values**: array_like
  New values of the diagonal elements.
Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values if longer than the diagonal, then the remaining values are ignored. If a scalar value is given, all of the diagonal is set to it.

\[ k \]: int, optional
Which off-diagonal to set, corresponding to elements \(a[i,i+k]\). Default: 0 (the main diagonal).

\[ \text{dia_matrix}.\text{sign}() \]
Element-wise sign.
See \numpy\text{.sign} for more information.

\[ \text{dia_matrix}.\text{sin}() \]
Element-wise sin.
See \numpy\text{.sin} for more information.

\[ \text{dia_matrix}.\text{sinh}() \]
Element-wise sinh.
See \numpy\text{.sinh} for more information.

\[ \text{dia_matrix}.\text{sqrt}() \]
Element-wise sqrt.
See \numpy\text{.sqrt} for more information.

\[ \text{dia_matrix}.\text{sum}(axis=None, dtype=None, out=None) \]
Sum the matrix elements over a given axis.

**Parameters**
- \(axis\) : {-2, -1, 0, 1, None} optional
  Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e. \(axis = None\)).
- \(dtype\) : dtype, optional
  The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of \(a\) is used by default unless \(a\) has an integer dtype of less precision than the default platform integer. In that case, if \(a\) is signed then the platform integer is used while if \(a\) is unsigned then an unsigned integer of the same precision as the platform integer is used.
- \(out\) : np.matrix, optional
  Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

**Returns**
- \(sum\_along\_axis\) : np.matrix
  A matrix with the same shape as \(self\), with the specified axis removed.

**See also:**
- \numpy\text{.matrix}.\text{sum}
  NumPy’s implementation of ‘sum’ for matrices

\[ \text{dia_matrix}.\text{tan}() \]
Element-wise tan.
See \numpy\text{.tan} for more information.

\[ \text{dia_matrix}.\text{tanh}() \]
Element-wise tanh.
See \numpy\text{.tanh} for more information.
dia_matrix.toarray(order=None, out=None)
Return a dense ndarray representation of this matrix.

Parameters
order : {'C', 'F'}, optional
Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the out argument.

out : ndarray, 2-dimensional, optional
If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, out is required to be memory contiguous (either C or Fortran ordered).

Returns
arr : ndarray, 2-dimensional
An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If out was passed, the same object is returned after being modified in-place to contain the appropriate values.

dia_matrix.tobsr(blocksize=None, copy=False)
Convert this matrix to Block Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant bsr_matrix.

When blocksize=(R, C) is provided, it will be used for construction of the bsr_matrix.

dia_matrix.tocoocopy=False)
Convert this matrix to COOrdinate format.

With copy=False, the data/indices may be shared between this matrix and the resultant coo_matrix.

dia_matrix.tocsc(copy=False)
Convert this matrix to Compressed Sparse Column format.

With copy=False, the data/indices may be shared between this matrix and the resultant csc_matrix.

dia_matrix.tocsr(copy=False)
Convert this matrix to Compressed Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant csr_matrix.

dia_matrix.todense(order=None, out=None)
Return a dense matrix representation of this matrix.

Parameters
order : {'C', 'F'}, optional
Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the out argument.

out : ndarray, 2-dimensional, optional
If specified, uses this array (or numpy.matrix) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

Returns
arr : numpy.matrix, 2-dimensional
A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If out was passed and was an array (rather than a numpy.matrix), it will be filled with the appropriate values and returned wrapped in a numpy.matrix object that shares the same memory.
dia_matrix.todia(copy=False)
Convert this matrix to sparse DIAgonal format.
With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.

dia_matrix.todok(copy=False)
Convert this matrix to Dictionary Of Keys format.
With copy=False, the data/indices may be shared between this matrix and the resultant dok_matrix.

dia_matrix.tolil(copy=False)
Convert this matrix to LInked List format.
With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.

dia_matrix.transpose(axes=None, copy=False)
Reverses the dimensions of the sparse matrix.

Parameters
axes : None, optional
This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value.
copy : bool, optional
Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns
p : self with the dimensions reversed.

See also:
np.matrix.transpose
NumPy's implementation of ‘transpose’ for matrices

dia_matrix.trunc()
Element-wise trunc.

See numpy.trunc for more information.

class scipy.sparse.dok_matrix(arg1, shape=None, dtype=None, copy=False)
Dictionary Of Keys based sparse matrix.

This is an efficient structure for constructing sparse matrices incrementally.
This can be instantiated in several ways:

dok_matrix(D)
with a dense matrix, D
dok_matrix(S) with a sparse matrix, S
dok_matrix((M,N), [dtype])
create the matrix with initial shape (M,N) dtype is optional, defaulting to dtype='d'

Notes
Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.
Allows for efficient O(1) access of individual elements. Duplicates are not allowed. Can be efficiently converted to a coo_matrix once constructed.

Examples

```python
>>> import numpy as np
>>> from scipy.sparse import dok_matrix
```
>>> S = dok_matrix((5, 5), dtype=np.float32)
>>> for i in range(5):
...     for j in range(5):
...         S[i, j] = i + j  # Update element

dok_matrix.asformat(format)

Return this matrix in a given sparse format

Parameters

format : {string, None}

desired sparse matrix format

- None for no format conversion
- “csr” for csr_matrix format
- “csc” for csc_matrix format
- “lil” for lil_matrix format
- “dok” for dok_matrix format and so on

dok_matrix.asfptype()

Upcast matrix to a floating point format (if necessary)

dok_matrix.astype(dtype, casting=’unsafe’, copy=True)

Cast the matrix elements to a specified type.
Parameters
dtype : string or numpy dtype
   Typecode or data-type to which to cast the data.
casting : {'no', 'equiv', 'safe', 'same_kind', 'unsafe'}, optional
   Controls what kind of data casting may occur. Defaults to ‘unsafe’
   for backwards compatibility. ‘no’ means the data types should not be
   cast at all. ‘equiv’ means only byte-order changes are allowed. ‘safe’
   means only casts which can preserve values are allowed. ‘same_kind’
   means only safe casts or casts within a kind, like float64 to float32,
   are allowed. ‘unsafe’ means any data conversions may be done.
copy : bool, optional
   If copy is False, the result might share some memory with this ma-
   trix. If copy is True, it is guaranteed that the result and this matrix
   do not share any memory.

.. function:: dok_matrix.clear()
   
   .. code:: python

   :return: None.
   
   Remove all items from D.

.. function:: dok_matrix.conj()
   
   .. code:: python

   :return: None.
   
   Element-wise complex conjugation.
   
   If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

.. function:: dok_matrix.conjtransp()
   
   .. code:: python

   :return: None.
   
   Return the conjugate transpose.

.. function:: dok_matrix.conjugate()
   
   .. code:: python

   :return: None.
   
   Element-wise complex conjugation.
   
   If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

.. function:: dok_matrix.copy()
   
   .. code:: python

   :return: None.
   
   Returns a copy of this matrix.
   
   No data/indices will be shared between the returned value and current matrix.

.. function:: dok_matrix.count_nonzero()
   
   .. code:: python

   :return: None.
   
   Number of non-zero entries, equivalent to
   
   np.count_nonzero(a.toarray())
   
   Unlike getnnz() and the nnz property, which return the number of stored entries (the length of the data
   attribute), this method counts the actual number of non-zero entries in data.

.. function:: dok_matrix.diagonal(k=0)
   
   .. code:: python

   :return: None.
   
   Returns the k-th diagonal of the matrix.

   Parameters

   k : int, optional
      Which diagonal to set, corresponding to elements a[i, i+k]. Default:
      0 (the main diagonal).

See also:

numpy.diagonal

Equivalent numpy function.

Examples

>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
```python
>>> A.diagonal(k=1)
array([2, 3])
```

dok_matrix.dot(other)

Ordinary dot product

**Examples**

```python
>>> import numpy as np
>>> from scipy.sparse import csr_matrix

>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1]
```

dok_matrix.fromkeys(S[,v]) → New dict with keys from S and values equal to v.

v defaults to None.

dok_matrix.get(key, default=0.0)

This overrides the dict.get method, providing type checking but otherwise equivalent functionality.

dok_matrix.getH()

Return the Hermitian transpose of this matrix.

See also:

np.matrix.getH

NumPy’s implementation of getH for matrices

dok_matrix.get_shape()

Get shape of a matrix.

dok_matrix.getcol(j)

Returns the j-th column as a (m x 1) DOK matrix.

dok_matrix.getformat()

Format of a matrix representation as a string.

dok_matrix.getmaxprint()

Maximum number of elements to display when printed.

dok_matrix.getnnz(axis=None)

Number of stored values, including explicit zeros.

Parameters

axis : None, 0, or 1

Select between the number of values across the whole matrix, in each column, or in each row.

See also:

count_nonzero

Number of non-zero entries

dok_matrix.getrow(i)

Returns the i-th row as a (1 x n) DOK matrix.

dok_matrix.has_key(k) → True if D has a key k, else False

dok_matrix.items() → list of D’s (key, value) pairs, as 2-tuples
dok_matrix.iteratoritems() → an iterator over the (key, value) items of D

dok_matrix.iterkeys() → an iterator over the keys of D

dok_matrix.itervalues() → an iterator over the values of D

dok_matrix.keys() → list of D’s keys

dok_matrix.maximum(other)  
Element-wise maximum between this and another matrix.

dok_matrix.mean(axis=None, dtype=None, out=None)  
Compute the arithmetic mean along the specified axis.  
Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. float64 intermediate and return values are used for integer inputs.

   Parameters
   axis : {-2, -1, 0, 1, None} optional  
      Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e. axis = None).

dtype : data-type, optional  
      Type to use in computing the mean. For integer inputs, the default is float64; for floating point inputs, it is the same as the input dtype.

out : np.matrix, optional  
      Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

   Returns
   m : np.matrix

See also:

np.matrix.mean  
NumPy’s implementation of ‘mean’ for matrices

dok_matrix.minimum(other)  
Element-wise minimum between this and another matrix.

dok_matrix.multiply(other)  
Point-wise multiplication by another matrix

dok_matrix.nonzero()  
nonzero indices

Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

Examples

```python
>>> from scipy.sparse import csr_matrix  
>>> A = csr_matrix(([1,2,0],[0,0,3],[4,0,5]))  
>>> A.nonzero()  
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

dok_matrix.pop(k[, d]) → v, remove specified key and return the corresponding value. 
If key is not found, d is returned if given, otherwise KeyError is raised

dok_matrix.popitem() → (k, v), remove and return some (key, value) pair as a 2-tuple; but raise KeyError if D is empty.
dok_matrix.power(n, dtype=None)
Element-wise power.

dok_matrix.reshape(shape, order='C')
Gives a new shape to a sparse matrix without changing its data.

Parameters
  - shape : length-2 tuple of ints
    The new shape should be compatible with the original shape.
  - order : ‘C’, optional
    This argument is in the signature solely for NumPy compatibility rea-
    sons. Do not pass in anything except for the default value, as this
    argument is not used.

Returns
  reshaped_matrix : self with the new dimensions of shape

See also:
np.matrix.reshape
NumPy’s implementation of ‘reshape’ for matrices

dok_matrix.resize(shape)
Resize the matrix in-place to dimensions given by shape.
Any non-zero elements that lie outside the new shape are removed.

dok_matrix.set_shape(shape)
See reshape.

dok_matrix.setdefault(k[, d]) → D.get(k,d), also set D[k]=d if k not in D

dok_matrix.setdiag(values, k=0)
Set diagonal or off-diagonal elements of the array.

Parameters
  - values : array_like
    New values of the diagonal elements.
    Values may have any length. If the diagonal is longer than values,
    then the remaining diagonal entries will not be set. If values if longer
    than the diagonal, then the remaining values are ignored.
    If a scalar value is given, all of the diagonal is set to it.
  - k : int, optional
    Which off-diagonal to set, corresponding to elements a[i,i+k]. De-
    fault: 0 (the main diagonal).

dok_matrix.sum(axis=None, dtype=None, out=None)
Sum the matrix elements over a given axis.

Parameters
  - axis : {-2,-1, 0, 1, None} optional
    Axis along which the sum is computed. The default is to compute the
    sum of all the matrix elements, returning a scalar (i.e. axis = None).
  - dtype : dtype, optional
    The type of the returned matrix and of the accumulator in which the
    elements are summed. The dtype of a is used by default unless a has
    an integer dtype of less precision than the default platform integer.
    In that case, if a is signed then the platform integer is used while if
    a is unsigned then an unsigned integer of the same precision as the
    platform integer is used.
  - out : np.matrix, optional
    Alternative output matrix in which to place the result. It must have
    the same shape as the expected output, but the type of the output
    values will be cast if necessary.

Returns
  sum_along_axis : np.matrix
A matrix with the same shape as `self`, with the specified axis removed.

**See also:**

- `np.matrix.sum`
  - NumPy’s implementation of ‘sum’ for matrices
- `dok_matrix.toarray(order=None, out=None)`
  - Return a dense ndarray representation of this matrix.

**Parameters**

- `order`: {'C', 'F'}, optional
  - Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the `out` argument.
- `out`: ndarray, 2-dimensional, optional
  - If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, `out` is required to be memory contiguous (either C or Fortran ordered).

**Returns**

- `arr`: ndarray, 2-dimensional
  - An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If `out` was passed, the same object is returned after being modified in-place to contain the appropriate values.

- `dok_matrix.tobsr(blocksize=None, copy=False)`
  - Convert this matrix to Block Sparse Row format.

  With `copy=False`, the data/indices may be shared between this matrix and the resultant bsr_matrix.

  When `blocksize=(R, C)` is provided, it will be used for construction of the bsr_matrix.

- `dok_matrix.tocoo(copy=False)`
  - Convert this matrix to COOrdinate format.

  With `copy=False`, the data/indices may be shared between this matrix and the resultant coo_matrix.

- `dok_matrix.tocsc(copy=False)`
  - Convert this matrix to Compressed Sparse Column format.

  With `copy=False`, the data/indices may be shared between this matrix and the resultant csc_matrix.

- `dok_matrix.tocsr(copy=False)`
  - Convert this matrix to Compressed Sparse Row format.

  With `copy=False`, the data/indices may be shared between this matrix and the resultant csr_matrix.

- `dok_matrix.todense(order=None, out=None)`
  - Return a dense matrix representation of this matrix.

**Parameters**

- `order`: {'C', 'F'}, optional
  - Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the `out` argument.
- `out`: ndarray, 2-dimensional, optional
  - If specified, uses this array (or `numpy.matrix`) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.
Returns

arr : numpy.matrix, 2-dimensional
A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If out was passed and was an array (rather than a numpy.matrix), it will be filled with the appropriate values and returned wrapped in a numpy.matrix object that shares the same memory.

dok_matrix.todia(copy=False)
Convert this matrix to sparse DIAgonal format.
With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.

dok_matrix.todok(copy=False)
Convert this matrix to Dictionary Of Keys format.
With copy=False, the data/indices may be shared between this matrix and the resultant dok_matrix.

dok_matrix.tolil(copy=False)
Convert this matrix to LInked List format.
With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.

dok_matrix.transpose(axes=None, copy=False)
Reverses the dimensions of the sparse matrix.

Parameters

axes : None, optional
This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value.

copy : bool, optional
Indicates whether or not attributes of self should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

Returns

p : self with the dimensions reversed.

See also:

np.matrix.transpose
NumPy’s implementation of ‘transpose’ for matrices

dok_matrix.update(val)

dok_matrix.values() → list of D’s values

dok_matrix.viewitems() → a set-like object providing a view on D’s items

dok_matrix.viewkeys() → a set-like object providing a view on D’s keys

dok_matrix.viewvalues() → an object providing a view on D’s values

class scipy.sparse.lil_matrix(arg1, shape=None, dtype=None, copy=False)
Row-based linked list sparse matrix
This is a structure for constructing sparse matrices incrementally. Note that inserting a single item can take linear time in the worst case; to construct a matrix efficiently, make sure the items are pre-sorted by index, per row.
This can be instantiated in several ways:

lil_matrix(D) with a dense matrix or rank-2 ndarray D
lil_matrix(S)  with another sparse matrix S (equivalent to S.tolil())
lil_matrix((M, N), [dtype])
to construct an empty matrix with shape (M, N) dtype is optional, defaulting to dtype='d'.

Notes
Sparse matrices can be used in arithmetic operations: they support addition, subtraction, multiplication, division, and matrix power.

Advantages of the LIL format

• supports flexible slicing
• changes to the matrix sparsity structure are efficient

Disadvantages of the LIL format

• arithmetic operations LIL + LIL are slow (consider CSR or CSC)
• slow column slicing (consider CSC)
• slow matrix vector products (consider CSR or CSC)

Intended Usage

• LIL is a convenient format for constructing sparse matrices
• once a matrix has been constructed, convert to CSR or CSC format for fast arithmetic and matrix vector operations
• consider using the COO format when constructing large matrices

Data Structure

• An array (self.rows) of rows, each of which is a sorted list of column indices of non-zero elements.
• The corresponding nonzero values are stored in similar fashion in self.data.

### lil_matrix.asformat(format)

Return this matrix in a given sparse format

**Parameters**

- **format**: {string, None}  
  
  **desired sparse matrix format**

- None for no format conversion  
- “csr” for csr_matrix format  
- “csc” for csc_matrix format  
- “lil” for lil_matrix format  
- “dok” for dok_matrix format and so on
lil_matrix.\texttt{asfptype}()
Upcast matrix to a floating point format (if necessary)

lil_matrix.\texttt{astype}(\texttt{dtype}, \texttt{casting}=\texttt{\textquotesingle unsafe\textquotesingle}, \texttt{copy=\texttt{True}})
Cast the matrix elements to a specified type.

\textbf{Parameters}
\begin{itemize}
\item \texttt{dtype} : string or numpy dtype 
Typecode or data-type to which to cast the data.
\item \texttt{casting} : \{'no', \texttt{\textquotesingle equiv\textquotesingle}, \texttt{\textquotesingle safe\textquotesingle}, \texttt{\textquotesingle same\_kind\textquotesingle}, \texttt{\textquotesingle unsafe\textquotesingle}\}, optional
Controls what kind of data casting may occur. Defaults to \texttt{\textquotesingle unsafe\textquotesingle} for backwards compatibility. \texttt{\textquotesingle no\textquotesingle} means the data types should not be cast at all. \texttt{\textquotesingle equiv\textquotesingle} means only byte-order changes are allowed. \texttt{\textquotesingle safe\textquotesingle} means only casts which can preserve values are allowed. \texttt{\textquotesingle same\_kind\textquotesingle} means only safe casts or casts within a kind, like \texttt{float64} to \texttt{float32}, are allowed. \texttt{\textquotesingle unsafe\textquotesingle} means any data conversions may be done.
\item \texttt{copy} : boolean, optional
If \texttt{copy} is \texttt{\textquotesingle False\textquotesingle}, the result might share some memory with this matrix. If \texttt{copy} is \texttt{\textquotesingle True\textquotesingle}, it is guaranteed that the result and this matrix do not share any memory.
\end{itemize}

lil_matrix.\texttt{conj}()
Element-wise complex conjugation.

If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

lil_matrix.\texttt{conjugate}()
Element-wise complex conjugation.

If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

lil_matrix.\texttt{copy}()
Returns a copy of this matrix.

No data/indices will be shared between the returned value and current matrix.

lil_matrix.\texttt{count\_nonzero}()
Number of non-zero entries, equivalent to
\begin{verbatim}
np.count_nonzero(a.toarray())
\end{verbatim}
Unlike \texttt{getnnz()} and the \texttt{nnz} property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

lil_matrix.\texttt{diagonal}(k=0)
Returns the k-th diagonal of the matrix.

\textbf{Parameters}
\begin{itemize}
\item \texttt{k} : int, optional
Which diagonal to set, corresponding to elements \[a[i, i+k]\]. Default: 0 (the main diagonal).
\end{itemize}

\textbf{See also:}
\begin{itemize}
\item \texttt{numpy.diagonal}
Equivalent numpy function.
\end{itemize}

\textbf{Examples}
\begin{verbatim}
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
\end{verbatim}
lil_matrix.dot(other)
Ordinary dot product

Examples

```python
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

lil_matrix.getH()
Return the Hermitian transpose of this matrix.

See also:

np.matrix.getH
NumPy’s implementation of getH for matrices

lil_matrix.get_shape()
Get shape of a matrix.

lil_matrix.getcol(j)
Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).

lil_matrix.getformat()
Format of a matrix representation as a string.

lil_matrix.getmaxprint()
Maximum number of elements to display when printed.

lil_matrix.getnnz(axis=None)
Number of stored values, including explicit zeros.

Parameters

axis : None, 0, or 1
Select between the number of values across the whole matrix, in each column, or in each row.

See also:

count_nonzero
Number of non-zero entries

lil_matrix.getrow(i)
Returns a copy of the ‘i’th row.

lil_matrix.getrowview(i)
Returns a view of the ‘i’th row (without copying).

lil_matrix.maximum(other)
Element-wise maximum between this and another matrix.

lil_matrix.mean(axis=None, dtype=None, out=None)
Compute the arithmetic mean along the specified axis.

Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. float64 intermediate and return values are used for integer inputs.
**Parameters**

- **axis**: \{-2, -1, 0, 1, None\} optional
  - Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e. `axis = None`).
- **dtype**: data-type, optional
  - Type to use in computing the mean. For integer inputs, the default is `float64`; for floating point inputs, it is the same as the input dtype.
- **out**: np.matrix, optional
  - Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

**Returns**

- **m**: np.matrix

See also:

- **np.matrix.mean**
  - NumPy’s implementation of ‘mean’ for matrices
- **lil_matrix.minimum**(other)
  - Element-wise minimum between this and another matrix.
- **lil_matrix.multiply**(other)
  - Point-wise multiplication by another matrix
- **lil_matrix.nonzero()**
  - nonzero indices
  - Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.

**Examples**

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1,2,0],[0,0,3],[4,0,5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

- **lil_matrix.power**(n, dtype=None)
  - Element-wise power.
- **lil_matrix.reshape**(shape, order='C')
  - Gives a new shape to a sparse matrix without changing its data.

**Parameters**

- **shape**: length-2 tuple of ints
  - The new shape should be compatible with the original shape.
- **order**: ‘C’, optional
  - This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

**Returns**

- **reshaped_matrix**: self with the new dimensions of `shape`

See also:

- **np.matrix.reshape**
  - NumPy’s implementation of ‘reshape’ for matrices
- **lil_matrix.set_shape**(shape)
  - See `reshape`.
- **lil_matrix.setdiag**(values, k=0)
  - Set diagonal or off-diagonal elements of the array.

**Parameters**

- **values**: array_like
New values of the diagonal elements. Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values if longer than the diagonal, then the remaining values are ignored. If a scalar value is given, all of the diagonal is set to it.

\[ k \]: int, optional
Which off-diagonal to set, corresponding to elements \( a[i,i+k] \). Default: 0 (the main diagonal).

\texttt{lil\_matrix.sum}(axis=None, dtype=None, out=None)
Sum the matrix elements over a given axis.

**Parameters**
- \texttt{axis}: \{-2, -1, 0, 1, None\} optional
  Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e. \texttt{axis = None}).
- \texttt{dtype}: dtype, optional
  The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of \( a \) is used by default unless \( a \) has an integer dtype of less precision than the default platform integer. In that case, if \( a \) is signed then the platform integer is used while if \( a \) is unsigned then an unsigned integer of the same precision as the platform integer is used.
- \texttt{out}: np.matrix, optional
  Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

**Returns**
- \texttt{sum\_along\_axis}: np.matrix
  A matrix with the same shape as \texttt{self}, with the specified axis removed.

See also:
\texttt{np.matrix.sum}
NumPy's implementation of 'sum' for matrices

\texttt{lil\_matrix.toarray}(order=None, out=None)
Return a dense ndarray representation of this matrix.

**Parameters**
- \texttt{order}: \{'C', 'F'\}, optional
  Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is 'None', indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the \texttt{out} argument.
- \texttt{out}: ndarray, 2-dimensional, optional
  If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, \texttt{out} is required to be memory contiguous (either C or Fortran ordered).

**Returns**
- \texttt{arr}: ndarray, 2-dimensional
  An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If \texttt{out} was passed, the same object is returned after being modified in-place to contain the appropriate values.

\texttt{lil\_matrix.tobsr}(blocksize=None, copy=False)
Convert this matrix to Block Sparse Row format.

With \texttt{copy=False}, the data/indices may be shared between this matrix and the resultant \texttt{bsr\_matrix}.
When blocksize=(R, C) is provided, it will be used for construction of the bsr_matrix.

```
lil_matrix.tocoo(copy=False)
```
Convert this matrix to COOrdinate format.

With copy=False, the data/indices may be shared between this matrix and the resultant coo_matrix.

```
lil_matrix.tocsc(copy=False)
```
Convert this matrix to Compressed Sparse Column format.

With copy=False, the data/indices may be shared between this matrix and the resultant csc_matrix.

```
lil_matrix.tocsr(copy=False)
```
Convert this matrix to Compressed Sparse Row format.

With copy=False, the data/indices may be shared between this matrix and the resultant csr_matrix.

```
lil_matrix.todense(order=None, out=None)
```
Return a dense matrix representation of this matrix.

**Parameters**

- `order`: {'C', 'F'}, optional
  Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the `out` argument.

- `out`: ndarray, 2-dimensional, optional
  If specified, uses this array (or `numpy.matrix`) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.

**Returns**

- `arr`: `numpy.matrix`, 2-dimensional
  A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If `out` was passed and was an array (rather than a `numpy.matrix`), it will be filled with the appropriate values and returned wrapped in a `numpy.matrix` object that shares the same memory.

```
lil_matrix.todia(copy=False)
```
Convert this matrix to sparse DIAgonal format.

With copy=False, the data/indices may be shared between this matrix and the resultant dia_matrix.

```
lil_matrix.todok(copy=False)
```
Convert this matrix to Dictionary Of Keys format.

With copy=False, the data/indices may be shared between this matrix and the resultant dok_matrix.

```
lil_matrix.tolil(copy=False)
```
Convert this matrix to LInked List format.

With copy=False, the data/indices may be shared between this matrix and the resultant lil_matrix.

```
lil_matrix.transpose(axes=None, copy=False)
```
Reverses the dimensions of the sparse matrix.

**Parameters**

- `axes`: None, optional
  This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value.

- `copy`: bool, optional
  Indicates whether or not attributes of `self` should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

**Returns**

- `p`: `self` with the dimensions reversed.
See also:

`np.matrix.transpose`
NumPy's implementation of ‘transpose’ for matrices

class `scipy.sparse.spmatrix` *(maxprint=50)*
This class provides a base class for all sparse matrices. It cannot be instantiated. Most of the work is provided by subclasses.

**spmatrix.asformat** *(format)*

Return this matrix in a given sparse format

*Parameters*

- **format**: {string, None}

  *desired sparse matrix format*

  - None for no format conversion
  - “csr” for csr_matrix format
  - “csc” for csc_matrix format
  - “lil” for lil_matrix format
  - “dok” for dok_matrix format and so on

**spmatrix.asfptype()**

Upcast matrix to a floating point format (if necessary)

**spmatrix.astype**(dtype, casting=’unsafe’, copy=True)

Cast the matrix elements to a specified type.

*Parameters*

- **dtype**: string or numpy dtype

  Typecode or data-type to which to cast the data.

- **casting**: {“no”, “equiv”, “safe”, “same_kind”, “unsafe”}, optional

  Controls what kind of data casting may occur. Defaults to ‘unsafe’ for backwards compatibility. ‘no’ means the data types should not be cast at all. ‘equiv’ means only byte-order changes are allowed. ‘safe’ means only casts which can preserve values are allowed. ‘same_kind’ means only safe casts or casts within a kind, like float64 to float32, are allowed. ‘unsafe’ means any data conversions may be done.

- **copy**: bool, optional

  If copy is False, the result might share some memory with this matrix. If copy is True, it is guaranteed that the result and this matrix do not share any memory.

**spmatrix.conj()**

Element-wise complex conjugation.

If the matrix is of non-complex data type, then this method does nothing and the data is not copied.
spmatrix.conjugate()
Element-wise complex conjugation.
If the matrix is of non-complex data type, then this method does nothing and the data is not copied.

spmatrix.copy()
Returns a copy of this matrix.
No data/indices will be shared between the returned value and current matrix.

spmatrix.count_nonzero()
Number of non-zero entries, equivalent to
np.count_nonzero(a.toarray())
Unlike getnnz() and the nnz property, which return the number of stored entries (the length of the data
attribute), this method counts the actual number of non-zero entries in data.

spmatrix.diagonal(k=0)
Returns the k-th diagonal of the matrix.
Parameters
k : int, optional
Which diagonal to set, corresponding to elements a[i, i+k]. Default: 0 (the main diagonal).
See also:
numpy.diagonal
Equivalent numpy function.

Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> A.diagonal()
array([1, 0, 5])
>>> A.diagonal(k=1)
array([2, 3])
```

spmatrix.dot(other)
Ordinary dot product

Examples

```python
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
>>> A.dot(v)
array([ 1, -3, -1], dtype=int64)
```

spmatrix.getH()
Return the Hermitian transpose of this matrix.
See also:

np.matrix.getH
NumPy's implementation of getH for matrices

spmatrix.get_shape()
Get shape of a matrix.
spmatrix.getcol(j)
Returns a copy of column j of the matrix, as an (m x 1) sparse matrix (column vector).

spmatrix.getformat()
Format of a matrix representation as a string.

spmatrix.getmaxprint()
Maximum number of elements to display when printed.

spmatrix.getnnz(axis=None)
Number of stored values, including explicit zeros.

Parameters
axis : None, 0, or 1
Select between the number of values across the whole matrix, in each column, or in each row.

See also:
count_nonzero
Number of non-zero entries

spmatrix.getrow(i)
Returns a copy of row i of the matrix, as a (1 x n) sparse matrix (row vector).

spmatrix.maximum(other)
Element-wise maximum between this and another matrix.

spmatrix.mean(axis=None, dtype=None, out=None)
Compute the arithmetic mean along the specified axis.
Returns the average of the matrix elements. The average is taken over all elements in the matrix by default, otherwise over the specified axis. float64 intermediate and return values are used for integer inputs.

Parameters
axis : {-2, -1, 0, 1, None} optional
Axis along which the mean is computed. The default is to compute the mean of all elements in the matrix (i.e. axis = None).

dtype : data-type, optional
Type to use in computing the mean. For integer inputs, the default is float64; for floating point inputs, it is the same as the input dtype.

out : np.matrix, optional
Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

Returns
m : np.matrix

See also:
np.matrix.mean
NumPy’s implementation of ‘mean’ for matrices

spmatrix.minimum(other)
Element-wise minimum between this and another matrix.

spmatrix.multiply(other)
Point-wise multiplication by another matrix

spmatrix.nonzero()
nonzero indices
Returns a tuple of arrays (row,col) containing the indices of the non-zero elements of the matrix.
Examples

```python
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1,2,0],[0,0,3],[4,0,5]])
>>> A.nonzero()
(array([0, 0, 1, 2, 2]), array([0, 1, 2, 0, 2]))
```

- `spmatrix.power(n, dtype=None)`
  Element-wise power.

- `spmatrix.reshape(shape, order='C')`
  Gives a new shape to a sparse matrix without changing its data.

  **Parameters**
  - `shape`: length-2 tuple of ints
    The new shape should be compatible with the original shape.
  - `order`: ‘C’, optional
    This argument is in the signature *solely* for NumPy compatibility reasons. Do not pass in anything except for the default value, as this argument is not used.

  **Returns**
  - `reshaped_matrix`: `self` with the new dimensions of `shape`

  **See also:**
  - `np.matrix.reshape`
    NumPy's implementation of `reshape` for matrices

- `spmatrix.set_shape(shape)`
  See `reshape`.

- `spmatrix.setdiag(values, k=0)`
  Set diagonal or off-diagonal elements of the array.

  **Parameters**
  - `values`: array_like
    New values of the diagonal elements.
    Values may have any length. If the diagonal is longer than values, then the remaining diagonal entries will not be set. If values if longer than the diagonal, then the remaining values are ignored.
    If a scalar value is given, all of the diagonal is set to it.
  - `k`: int, optional
    Which off-diagonal to set, corresponding to elements `a[i,i+k]`. Default: 0 (the main diagonal).

- `spmatrix.sum(axis=None, dtype=None, out=None)`
  Sum the matrix elements over a given axis.

  **Parameters**
  - `axis`: {-2, -1, 0, 1, None} optional
    Axis along which the sum is computed. The default is to compute the sum of all the matrix elements, returning a scalar (i.e. `axis = None`).
  - `dtype`: dtype, optional
    The type of the returned matrix and of the accumulator in which the elements are summed. The dtype of `a` is used by default unless `a` has an integer dtype of less precision than the default platform integer. In that case, if `a` is signed then the platform integer is used while if `a` is unsigned then an unsigned integer of the same precision as the platform integer is used.
  - `out`: np.matrix, optional
    Alternative output matrix in which to place the result. It must have the same shape as the expected output, but the type of the output values will be cast if necessary.

  **Returns**
  - `sum_along_axis`: np.matrix
A matrix with the same shape as `self`, with the specified axis removed.

See also:

`np.matrix.sum`
NumPy’s implementation of ‘sum’ for matrices

`spmatrix.toarray(order=None, out=None)`
Return a dense ndarray representation of this matrix.

**Parameters**

- `order`: {‘C’, ‘F’}, optional
  Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the `out` argument.

- `out`: ndarray, 2-dimensional, optional
  If specified, uses this array as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method. For most sparse types, `out` is required to be memory contiguous (either C or Fortran ordered).

**Returns**

- `arr`: ndarray, 2-dimensional
  An array with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If `out` was passed, the same object is returned after being modified in-place to contain the appropriate values.

`spmatrix.tobsr(blocksize=None, copy=False)`
Convert this matrix to Block Sparse Row format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant bsr_matrix.

When `blocksize=(R, C)` is provided, it will be used for construction of the bsr_matrix.

`spmatrix.tocoo(copy=False)`
Convert this matrix to COOrdinate format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant coo_matrix.

`spmatrix.tocsc(copy=False)`
Convert this matrix to Compressed Sparse Column format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant csc_matrix.

`spmatrix.tocsr(copy=False)`
Convert this matrix to Compressed Sparse Row format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant csr_matrix.

`spmatrix.todense(order=None, out=None)`
Return a dense matrix representation of this matrix.

**Parameters**

- `order`: {‘C’, ‘F’}, optional
  Whether to store multi-dimensional data in C (row-major) or Fortran (column-major) order in memory. The default is ‘None’, indicating the NumPy default of C-ordered. Cannot be specified in conjunction with the `out` argument.

- `out`: ndarray, 2-dimensional, optional
  If specified, uses this array (or `numpy.matrix`) as the output buffer instead of allocating a new array to return. The provided array must have the same shape and dtype as the sparse matrix on which you are calling the method.
**Returns**

`arr` : `numpy.matrix`, 2-dimensional

A NumPy matrix object with the same shape and containing the same data represented by the sparse matrix, with the requested memory order. If `out` was passed and was an array (rather than a `numpy.matrix`), it will be filled with the appropriate values and returned wrapped in a `numpy.matrix` object that shares the same memory.

```python
spmatrix.todia(copy=False)
```

Convert this matrix to sparse DIAgonal format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `dia_matrix`.

```python
spmatrix.todok(copy=False)
```

Convert this matrix to Dictionary Of Keys format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `dok_matrix`.

```python
spmatrix.tolil(copy=False)
```

Convert this matrix to LIked List format.

With `copy=False`, the data/indices may be shared between this matrix and the resultant `lil_matrix`.

```python
spmatrix.transpose(axes=None, copy=False)
```

Reverses the dimensions of the sparse matrix.

**Parameters**

- `axes` : None, optional
  - This argument is in the signature solely for NumPy compatibility reasons. Do not pass in anything except for the default value.

- `copy` : bool, optional
  - Indicates whether or not attributes of `self` should be copied whenever possible. The degree to which attributes are copied varies depending on the type of sparse matrix being used.

**Returns**

`p` : `self` with the dimensions reversed.

**scipy.sparse.eye**

(m, n=None, k=0, dtype='float', format=None)

Sparse matrix with ones on diagonal

Returns a sparse (m x n) matrix where the k-th diagonal is all ones and everything else is zeros.

**Parameters**

- **m**: int
  - Number of rows in the matrix.
- **n**: int, optional
  - Number of columns. Default: m.
- **k**: int, optional
  - Diagonal to place ones on. Default: 0 (main diagonal).
- **dtype**: dtype, optional
  - Data type of the matrix.
- **format**: str, optional
  - Sparse format of the result, e.g. format="csr", etc.

**Examples**

```python
>>> from scipy import sparse
>>> sparse.eye(3).toarray()
array([[ 1., 0., 0.],
       [ 0., 1., 0.],
       [ 0., 0., 1.]])
```

**scipy.sparse.identity**

(n, dtype='d', format=None)

Identity matrix in sparse format

Returns an identity matrix with shape (n,n) using a given sparse format and dtype.

**Parameters**

- **n**: int
  - Shape of the identity matrix.
- **dtype**: dtype, optional
  - Data type of the matrix.
- **format**: str, optional
  - Sparse format of the result, e.g. format="csr", etc.

**Examples**

```python
>>> from scipy.sparse import identity
>>> identity(3).toarray()
array([[ 1., 0., 0.],
       [ 0., 1., 0.],
       [ 0., 0., 1.]])
```
scipy.sparse.kron(A, B, format=None)
kron product of sparse matrices A and B

**Parameters**
- A : sparse or dense matrix
  - first matrix of the product
- B : sparse or dense matrix
  - second matrix of the product
- format : str, optional
  - format of the result (e.g. “csr”)

**Returns**
- kronecker product in a sparse matrix format

**Examples**
```python
>>> from scipy import sparse
>>> A = sparse.csr_matrix(np.array([[0, 2], [5, 0]]))
>>> B = sparse.csr_matrix(np.array([[1, 2], [3, 4]]))
>>> sparse.kron(A, B).toarray()
array([[ 0,  0,  2,  4],
       [ 0,  0,  6,  8],
       [ 5, 10,  0,  0],
       [15, 20,  0,  0]])
```

scipy.sparse.kronsum(A, B, format=None)
kron sum of sparse matrices A and B

Kronecker sum of two sparse matrices is a sum of two Kronecker products kron(I_n,A) + kron(B,I_m) where A has shape (m,m) and B has shape (n,n) and I_m and I_n are identity matrices of shape (m,m) and (n,n) respectively.

**Parameters**
- A : square matrix
- B : square matrix
- format : str
  - format of the result (e.g. “csr”)

**Returns**
- kronecker sum in a sparse matrix format

scipy.sparse.diags(diagonals, offsets=0, shape=None, format=None, dtype=None)
Construct a sparse matrix from diagonals.

**Parameters**
- diagonals : sequence of array_like
  - Sequence of arrays containing the matrix diagonals, corresponding to offsets.
- offsets : sequence of int or an int, optional
- shape : tuple of int, optional

**Diagonals to set:**
- k = 0 the main diagonal (default)
- k > 0 the k-th upper diagonal
- k < 0 the k-th lower diagonal

Shape of the result. If omitted, a square matrix large enough to contain the diagonals is returned.
format : {"dia", "csr", "csc", "lil", ...}, optional
Matrix format of the result. By default (format=None) an appropriate sparse
matrix format is returned. This choice is subject to change.

dtype : dtype, optional
Data type of the matrix.

See also:
spdia ns construct matrix from diagonals

Notes
This function differs from spdiags in the way it handles off-diagonals.
The result from diags is the sparse equivalent of:

```python
def spdiags(data, diags, m, n, format=None):
    return CooMatrix(
        np.diag(diagonals[0], offsets[0])
        + ...
        + np.diag(diagonals[k], offsets[k])
    )
```

Repeated diagonal offsets are disallowed.
New in version 0.11.

Examples

```python
>>> from scipy.sparse import diags
>>> diagonals = [[1, 2, 3, 4], [1, 2, 3], [1, 2]]
>>> diags(diagonals, [0, -1, 2]).toarray()
array([[1, 0, 1, 0],
       [1, 2, 0, 2],
       [0, 2, 3, 0],
       [0, 0, 3, 4]])
```

Broadcasting of scalars is supported (but shape needs to be specified):

```python
>>> diags([-1, -2, 1], [-1, 0, 1], shape=(4, 4)).toarray()
array([[-2., 1., 0., 0.],
       [ 1., -2., 1., 0.],
       [ 0., 1., -2., 1.],
       [ 0., 0., 1., -2.]])
```

If only one diagonal is wanted (as in numpy.diag), the following works as well:

```python
>>> diags([1, 2, 3], 1).toarray()
array([[0., 1., 0., 0.],
       [0., 0., 2., 0.],
       [0., 0., 0., 3.],
       [0., 0., 0., 0.]])
```

scipy.sparse.spdiags(data, diags, m, n, format=None) Return a sparse matrix from diagonals.

Parameters data : array_like
    matrix diagonals stored row-wise

diags : diagonals to set
    k = 0 the main diagonal
    k > 0 the k-th upper diagonal
    k < 0 the k-th lower diagonal

m, n : int
    shape of the result

5.21. Sparse matrices (scipy.sparse) 1367
format : str, optional
Format of the result. By default (format=None) an appropriate sparse ma-
trix format is returned. This choice is subject to change.

See also:
diags more convenient form of this function
dia_matrix the sparse DIAgonal format.

Examples

```python
>>> from scipy.sparse import spdiags
>>> data = np.array([[1, 2, 3, 4], [1, 2, 3, 4], [1, 2, 3, 4]])
>>> diags = np.array([-1, 2])
>>> spdiags(data, diags, 4, 4).toarray()
array([[1, 0, 3, 0],
       [1, 2, 0, 4],
       [0, 2, 3, 0],
       [0, 0, 3, 4]])
```

scipy.sparse.block_diag(mats, format=None, dtype=None)
Build a block diagonal sparse matrix from provided matrices.

Parameters
mats : sequence of matrices
Input matrices.

format : str, optional
The sparse format of the result (e.g. “csr”). If not given, the matrix is
returned in “coo” format.

dtype : dtype specifier, optional
The data-type of the output matrix. If not given, the dtype is determined
from that of blocks.

Returns
res : sparse matrix

See also:

bmat, diags

Notes
New in version 0.11.0.

Examples

```python
>>> from scipy.sparse import coo_matrix, block_diag
>>> A = coo_matrix([[1, 2], [3, 4]])
>>> B = coo_matrix([[5], [6]])
>>> C = coo_matrix([[7]])
>>> block_diag((A, B, C)).toarray()
array([[1, 2, 0, 0],
       [3, 4, 0, 0],
       [0, 0, 5, 0],
       [0, 0, 6, 0],
       [0, 0, 0, 7]])
```

scipy.sparse.tril(A, k=0, format=None)
Return the lower triangular portion of a matrix in sparse format

Returns the elements on or below the k-th diagonal of the matrix A.

• k = 0 corresponds to the main diagonal
• k > 0 is above the main diagonal
• k < 0 is below the main diagonal

**Parameters**

- **A**: dense or sparse matrix
  - Matrix whose lower triangular portion is desired.
- **k**: integer
  - The top-most diagonal of the lower triangle.
- **format**: string
  - Sparse format of the result, e.g. format="csr", etc.

**Returns**

- **L**: sparse matrix
  - Lower triangular portion of A in sparse format.

**See also:**

- `triu` upper triangle in sparse format

**Examples**

```python
>>> from scipy.sparse import csr_matrix, tril

>>> A = csr_matrix([[1, 2, 0, 0, 3],
                  [4, 5, 0, 6, 7],
                  [0, 0, 8, 9, 0]],
                  dtype='int32')

>>> A.toarray()
array([[1, 2, 0, 0, 3],
       [4, 5, 0, 6, 7],
       [0, 0, 8, 9, 0]])

>>> tril(A).toarray()
array([[1, 0, 0, 0, 0],
       [4, 5, 0, 0, 0],
       [0, 0, 8, 0, 0]])

>>> tril(A).nnz
4

>>> tril(A, k=1).toarray()
array([[1, 2, 0, 0, 0],
       [4, 5, 0, 0, 0],
       [0, 0, 8, 9, 0]])

>>> tril(A, k=-1).toarray()
array([[0, 0, 0, 0, 0],
       [4, 0, 0, 0, 0],
       [0, 0, 0, 0, 0]])

>>> tril(A, format='csc')
<3x5 sparse matrix of type '<class 'numpy.int32'>'
  with 4 stored elements in Compressed Sparse Column format>
```

### scipy.sparse.triu(A, k=0, format=None)

Return the upper triangular portion of a matrix in sparse format

**Returns the elements on or above the k-th diagonal of the matrix A.**

- k = 0 corresponds to the main diagonal
- k > 0 is above the main diagonal
- k < 0 is below the main diagonal

**Parameters**

- **A**: dense or sparse matrix
  - Matrix whose upper triangular portion is desired.
- **k**: integer
  - The bottom-most diagonal of the upper triangle.
- **format**: string
  - Sparse format of the result, e.g. format="csr", etc.

**Returns**

- **L**: sparse matrix
  - Upper triangular portion of A in sparse format.
See also:

tril     lower triangle in sparse format

Examples

```python
>>> from scipy.sparse import csr_matrix, triu
>>> A = csr_matrix([[1, 2, 0, 0, 3], [4, 5, 0, 6, 7], [0, 0, 8, 9, 0]],
                 dtype='int32')
>>> A.toarray()
array([[1, 2, 0, 0, 3],
       [4, 5, 0, 6, 7],
       [0, 0, 8, 9, 0]])
>>> triu(A).toarray()
array([[1, 2, 0, 0, 3],
       [0, 5, 0, 6, 7],
       [0, 0, 8, 9, 0]])
>>> triu(A).nnz
8
>>> triu(A, k=1).toarray()
array([[0, 2, 0, 0, 3],
       [0, 0, 0, 6, 7],
       [0, 0, 0, 9, 0]])
>>> triu(A, k=-1).toarray()
array([[1, 2, 0, 0, 3],
       [4, 5, 0, 6, 7],
       [0, 0, 8, 9, 0]])
>>> triu(A, format='csc')
<3x5 sparse matrix of type '<class 'numpy.int32'>'
  with 8 stored elements in Compressed Sparse Column format>
```

scipy.sparse.bmat((blocks, format=None, dtype=None))

Build a sparse matrix from sparse sub-blocks

Parameters

blocks : array_like
    Grid of sparse matrices with compatible shapes. An entry of None implies an all-zero matrix.

format : {'bsr', 'coo', 'csc', 'csr', 'dia', 'dok', 'lil'}, optional
    The sparse format of the result (e.g. "csr"). By default an appropriate sparse matrix format is returned. This choice is subject to change.

dtype : dtype, optional
    The data-type of the output matrix. If not given, the dtype is determined from that of blocks.

Returns

bmat : sparse matrix

See also:

block_diag, diags

Examples

```python
>>> from scipy.sparse import coo_matrix, bmat
>>> A = coo_matrix([[1, 2], [3, 4]]))
>>> B = coo_matrix([[5], [6]]))
>>> C = coo_matrix([[7]]))
>>> bmat([[A, B], [None, C]]).toarray()
array([[1, 2, 5],
       [3, 4, 6],
       [0, 0, 7]])
```
```python
>>> bmat([[A, None], [None, C]]).toarray()
array([[1, 2, 0],
       [3, 4, 0],
       [0, 0, 7]])
```

`scipy.sparse.hstack` *(blocks, format=None, dtype=None)*
Stack sparse matrices horizontally (column wise)

**Parameters**
- `blocks` sequence of sparse matrices with compatible shapes
- `format` : str
  sparse format of the result (e.g. “csr”) by default an appropriate sparse
  matrix format is returned. This choice is subject to change.
- `dtype` : dtype, optional
  The data-type of the output matrix. If not given, the dtype is determined
  from that of `blocks`.

**See also:**
- `vstack` stack sparse matrices vertically (row wise)

**Examples**
```python
>>> from scipy.sparse import coo_matrix, hstack
>>> A = coo_matrix([[1, 2], [3, 4]])
>>> B = coo_matrix([[5], [6]])
>>> hstack([A, B]).toarray()
array([[1, 2, 5],
       [3, 4, 6]])
```

`scipy.sparse.vstack` *(blocks, format=None, dtype=None)*
Stack sparse matrices vertically (row wise)

**Parameters**
- `blocks` sequence of sparse matrices with compatible shapes
- `format` : str, optional
  sparse format of the result (e.g. “csr”) by default an appropriate sparse
  matrix format is returned. This choice is subject to change.
- `dtype` : dtype, optional
  The data-type of the output matrix. If not given, the dtype is determined
  from that of `blocks`.

**See also:**
- `hstack` stack sparse matrices horizontally (column wise)

**Examples**
```python
>>> from scipy.sparse import coo_matrix, vstack
>>> A = coo_matrix([[1, 2], [3, 4]])
>>> B = coo_matrix([[5], [6]])
>>> vstack([A, B]).toarray()
array([[1, 2],
       [3, 4],
       [5, 6]])
```

`scipy.sparse.rand` *(m, n, density=0.01, format='coo', dtype=None, random_state=None)*
Generate a sparse matrix of the given shape and density with uniformly distributed values.

5.21. Sparse matrices *(scipy.sparse)*
Parameters

- **m, n**: int
  - shape of the matrix

- **density**: real, optional
  - density of the generated matrix: density equal to one means a full matrix, density of 0 means a matrix with no non-zero items.

- **format**: str, optional
  - sparse matrix format.

- **dtype**: dtype, optional
  - type of the returned matrix values.

- **random_state**: {numpy.random.RandomState, int}, optional
  - Random number generator or random seed. If not given, the singleton numpy.random will be used.

Returns

- **res**: sparse matrix

See also:

scipy.sparse.random

Similar function that allows a user-specified random data source.

Notes

Only float types are supported for now.

Examples

```python
csr_matrix = scipy.sparse.random(3, 4, density=0.25, format='csr', random_state=42)
csr_matrix.todense()  # Output: array([[0. , 0.59685016, 0.779691 , 0. ],
                  [0. , 0.       , 0.       , 0.44583275],
                  [0. , 0.       , 0.       , 0.       ]])
scipy.sparse.random(m, n, density=0.01, format='coo', dtype=None, random_state=None, data_rvs=None)
```

Generate a sparse matrix of the given shape and density with randomly distributed values.

Parameters

- **m, n**: int
  - shape of the matrix

- **density**: real, optional
  - density of the generated matrix: density equal to one means a full matrix, density of 0 means a matrix with no non-zero items.

- **format**: str, optional
  - sparse matrix format.

- **dtype**: dtype, optional
  - type of the returned matrix values.

- **random_state**: {numpy.random.RandomState, int}, optional
  - Random number generator or random seed. If not given, the singleton numpy.random will be used. This random state will be used for sampling the sparsity structure, but not necessarily for sampling the values of the structurally nonzero entries of the matrix.

- **data_rvs**: callable, optional
  - Samples a requested number of random values. This function should take a single argument specifying the length of the ndarray that it will return. The structurally nonzero entries of the sparse random matrix will be taken from the array sampled by this function. By default, uniform [0, 1) random
values will be sampled using the same random state as is used for sampling the sparsity structure.

**Returns**  
res : sparse matrix

**Notes**

Only float types are supported for now.

**Examples**

```python
>>> from scipy.sparse import random
>>> from scipy import stats

... class CustomRandomState(object):
...     def randint(self, self, k):
...         i = np.random.randint(k)
...         return i - i % 2
...     rs = CustomRandomState()
>>> rvs = stats.poisson(25, loc=10).rvs
>>> S = random(3, 4, density=0.25, random_state=rs, data_rvs=rvs)
>>> S.A
array([[ 36., 0., 33., 0.],
       [ 0., 0., 0., 0.],
       [ 0., 0., 36., 0.]])
```

Save and load sparse matrices:

```python
scipy.sparse.save_npz (file, matrix[, compressed])  
Save a sparse matrix to a file using .npz format.

load_npz (file)  
Load a sparse matrix from a file using .npz format.
```

```python
scipy.sparse.save_npz (file, matrix, compressed=True)  
Save a sparse matrix to a file using .npz format.

Parameters

- file : str or file-like object
  Either the file name (string) or an open file (file-like object) where the data will be saved. If file is a string, the .npz extension will be appended to the file name if it is not already there.

- matrix : spmatrix (format: ”csc”, ”csr”, ”bsr”, ”dia” or coo”)
  The sparse matrix to save.

- compressed : bool, optional
  Allow compressing the file. Default: True

See also:

- scipy.sparse.load_npz
  Load a sparse matrix from a file using .npz format.

- numpy.save
  Save several arrays into a .npz archive.

- numpy.savez_compressed
  Save several arrays into a compressed .npz archive.

Examples

Store sparse matrix to disk, and load it again:

```python
>>> import scipy.sparse
>>> sparse_matrix = scipy.sparse.csc_matrix(np.array([[0, 0, 3], [4, 0, 0]]))
>>> sparse_matrix
<2x3 sparse matrix of type '<class 'numpy.int64'>'
```
>>> sparse_matrix.todense()
matrix([[0, 0, 3],
        [4, 0, 0]], dtype=int64)

>>> scipy.sparse.save_npz('/tmp/sparse_matrix.npz', sparse_matrix)

>>> sparse_matrix = scipy.sparse.load_npz('/tmp/sparse_matrix.npz')

>>> sparse_matrix
<2x3 sparse matrix of type '<class 'numpy.int64'>'
 with 2 stored elements in Compressed Sparse Column format>

scipy.sparse.load_npz(file)

Load a sparse matrix from a file using .npz format.

Parameters

- **file**: str or file-like object
  Either the file name (string) or an open file (file-like object) where the data
  will be loaded.

- **result**: csc_matrix, csr_matrix, bsr_matrix, dia_matrix or coo_matrix
  A sparse matrix containing the loaded data.

- **IOError**
  If the input file does not exist or cannot be read.

See also:

- **scipy.sparse.save_npz**
  Save a sparse matrix to a file using .npz format.

- **numpy.load**
  Load several arrays from a .npz archive.

Examples

Store sparse matrix to disk, and load it again:

```python
>>> import scipy.sparse
>>> sparse_matrix = scipy.sparse.csc_matrix(np.array([[0, 0, 3], [4, 0, 0]]))
>>> sparse_matrix
<2x3 sparse matrix of type '<class 'numpy.int64'>'
 with 2 stored elements in Compressed Sparse Column format>

>>> sparse_matrix.todense()
matrix([[0, 0, 3],
        [4, 0, 0]], dtype=int64)

>>> scipy.sparse.save_npz('/tmp/sparse_matrix.npz', sparse_matrix)

>>> sparse_matrix = scipy.sparse.load_npz('/tmp/sparse_matrix.npz')

>>> sparse_matrix
<2x3 sparse matrix of type '<class 'numpy.int64'>'
 with 2 stored elements in Compressed Sparse Column format>

>>> sparse_matrix.todense()
matrix([[0, 0, 3],
        [4, 0, 0]], dtype=int64)
```

Sparse matrix tools:
SciPy Reference Guide, Release 1.0.0

**find(A)**

Return the indices and values of the nonzero elements of a matrix

**scipy.sparse.find(A)**

Return the indices and values of the nonzero elements of a matrix

**Parameters**

- **A**: dense or sparse matrix

**Returns**

- **(I,J,V)**: tuple of arrays

  I, J, and V contain the row indices, column indices, and values of the nonzero matrix entries.

**Examples**

```python
>>> from scipy.sparse import csr_matrix, find
>>> A = csr_matrix([[7.0, 8.0, 0], [0, 0, 9.0]])
>>> find(A)
(array([0, 0, 1], dtype=int32), array([0, 1, 2], dtype=int32), array([7., 8., 9.]))
```

Identifying sparse matrices:

- **issparse(x)**

  Is x of a sparse matrix type?

- **isspmatrix(x)**

  Is x of a sparse matrix type?

- **isspmatrix_csc(x)**

  Is x of csc_matrix type?

- **isspmatrix_csr(x)**

  Is x of csr_matrix type?

- **isspmatrix_bsr(x)**

  Is x of a bsr_matrix type?

- **isspmatrix_lil(x)**

  Is x of lil_matrix type?

- **isspmatrix_dok(x)**

  Is x of dok_matrix type?

- **isspmatrix_coo(x)**

  Is x of coo_matrix type?

- **isspmatrix_dia(x)**

  Is x of dia_matrix type?

**scipy.sparse.issparse(x)**

Is x of a sparse matrix type?

**Parameters**

- **x**: object to check for being a sparse matrix

**Returns**

- **bool**: True if x is a sparse matrix, False otherwise

**Notes**

issparse and isspmatrix are aliases for the same function.

**Examples**

```python
>>> from scipy.sparse import csr_matrix, isspmatrix
>>> isspmatrix(csr_matrix([[5]]))
True
```

```python
>>> from scipy.sparse import isspmatrix
>>> isspmatrix(5)
False
```

5.21. Sparse matrices (**scipy.sparse**) 1375
scipy.sparse.isspmatrix(x)
Is x of a sparse matrix type?

Parameters
x          object to check for being a sparse matrix

Returns
bool      True if x is a sparse matrix, False otherwise

Notes
issparse and isspmatrix are aliases for the same function.

Examples

```python
>>> from scipy.sparse import csr_matrix, isspmatrix
>>> isspmatrix(csr_matrix([[5]]))
True
```

```python
>>> from scipy.sparse import isspmatrix
>>> isspmatrix(5)
False
```

scipy.sparse.isspmatrix_csc(x)
Is x of csc_matrix type?

Parameters
x          object to check for being a csc matrix

Returns
bool      True if x is a csc matrix, False otherwise

Examples

```python
>>> from scipy.sparse import csc_matrix, isspmatrix_csc
>>> isspmatrix_csc(csc_matrix([[5]]))
True
```

```python
>>> from scipy.sparse import csc_matrix, csr_matrix, isspmatrix_csc
>>> isspmatrix_csc(csr_matrix([[5]]))
False
```

scipy.sparse.isspmatrix_csr(x)
Is x of csr_matrix type?

Parameters
x          object to check for being a csr matrix

Returns
bool      True if x is a csr matrix, False otherwise

Examples

```python
>>> from scipy.sparse import csr_matrix, isspmatrix_csr
>>> isspmatrix_csr(csr_matrix([[5]]))
True
```

```python
>>> from scipy.sparse import csc_matrix, csr_matrix, isspmatrix_csc
>>> isspmatrix_csc(csc_matrix([[5]]))
False
```
scipy.sparse.isspmatrix_bsr(x)
Is x of a bsr_matrix type?

Parameters
x

Returns
bool
object to check for being a bsr matrix
True if x is a bsr matrix, False otherwise

Examples

```python
>>> from scipy.sparse import bsr_matrix, isspmatrix_bsr
>>> isspmatrix_bsr(bsr_matrix([[5]]))
True
```

```python
>>> from scipy.sparse import bsr_matrix, csr_matrix, isspmatrix_bsr
>>> isspmatrix_bsr(csr_matrix([[5]]))
False
```

scipy.sparse.isspmatrix_lil(x)
Is x of lil_matrix type?

Parameters
x

Returns
bool
object to check for being a lil matrix
True if x is a lil matrix, False otherwise

Examples

```python
>>> from scipy.sparse import lil_matrix, isspmatrix_lil
>>> isspmatrix_lil(lil_matrix([[5]]))
True
```

```python
>>> from scipy.sparse import lil_matrix, csr_matrix, isspmatrix_lil
>>> isspmatrix_lil(csr_matrix([[5]]))
False
```

scipy.sparse.isspmatrix_dok(x)
Is x of dok_matrix type?

Parameters
x

Returns
bool
object to check for being a dok matrix
True if x is a dok matrix, False otherwise

Examples

```python
>>> from scipy.sparse import dok_matrix, isspmatrix_dok
>>> isspmatrix_dok(dok_matrix([[5]]))
True
```

```python
>>> from scipy.sparse import dok_matrix, csr_matrix, isspmatrix_dok
>>> isspmatrix_dok(csr_matrix([[5]]))
False
```

scipy.sparse.isspmatrix_coo(x)
Is x of coo_matrix type?

Parameters
x

object to check for being a coo matrix
Returns bool

True if x is a coo matrix, False otherwise

Examples

```
>>> from scipy.sparse import coo_matrix, isspmatrix_coo
>>> isspmatrix_coo(coo_matrix([[5]]))
True
```

```
>>> from scipy.sparse import coo_matrix, csr_matrix, isspmatrix_coo
>>> isspmatrix_coo(csr_matrix([[5]]))
False
```

scipy.sparse.isspmatrix_dia(x)

Is x of dia_matrix type?

Parameters x

object to check for being a dia matrix

Returns bool

True if x is a dia matrix, False otherwise

Examples

```
>>> from scipy.sparse import dia_matrix, isspmatrix_dia
>>> isspmatrix_dia(dia_matrix([[5]]))
True
```

```
>>> from scipy.sparse import dia_matrix, csr_matrix, isspmatrix_dia
>>> isspmatrix_dia(csr_matrix([[5]]))
False
```

```python
scipy.sparse.csgraph.connected_components
```

Analyze the connected components of a sparse graph

New in version 0.11.0.

**Parameters**

- `csgraph` : array_like or sparse matrix
  The N x N matrix representing the compressed sparse graph. The input `csgraph` will be converted to csr format for the calculation.

- `directed` : bool, optional
  If True (default), then operate on a directed graph: only move from point i to point j along paths `csgraph[i, j]`. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along `csgraph[i, j]` or `csgraph[j, i]`.

- `connection` : str, optional
  - ['weak'|'strong']. For directed graphs, the type of connection to use. Nodes i and j are strongly connected if a path exists both from i to j and from j to i. Nodes i and j are weakly connected if only one of these paths exists. If `directed == False`, this keyword is not referenced.

- `return_labels` : bool, optional
  If True (default), then return the labels for each of the connected components.

**Returns**

- `n_components`: int
  The number of connected components.

- `labels`: ndarray
  The length-N array of labels of the connected components.

**References**

[R15]

```python
scipy.sparse.csgraph.laplacian
```

Return the Laplacian matrix of a directed graph.

**Parameters**

- `csgraph` : array_like or sparse matrix, 2 dimensions
  compressed-sparse graph, with shape (N, N).
normed : bool, optional
If True, then compute normalized Laplacian.

return_diag : bool, optional
If True, then also return an array related to vertex degrees.

use_out_degree : bool, optional
If True, then use out-degree instead of in-degree. This distinction matters
only if the graph is asymmetric. Default: False.

Returns

lap : ndarray or sparse matrix
The N x N laplacian matrix of csgraph. It will be a numpy array (dense) if
the input was dense, or a sparse matrix otherwise.

diag : ndarray, optional
The length-N diagonal of the Laplacian matrix. For the normalized Lapla-
cian, this is the array of square roots of vertex degrees or 1 if the degree is
zero.

Notes

The Laplacian matrix of a graph is sometimes referred to as the “Kirchoff matrix” or the “admittance matrix”,
and is useful in many parts of spectral graph theory. In particular, the eigen-decomposition of the laplacian
matrix can give insight into many properties of the graph.

Examples

```python
>>> from scipy.sparse import csgraph
>>> G = np.arange(5) * np.arange(5)[:, np.newaxis]
>>> G
array([[ 0,  0,  0,  0,  0],
       [ 0,  1,  2,  3,  4],
       [ 0,  2,  4,  6,  8],
       [ 0,  3,  6,  9, 12],
       [ 0,  4,  8, 12, 16]])
>>> csgraph.laplacian(G, normed=False)
array([[ 0,  0,  0,  0,  0],
       [ 0,  9, -2, -3, -4],
       [ 0, -2, 16, -6, -8],
       [ 0, -3, -6, 21, -12],
       [ 0, -4, -8, -12, 24]])
```

scipy.sparse.csgraph.shortest_path(csgraph, method='auto', directed=True, return_predecessors=False, unweighted=False, overwrite=False, indices=None)

Perform a shortest-path graph search on a positive directed or undirected graph.

New in version 0.11.0.

Parameters

- csgraph : array, matrix, or sparse matrix, 2 dimensions
  The N x N array of distances representing the input graph.

- method : string ['auto'|'FW'|'D'], optional
  Algorithm to use for shortest paths. Options are:
  `'auto'` – (default) select the best among ‘FW’, ‘D’, ‘BF’, or ‘J’
  based on the input data.

  ‘FW’ – Floyd-Warshall algorithm. Computational cost is
  approximately $O[N^3]$. The input csgraph
  will be converted to a dense representation.

  ‘D’ – Dijkstra’s algorithm with Fibonacci heaps. Computational
  cost is approximately $O[N(N+k +
\[N \log(N)\], where \(k\) is the average number of connected edges per node. The input csgraph will be converted to a csr representation.

**‘BF’ – Bellman-Ford algorithm. This algorithm can be used when**

weights are negative. If a negative cycle is encountered, an error will be raised. Computational cost is approximately \(O[N (N^2 + k)]\), where \(k\) is the average number of connected edges per node. The input csgraph will be converted to a csr representation.

**‘J’ – Johnson’s algorithm. Like the Bellman-Ford algorithm,**

Johnson’s algorithm is designed for use when the weights are negative. It combines the Bellman-Ford algorithm with Dijkstra’s algorithm for faster computation.

directed : bool, optional
If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i]

return_predecessors : bool, optional
If True, return the size (N, N) predecessor matrix

unweighted : bool, optional
If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.

overwrite : bool, optional
If True, overwrite csgraph with the result. This applies only if method == ‘FW’ and csgraph is a dense, c-ordered array with dtype=float64.

indices : array_like or int, optional
If specified, only compute the paths for the points at the given indices. Incompatible with method == ‘FW’.

Returns
dist_matrix : ndarray
The N x N matrix of distances between graph nodes. dist_matrix[i,j] gives the shortest distance from point i to point j along the graph.

predecessors : ndarray
Returned only if return_predecessors == True. The N x N matrix of predecessors, which can be used to reconstruct the shortest paths. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry predecessors[i, j] gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then predecessors[i, j] = -9999

Raises
NegativeCycleError:
if there are negative cycles in the graph

Notes
As currently implemented, Dijkstra’s algorithm and Johnson’s algorithm do not work for graphs with direction-dependent distances when directed == False. i.e., if csgraph[i,j] and csgraph[j,i] are non-equal edges, method=’D’ may yield an incorrect result.
Dijkstra algorithm using Fibonacci Heaps

New in version 0.11.0.

**Parameters**

- **csgraph**: array, matrix, or sparse matrix, 2 dimensions
  - The N x N array of non-negative distances representing the input graph.
- **directed**: bool, optional
  - If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i]
- **indices**: array_like or int, optional
  - If specified, only compute the paths for the points at the given indices.
- **return_predecessors**: bool, optional
  - If True, return the size (N, N) predecessor matrix
- **unweighted**: bool, optional
  - If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.
- **limit**: float, optional
  - The maximum distance to calculate, must be >= 0. Using a smaller limit will decrease computation time by aborting calculations between pairs that are separated by a distance > limit. For such pairs, the distance will be equal to np.inf (i.e., not connected).

**Returns**

- **dist_matrix**: ndarray
  - The matrix of distances between graph nodes. dist_matrix[i,j] gives the shortest distance from point i to point j along the graph.
- **predecessors**: ndarray
  - Returned only if return_predecessors == True. The matrix of predecessors, which can be used to reconstruct the shortest paths. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry predecessors[i, j] gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then predecessors[i, j] = -9999

**Notes**

As currently implemented, Dijkstra’s algorithm does not work for graphs with direction-dependent distances when directed == False. i.e., if csgraph[i,j] and csgraph[j,i] are not equal and both are nonzero, setting directed=False will not yield the correct result.

Also, this routine does not work for graphs with negative distances. Negative distances can lead to infinite cycles that must be handled by specialized algorithms such as Bellman-Ford’s algorithm or Johnson’s algorithm.

```
scipy.sparse.csgraph.floyd_warshall(csgraph, directed=True, return_predecessors=False, unweighted=False, overwrite=False)
```

Compute the shortest path lengths using the Floyd-Warshall algorithm

New in version 0.11.0.

**Parameters**

- **csgraph**: array, matrix, or sparse matrix, 2 dimensions
  - The N x N array of distances representing the input graph.
- **directed**: bool, optional
  - If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i]
\textbf{return predecessors :} bool, optional

If True, return the size (N, N) predecessor matrix

\textbf{unweighted :} bool, optional

If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.

\textbf{overwrite :} bool, optional

If True, overwrite csgraph with the result. This applies only if csgraph is a dense c-ordered array with dtype=float64.

\textbf{Returns}

\textbf{dist_matrix :} ndarray

The N x N matrix of distances between graph nodes. dist_matrix[i,j] gives the shortest distance from point i to point j along the graph.

\textbf{predecessors :} ndarray

Returned only if return_predecessors == True. The N x N matrix of predecessors, which can be used to reconstruct the shortest paths. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry predecessors[i, j] gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then predecessors[i, j] = -9999

\textbf{Raises}

\textbf{NegativeCycleError:}

if there are negative cycles in the graph

\textbf{scipy.sparse.csgraph.bellman_ford}(csgraph, directed=True, indices=None, return_predecessors=False, unweighted=False)

Compute the shortest path lengths using the Bellman-Ford algorithm.

The Bellman-ford algorithm can robustly deal with graphs with negative weights. If a negative cycle is detected, an error is raised. For graphs without negative edge weights, dijkstra’s algorithm may be faster.

New in version 0.11.0.

\textbf{Parameters}

\textbf{csgraph :} array, matrix, or sparse matrix, 2 dimensions

The N x N array of distances representing the input graph.

\textbf{directed :} bool, optional

If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i]

\textbf{indices :} array_like or int, optional

if specified, only compute the paths for the points at the given indices.

\textbf{return_predecessors :} bool, optional

If True, return the size (N, N) predecessor matrix

\textbf{unweighted :} bool, optional

If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.

\textbf{Returns}

\textbf{dist_matrix :} ndarray

The N x N matrix of distances between graph nodes. dist_matrix[i,j] gives the shortest distance from point i to point j along the graph.

\textbf{predecessors :} ndarray

Returned only if return_predecessors == True. The N x N matrix of predecessors, which can be used to reconstruct the shortest paths. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry predecessors[i, j] gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then predecessors[i, j] = -9999

\textbf{Raises}

\textbf{NegativeCycleError:}

if there are negative cycles in the graph
This routine is specially designed for graphs with negative edge weights. If all edge weights are positive, then Dijkstra’s algorithm is a better choice.

```python
scipy.sparse.csgraph.johnson(csgraph, directed=True, indices=None, return_predecessors=False, unweighted=False)
```

Compute the shortest path lengths using Johnson’s algorithm.

Johnson’s algorithm combines the Bellman-Ford algorithm and Dijkstra’s algorithm to quickly find shortest paths in a way that is robust to the presence of negative cycles. If a negative cycle is detected, an error is raised. For graphs without negative edge weights, dijkstra() may be faster.

New in version 0.11.0.

**Parameters**

- `csgraph` : array, matrix, or sparse matrix, 2 dimensions
  - The N x N array of distances representing the input graph.
- `directed` : bool, optional
  - If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i]
- `indices` : array_like or int, optional
  - If specified, only compute the paths for the points at the given indices.
- `return_predecessors` : bool, optional
  - If True, return the size (N, N) predecessor matrix
- `unweighted` : bool, optional
  - If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.

**Returns**

- `dist_matrix` : ndarray
  - The N x N matrix of distances between graph nodes. dist_matrix[i,j] gives the shortest distance from point i to point j along the graph.
- `predecessors` : ndarray
  - Returned only if return_predecessors == True. The N x N matrix of predecessors, which can be used to reconstruct the shortest paths. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry predecessors[i, j] gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then predecessors[i, j] = -9999

**Raises**

- `NegativeCycleError`: if there are negative cycles in the graph

This routine is specially designed for graphs with negative edge weights. If all edge weights are positive, then Dijkstra’s algorithm is a better choice.

```python
scipy.sparse.csgraph.breadth_first_order(csgraph, i_start, directed=True, return_predecessors=True)
```

Return a breadth-first ordering starting with specified node.

Note that a breadth-first order is not unique, but the tree which it generates is unique.

New in version 0.11.0.

**Parameters**

- `csgraph` : array_like or sparse matrix
  - The N x N compressed sparse graph. The input csgraph will be converted to csr format for the calculation.
- `i_start` : int
The index of starting node.

**directed** : bool, optional
If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].

**return_predecessors** : bool, optional
If True (default), then return the predecessor array (see below).

**Returns**

- **node_array** : ndarray, one dimension
  The breadth-first list of nodes, starting with specified node. The length of node_array is the number of nodes reachable from the specified node.

- **predecessors** : ndarray, one dimension
  Returned only if return_predecessors is True. The length-N list of predecessors of each node in a breadth-first tree. If node i is not in the tree, then its parent is given by predecessors[i]. If node i is not in the tree (and for the parent node) then predecessors[i] = -9999.

**scipy.sparse.csgraph.depth_first_order** (csgraph, i_start, directed=True, return_predecessors=True)
Return a depth-first ordering starting with specified node.

Note that a depth-first order is not unique. Furthermore, for graphs with cycles, the tree generated by a depth-first search is not unique either.

New in version 0.11.0.

**Parameters**

- **csgraph** : array_like or sparse matrix
  The N x N compressed sparse graph. The input csgraph will be converted to csr format for the calculation.

- **i_start** : int
  The index of starting node.

- **directed** : bool, optional
  If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].

- **return_predecessors** : bool, optional
  If True (default), then return the predecessor array (see below).

**Returns**

- **node_array** : ndarray, one dimension
  The depth-first list of nodes, starting with specified node. The length of node_array is the number of nodes reachable from the specified node.

- **predecessors** : ndarray, one dimension
  Returned only if return_predecessors is True. The length-N list of predecessors of each node in a depth-first tree. If node i is not in the tree, then its parent is given by predecessors[i]. If node i is not in the tree (and for the parent node) then predecessors[i] = -9999.

**scipy.sparse.csgraph.breadth_first_tree** (csgraph, i_start, directed=True)
Return the tree generated by a breadth-first search

Note that a breadth-first tree from a specified node is unique.

New in version 0.11.0.

**Parameters**

- **csgraph** : array_like or sparse matrix
  The N x N matrix representing the compressed sparse graph. The input csgraph will be converted to csr format for the calculation.

- **i_start** : int
  The index of starting node.
directed : bool, optional
   If True (default), then operate on a directed graph: only move from point
   i to point j along paths csgraph[i, j]. If False, then find the shortest path
   on an undirected graph: the algorithm can progress from point i to j along
   csgraph[i, j] or csgraph[j, i].

Returns
   cstree : csr matrix
   The N x N directed compressed-sparse representation of the breadth- first
   tree drawn from csgraph, starting at the specified node.

Examples
The following example shows the computation of a depth-first tree over a simple four-component graph, starting
at node 0:

In compressed sparse representation, the solution looks like this:

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import breadth_first_tree
>>> X = csr_matrix([[0, 8, 0, 3],
                  ... [0, 0, 2, 5],
                  ... [0, 0, 0, 6],
                  ... [0, 0, 0, 0]])
>>> Tcsr = breadth_first_tree(X, 0, directed=False)
>>> Tcsr.toarray().astype(int)
array([[0, 8, 0, 3],
       [0, 0, 2, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]])
```

Note that the resulting graph is a Directed Acyclic Graph which spans the graph. A breadth-first tree from a
given node is unique.

```python
scipy.sparse.csgraph.depth_first_tree(csgraph, i_start, directed=True)
```

Return a tree generated by a depth-first search.

Note that a tree generated by a depth-first search is not unique: it depends on the order that the children of each
node are searched.

New in version 0.11.0.

Parameters
   csgraph : array_like or sparse matrix
      The N x N matrix representing the compressed sparse graph. The input
csgraph will be converted to csr format for the calculation.
   i_start : int
      The index of starting node.
   directed : bool, optional
If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].

**Returns**

cstree : csr matrix

The N x N directed compressed-sparse representation of the depth-first tree drawn from csgraph, starting at the specified node.

**Examples**

The following example shows the computation of a depth-first tree over a simple four-component graph, starting at node 0:

```
input graph  | depth first tree from (0)
(0)          | (0)
/ \          | / \          | (3)---5---(1)
3 8          | 8             | (3)           | (1)
/ \          | / \          |
(3)          | (1)          |
/ /          | / /          |
6 2          | 6 2          |
/ /          | / /          |
(2)          | (2)
```

In compressed sparse representation, the solution looks like this:

```
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import depth_first_tree

>>> X = csr_matrix([[0, 8, 0, 3],
                  ...                  ...
                  ...                  ...
                  ...                  ...
                  [0, 0, 0, 0]])

>>> Tcsr = depth_first_tree(X, 0, directed=False)

array([[0, 8, 0, 0],
        [0, 0, 2, 0],
        [0, 0, 0, 6],
        [0, 0, 0, 0]])
```

Note that the resulting graph is a Directed Acyclic Graph which spans the graph. Unlike a breadth-first tree, a depth-first tree of a given graph is not unique if the graph contains cycles. If the above solution had begun with the edge connecting nodes 0 and 3, the result would have been different.

scipy.sparse.csgraph.minimum_spanning_tree(csgraph, overwrite=False)

Return a minimum spanning tree of an undirected graph

A minimum spanning tree is a graph consisting of the subset of edges which together connect all connected nodes, while minimizing the total sum of weights on the edges. This is computed using the Kruskal algorithm.

New in version 0.11.0.

**Parameters**

csgraph : array_like or sparse matrix, 2 dimensions

The N x N matrix representing an undirected graph over N nodes (see notes below).

overwrite : bool, optional

if true, then parts of the input graph will be overwritten for efficiency.

**Returns**

span_tree : csr matrix

The N x N compressed-sparse representation of the undirected minimum spanning tree over the input (see notes below).
Notes
This routine uses undirected graphs as input and output. That is, if graph[i, j] and graph[j, i] are both zero, then nodes i and j do not have an edge connecting them. If either is nonzero, then the two are connected by the minimum nonzero value of the two.

Examples
The following example shows the computation of a minimum spanning tree over a simple four-component graph:

\[
\begin{array}{ccc}
\text{input graph} & \text{minimum spanning tree} \\
(0) & (0) \\
/ & / \\
3 & 8 & 3 \\
/ & / & / \\
(3)---5---(1) & (3)---5---(1) \\
\ \\
/ & / & / \\
6 & 2 & 2 \\
/ & / & / \\
(2) & (2) & (2)
\end{array}
\]

It is easy to see from inspection that the minimum spanning tree involves removing the edges with weights 8 and 6. In compressed sparse representation, the solution looks like this:

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import minimum_spanning_tree

>>> X = csr_matrix([[0, 8, 0, 3],
                  ...                  [0, 0, 2, 5],
                  ...                  [0, 0, 0, 6],
                  ...                  [0, 0, 0, 0]])

>>> Tcsr = minimum_spanning_tree(X)

>>> Tcsr.toarray().astype(int)
array([[0, 0, 0, 3],
       [0, 0, 2, 5],
       [0, 0, 0, 0],
       [0, 0, 0, 0]])
```

scipy.sparse.csgraph.reverse_cuthill_mckee(graph, symmetric_mode=False)

Returns the permutation array that orders a sparse CSR or CSC matrix in Reverse-Cuthill McKee ordering.

It is assumed by default, symmetric_mode=False, that the input matrix is not symmetric and works on the matrix A+A.T. If you are guaranteed that the matrix is symmetric in structure (values of matrix elements do not matter) then set symmetric_mode=True.

Parameters
- **graph**: sparse matrix
  Input sparse in CSC or CSR sparse matrix format.
- **symmetric_mode**: bool, optional
  Is input matrix guaranteed to be symmetric.

Returns
- **perm**: ndarray
  Array of permuted row and column indices.

Notes
New in version 0.15.0.
References

```python
scipy.sparse.csgraph.maximum_bipartite_matching(graph, perm_type='row')
```

Returns an array of row or column permutations that makes the diagonal of a nonsingular square CSC sparse matrix zero free.

Such a permutation is always possible provided that the matrix is nonsingular. This function looks at the structure of the matrix only. The input matrix will be converted to CSC matrix format if necessary.

**Parameters**
- **graph**: sparse matrix
  - Input sparse in CSC format
- **perm_type**: str, {'row', 'column'}
  - Type of permutation to generate.

**Returns**
- **perm**: ndarray
  - Array of row or column permutations.

**Notes**

This function relies on a maximum cardinality bipartite matching algorithm based on a breadth-first search (BFS) of the underlying graph.

New in version 0.15.0.

References

```python
scipy.sparse.csgraph.structural_rank(graph)
```

Compute the structural rank of a graph (matrix) with a given sparsity pattern.

The structural rank of a matrix is the number of entries in the maximum transversal of the corresponding bipartite graph, and is an upper bound on the numerical rank of the matrix. A graph has full structural rank if it is possible to permute the elements to make the diagonal zero-free.

**Parameters**
- **graph**: sparse matrix
  - Input sparse matrix.

**Returns**
- **rank**: int
  - The structural rank of the sparse graph.

New in version 0.19.0.

References

[R16], [R17]

**exception**

```python
scipy.sparse.csgraph.NegativeCycleError
```

Continued on next page
\texttt{reconstruct_path} (csgraph, predecessors[...])  
Construct a tree from a graph and a predecessor list.

\texttt{scipy.sparse.csgraph.construct_dist_matrix} (graph, predecessors, directed=True, null_value=np.inf)  
Construct distance matrix from a predecessor matrix  
New in version 0.11.0.

\textbf{Parameters}  
\texttt{graph} : array_like or sparse  
The N x N matrix representation of a directed or undirected graph. If dense, then non-edges are indicated by zeros or infinities.  
\texttt{predecessors} : array_like  
The N x N matrix of predecessors of each node (see Notes below).  
\texttt{directed} : bool, optional  
If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then operate on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].  
\texttt{null_value} : bool, optional  
Value to use for distances between unconnected nodes. Default is np.inf

\textbf{Returns}  
\texttt{dist_matrix} : ndarray  
The N x N matrix of distances between nodes along the path specified by the predecessor matrix. If no path exists, the distance is zero.

\textbf{Notes}  
The predecessor matrix is of the form returned by \texttt{graph_shortest_path}. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry predecessors[i, j] gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then predecessors[i, j] = -9999

\texttt{scipy.sparse.csgraph.csgraph_from_dense} (graph, null_value=0, nan_null=True, infinity_null=True)  
Construct a CSR-format sparse graph from a dense matrix.  
New in version 0.11.0.

\textbf{Parameters}  
\texttt{graph} : array_like  
Input graph. Shape should be (n_nodes, n_nodes).  
\texttt{null_value} : float or None (optional)  
Value that denotes non-edges in the graph. Default is zero.  
\texttt{infinity_null} : bool  
If True (default), then infinite entries (both positive and negative) are treated as null edges.  
\texttt{nan_null} : bool  
If True (default), then NaN entries are treated as non-edges

\textbf{Returns}  
\texttt{csgraph} : csr_matrix  
Compressed sparse representation of graph,

\texttt{scipy.sparse.csgraph.csgraph_from_masked} (graph)  
Construct a CSR-format graph from a masked array.  
New in version 0.11.0.

\textbf{Parameters}  
\texttt{graph} : MaskedArray  
Input graph. Shape should be (n_nodes, n_nodes).  
\texttt{Returns}  
\texttt{csgraph} : csr_matrix  
Compressed sparse representation of graph,
scipy.sparse.csgraph.csgraph_masked_from_dense(graph, null_value=0, nan_null=True, infinity_null=True, copy=True)

Construct a masked array graph representation from a dense matrix.

New in version 0.11.0.

Parameters

- **graph** : array_like
  Input graph. Shape should be (n_nodes, n_nodes).
- **null_value** : float or None (optional)
  Value that denotes non-edges in the graph. Default is zero.
- **infinity_null** : bool
  If True (default), then infinite entries (both positive and negative) are treated
  as null edges.
- **nan_null** : bool
  If True (default), then NaN entries are treated as non-edges

Returns

- **csgraph** : MaskedArray
  masked array representation of graph

scipy.sparse.csgraph.csgraph_to_dense(csgraph, null_value=0)

Convert a sparse graph representation to a dense representation

New in version 0.11.0.

Parameters

- **csgraph** : csr_matrix, csc_matrix, or lil_matrix
  Sparse representation of a graph.
- **null_value** : float, optional
  The value used to indicate null edges in the dense representation. Default is
  0.

Returns

- **graph** : ndarray
  The dense representation of the sparse graph.

Notes

For normal sparse graph representations, calling csgraph_to_dense with null_value=0 produces an equivalent result to using dense format conversions in the main sparse package. When the sparse representations have repeated values, however, the results will differ. The tools in scipy.sparse will add repeating values to obtain a final value. This function will select the minimum among repeating values to obtain a final value. For example, here we’ll create a two-node directed sparse graph with multiple edges from node 0 to node 1, of weights 2 and 3. This illustrates the difference in behavior:

```python
>>> from scipy.sparse import csr_matrix, csgraph
>>> data = np.array([2, 3])
>>> indices = np.array([1, 1])
>>> indptr = np.array([0, 2, 2])
>>> M = csr_matrix((data, indices, indptr), shape=(2, 2))
>>> M.toarray()
array([[0, 5],
       [0, 0]])
>>> csgraph.csgraph_to_dense(M)
array([[0., 2.],
       [0., 0.]])
```

The reason for this difference is to allow a compressed sparse graph to represent multiple edges between any two nodes. As most sparse graph algorithms are concerned with the single lowest-cost edge between any two nodes, the default scipy.sparse behavior of summing multiple weights does not make sense in this context.

The other reason for using this routine is to allow for graphs with zero-weight edges. Let’s look at the example of a two-node directed graph, connected by an edge of weight zero:
In the first case, the zero-weight edge gets lost in the dense representation. In the second case, we can choose a different null value and see the true form of the graph.

```python
>>> from scipy.sparse import csr_matrix, csgraph

>>> data = np.array([0.0])
>>> indices = np.array([1])
>>> indptr = np.array([0, 1, 1])
>>> M = csr_matrix((data, indices, indptr), shape=(2, 2))
>>> M.toarray()
array([[ 0.,  0.],
       [ 0.,  0.]])

>>> csgraph.csgraph_to_dense(M, np.inf)
array([[ inf, 0. ],
       [ inf,  inf]])
```

Graph Representations

This module uses graphs which are stored in a matrix format. A graph with N nodes can be represented by an (N x N) adjacency matrix G. If there is a connection from node i to node j, then G[i, j] = w, where w is the weight of the connection. For nodes i and j which are not connected, the value depends on the representation:

- for dense array representations, non-edges are represented by G[i, j] = 0, infinity, or NaN.
- for dense masked representations (of type np.ma.MaskedArray), non-edges are represented by masked values. This can be useful when graphs with zero-weight edges are desired.
- for sparse array representations, non-edges are represented by non-entries in the matrix. This sort of sparse representation also allows for edges with zero weights.
As a concrete example, imagine that you would like to represent the following undirected graph:

```
G
(0)       / \  
  1   2   / \  
(2)     (1)
```

This graph has three nodes, where node 0 and 1 are connected by an edge of weight 2, and nodes 0 and 2 are connected by an edge of weight 1. We can construct the dense, masked, and sparse representations as follows, keeping in mind that an undirected graph is represented by a symmetric matrix:

```python
>>> G_dense = np.array([[0, 2, 1],  
                        [2, 0, 0],  
                        [1, 0, 0]])
>>> G_masked = np.ma.masked_values(G_dense, 0)
>>> from scipy.sparse import csr_matrix
>>> G_sparse = csr_matrix(G_dense)

This becomes more difficult when zero edges are significant. For example, consider the situation when we slightly modify the above graph:

```
G2
(0)       / \  
  0   2   / \  
(2)     (1)
```

This is identical to the previous graph, except nodes 0 and 2 are connected by an edge of zero weight. In this case, the dense representation above leads to ambiguities: how can non-edges be represented if zero is a meaningful value? In this case, either a masked or sparse representation must be used to eliminate the ambiguity:

```python
>>> G2_data = np.array([[np.inf, 2, 0],  
                      [2, np.inf, np.inf],  
                      [0, np.inf, np.inf]])
>>> G2_masked = np.ma.masked_invalid(G2_data)
>>> from scipy.sparse.csgraph import csgraph_from_dense
>>> G2_sparse = csgraph_from_dense(G2_data, null_value=np.inf)
>>> G2_sparse.data
array([ 2., 0., 2., 0.])
```

Here we have used a utility routine from the csgraph submodule in order to convert the dense representation to a sparse representation which can be understood by the algorithms in submodule. By viewing the data array, we can see that the zero values are explicitly encoded in the graph.

### Directed vs. Undirected

Matrices may represent either directed or undirected graphs. This is specified throughout the csgraph module by a boolean keyword. Graphs are assumed to be directed by default. In a directed graph, traversal from node i to node j can be accomplished over the edge G[i, j], but not the edge G[j, i]. In a non-directed graph, traversal from node i to node j can be accomplished over either G[i, j] or G[j, i]. If both edges are not null, and the two have unequal weights,
then the smaller of the two is used. Note that a symmetric matrix will represent an undirected graph, regardless of whether the ‘directed’ keyword is set to True or False. In this case, using directed=True generally leads to more efficient computation.

The routines in this module accept as input either scipy.sparse representations (csr, csc, or lil format), masked representations, or dense representations with non-edges indicated by zeros, infinities, and NaN entries.

**Functions**

- `bellman_ford(csgraph[, directed, indices, ...])`  
  Compute the shortest path lengths using the Bellman-Ford algorithm.

- `breadth_first_order(csgraph, i_start[, ...])`  
  Return a breadth-first ordering starting with specified node.

- `breadth_first_tree(csgraph, i_start[, directed])`  
  Return the tree generated by a breadth-first search.

- `connected_components(csgraph[, directed, ...])`  
  Analyze the connected components of a sparse graph.

- `construct_dist_matrix(graph, predecessors[, ...])`  
  Construct distance matrix from a predecessor matrix.

- `csgraph_from_dense(graph[, null_value, ...])`  
  Construct a CSR-format sparse graph from a dense matrix.

- `csgraph_from_masked(graph)`  
  Construct a CSR-format graph from a masked array.

- `csgraph_masked_from_dense(graph[, ...])`  
  Construct a masked array graph representation from a dense matrix.

- `csgraph_to_dense(csgraph[, null_value])`  
  Convert a sparse graph representation to a dense representation.

- `csgraph_to_masked(csgraph)`  
  Convert a sparse graph representation to a masked array representation.

- `depth_first_order(csgraph, i_start[, ...])`  
  Return a depth-first ordering starting with specified node.

- `depth_first_tree(csgraph, i_start[, directed])`  
  Return a tree generated by a depth-first search.

- `dijkstra(csgraph[, directed, indices, ...])`  
  Dijkstra algorithm using Fibonacci Heaps.

- `floyd_warshall(csgraph[, directed, ...])`  
  Compute the shortest path lengths using the Floyd-Warshall algorithm.

- `johnson(csgraph[, directed, indices, ...])`  
  Compute the shortest path lengths using Johnson’s algorithm.

- `laplacian(csgraph[, normed, return_diag, ...])`  
  Return the Laplacian matrix of a directed graph.

- `maximum_bipartite_matching(graph[, perm_type])`  
  Returns an array of row or column permutations that makes the diagonal of a nonsingular square CSC sparse matrix zero free.

- `minimum_spanning_tree(csgraph[, overwrite])`  
  Return a minimum spanning tree of an undirected graph.

- `reconstruct_path(csgraph, predecessors[, ...])`  
  Construct a tree from a graph and a predecessor list.

- `reverse_cuthill_mckee(graph[, symmetric_mode])`  
  Returns the permutation array that orders a sparse CSR or CSC matrix in Reverse-Cuthill McKee ordering.

- `shortest_path(csgraph[, method, directed, ...])`  
  Perform a shortest-path graph search on a positive directed or undirected graph.

- `structural_rank(graph)`  
  Compute the structural rank of a graph (matrix) with a given sparsity pattern.

**Exceptions**

- `NegativeCycleError`

**Sparse linear algebra** ([scipy.sparse.linalg])

**Abstract linear operators**
class scipy.sparse.linalg.LinearOperator (dtype, shape)
Common interface for performing matrix vector products

Many iterative methods (e.g. cg, gmres) do not need to know the individual entries of a matrix to solve a linear system $A\times x=b$. Such solvers only require the computation of matrix vector products, $A\times v$ where $v$ is a dense vector. This class serves as an abstract interface between iterative solvers and matrix-like objects.

To construct a concrete LinearOperator, either pass appropriate callables to the constructor of this class, or subclass it.

A subclass must implement either one of the methods `_matvec` and `_matmat`, and the attributes/properties `shape` (pair of integers) and `dtype` (may be None). It may call the `__init__` on this class to have these attributes validated. Implementing `_matvec` automatically implements `_matmat` (using a naive algorithm) and vice-versa.

Optionally, a subclass may implement `_rmatvec` or `_adjoint` to implement the Hermitian adjoint (conjugate transpose). As with `_matvec` and `_matmat`, implementing either `_rmatvec` or `_adjoint` implements the other automatically. Implementing `_adjoint` is preferable; `_rmatvec` is mostly there for backwards compatibility.

**Parameters**

- `shape`: tuple
  Matrix dimensions $(M,N)$.
- `matvec`: callable f(v)
  Returns $A \times v$.
- `rmatvec`: callable f(v)
  Returns $A^{\dagger} \times v$, where $A^{\dagger}$ is the conjugate transpose of $A$.
- `matmat`: callable f(V)
  Returns $A \times V$, where $V$ is a dense matrix with dimensions $(N,K)$.
- `dtype`: dtype
  Data type of the matrix.

**See also:**

- `aslinearoperator`
  Construct LinearOperators

**Notes**

The user-defined `matvec()` function must properly handle the case where $v$ has shape $(N,)$ as well as the $(N,1)$ case. The shape of the return type is handled internally by LinearOperator.

LinearOperator instances can also be multiplied, added with each other and exponentiated, all lazily: the result of these operations is always a new, composite LinearOperator, that defers linear operations to the original operators and combines the results.

**Examples**

```python
>>> import numpy as np
>>> from scipy.sparse.linalg import LinearOperator
>>> def mv(v):
...     return np.array([2*v[0], 3*v[1]])
...     ...
>>> A = LinearOperator((2,2), matvec=mv)
>>> A
<2x2 _CustomLinearOperator with dtype=float64>
```
```python
>>> A.matvec(np.ones(2))
array([ 2.,  3.])
>>> A * np.ones(2)
array([ 2.,  3.])
```

**LinearOperator.__call__(x)**

**LinearOperator.adjoint()**

Hermitian adjoint.

Returns the Hermitian adjoint of self, aka the Hermitian conjugate or Hermitian transpose. For a complex matrix, the Hermitian adjoint is equal to the conjugate transpose.

Can be abbreviated self.H instead of self.adjoint().

**Returns**

A_H : LinearOperator

Hermitian adjoint of self.

**LinearOperator.dot(x)**

Matrix-matrix or matrix-vector multiplication.

**Parameters**

x : array_like

1-d or 2-d array, representing a vector or matrix.

**Returns**

Ax : array

1-d or 2-d array (depending on the shape of x) that represents the result of applying this linear operator on x.

**LinearOperator.matmat(X)**

Matrix-matrix multiplication.

Performs the operation y=A*X where A is an MxN linear operator and X dense N*K matrix or ndarray.

**Parameters**

X : {matrix, ndarray}

An array with shape (N,K).

**Returns**

Y : {matrix, ndarray}

A matrix or ndarray with shape (M,K) depending on the type of the X argument.

**Notes**

This matmat wraps any user-specified matmat routine or overridden _matmat method to ensure that y has the correct type.
LinearOperator.matvec(x)
Matrix-vector multiplication.
Performs the operation $y = A^T x$ where $A$ is an MxN linear operator and $x$ is a column vector or 1-d array.

**Parameters**
- x : {matrix, ndarray}
  An array with shape (N,) or (N,1).

**Returns**
- y : {matrix, ndarray}
  A matrix or ndarray with shape (M,) or (M,1) depending on the type and shape of the $x$ argument.

**Notes**
This matvec wraps the user-specified matvec routine or overridden _matvec method to ensure that $y$ has the correct shape and type.

LinearOperator.rmatvec(x)
Adjoint matrix-vector multiplication.
Performs the operation $y = A^H x$ where $A$ is an MxN linear operator and $x$ is a column vector or 1-d array.

**Parameters**
- x : {matrix, ndarray}
  An array with shape (M,) or (M,1).

**Returns**
- y : {matrix, ndarray}
  A matrix or ndarray with shape (N,) or (N,1) depending on the type and shape of the $x$ argument.

**Notes**
This rmatvec wraps the user-specified rmatvec routine or overridden _rmatvec method to ensure that $y$ has the correct shape and type.

LinearOperator.transpose()
Transpose this linear operator.
Returns a LinearOperator that represents the transpose of this one. Can be abbreviated self.T instead of self.transpose().

scipy.sparse.linalg.aslinearoperator(A)
Return $A$ as a LinearOperator.

`A` may be any of the following types:

- ndarray
- matrix
- sparse matrix (e.g. csr_matrix, lil_matrix, etc.)
- LinearOperator
- An object with .shape and .matvec attributes

See the LinearOperator documentation for additional information.

**Examples**

```python
>>> from scipy.sparse.linalg import aslinearoperator
>>> M = np.array([[1,2,3],[4,5,6]], dtype=np.int32)
>>> aslinearoperator(M)
<2x3 MatrixLinearOperator with dtype=int32>
```

Matrix Operations
**inv**

Compute the inverse of a sparse matrix

**Parameters**

A : (M, M) ndarray or sparse matrix

**Returns**

Ainv : (M, M) ndarray or sparse matrix

inverse of A

**Notes**

This computes the sparse inverse of A. If the inverse of A is expected to be non-sparse, it will likely be faster to convert A to dense and use scipy.linalg.inv.

**Examples**

```python
>>> from scipy.sparse import csc_matrix
>>> A = csc_matrix([[1., 0.], [1., 2.]])
>>> Ainv = inv(A)
>>> Ainv
<2x2 sparse matrix of type '<class 'numpy.float64'>'
    with 3 stored elements in Compressed Sparse Column format>
>>> A.dot(Ainv)
<2x2 sparse matrix of type '<class 'numpy.float64'>'
    with 2 stored elements in Compressed Sparse Column format>
>>> A.dot(Ainv).todense()
matrix([[ 1., 0.],
        [ 0., 1.]])
```

New in version 0.12.0.

**expm**

Compute the matrix exponential using Pade approximation.

**Parameters**

A : (M, M) array_like or sparse matrix

**Returns**

expA : (M, M) ndarray

Matrix exponential of A

**Notes**

This is algorithm (6.1) which is a simplification of algorithm (5.1).

New in version 0.12.0.

**References**

[R22]

**Examples**

```python
>>> from scipy.sparse import csc_matrix
>>> A = csc_matrix([[1, 0, 0], [0, 2, 0], [0, 0, 3]])
>>> A.todense()
```
matrix([[1, 0, 0],
        [0, 2, 0],
        [0, 0, 3]], dtype=int64)
>>> Aexp = expm(A)
>>> Aexp
<3x3 sparse matrix of type '<class 'numpy.float64'>'
with 3 stored elements in Compressed Sparse Column format>
>>> Aexp.todense()
matrix([[ 2.71828183, 0. , 0. ],
        [ 0. , 7.3890561 , 0. ],
        [ 0. , 0. , 20.08553692]])

scipy.sparse.linalg.expm_multiply(A, B, start=None, stop=None, num=None, endpoint=None)
Compute the action of the matrix exponential of A on B.

Parameters

A : transposable linear operator
    The operator whose exponential is of interest.
B : ndarray
    The matrix or vector to be multiplied by the matrix exponential of A.
start : scalar, optional
    The starting time point of the sequence.
stop : scalar, optional
    The end time point of the sequence, unless endpoint is set to False. In that case, the sequence consists of all but the last of num + 1 evenly spaced time points, so that stop is excluded. Note that the step size changes when endpoint is False.
num : int, optional
    Number of time points to use.
endpoint : bool, optional
    If True, stop is the last time point. Otherwise, it is not included.

Returns

expm_A_B : ndarray
    The result of the action $e^{tA}B$.

Notes

The optional arguments defining the sequence of evenly spaced time points are compatible with the arguments of numpy.linspace.

The output ndarray shape is somewhat complicated so I explain it here. The ndim of the output could be either 1, 2, or 3. It would be 1 if you are computing the expm action on a single vector at a single time point. It would be 2 if you are computing the expm action on a vector at multiple time points, or if you are computing the expm action on a matrix at a single time point. It would be 3 if you want the action on a matrix with multiple columns at multiple time points. If multiple time points are requested, expm_A_B[0] will always be the action of the expm at the first time point, regardless of whether the action is on a vector or a matrix.

[R23], [R24]

Examples

>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import expm, expm_multiply
>>> A = csc_matrix([[1, 0], [0, 1]])
>>> A.todense()
matrix([[1, 0],
        [0, 1]], dtype=int64)
>>> B = np.array([np.exp(-1.), np.exp(-2.)])

5.21. Sparse matrices (scipy.sparse)
Matrix norms

\[
\text{norm}(x[, \ ord, \ axis]) \quad \text{Norm of a sparse matrix}
\]
\[
\text{onenormest}(A[, t, \ itmax, \ compute_v, \ compute_w]) \quad \text{Compute a lower bound of the 1-norm of a sparse matrix.}
\]

\text{scipy.sparse.linalg.norm}(x, \ ord=\text{None}, \ axis=\text{None})

Norm of a sparse matrix

This function is able to return one of seven different matrix norms, depending on the value of the \text{ord} parameter.

**Parameters**

- \text{x} : a sparse matrix
  - Input sparse matrix.
- \text{ord} : {non-zero int, inf, -inf, ‘fro’}, optional
  - Order of the norm (see table under Notes). \text{inf} means \text{numpy’s inf} object.
- \text{axis} : {int, 2-tuple of ints, None}, optional
  - If \text{axis} is an integer, it specifies the axis of \text{x} along which to compute the vector norms. If \text{axis} is a 2-tuple, it specifies the axes that hold 2-D matrices, and the matrix norms of these matrices are computed. If \text{axis} is None then either a vector norm (when \text{x} is 1-D) or a matrix norm (when \text{x} is 2-D) is returned.

**Returns**

- \text{n} : float or ndarray

**Notes**

Some of the \text{ord} are not implemented because some associated functions like, \text{_multi_svd_norm}, are not yet available for sparse matrix.

This docstring is modified based on \text{numpy.linalg.norm}. https://github.com/numpy/numpy/blob/master/numpy/linalg/linalg.py

The following norms can be calculated:
The Frobenius norm is given by [R38]:

\[ \|A\|_F = \left( \sum_{i,j} \text{abs}(a_{i,j})^2 \right)^{1/2} \]

### References

[R38]

### Examples

```python
>>> from scipy.sparse import *
>>> import numpy as np
>>> from scipy.sparse.linalg import norm
>>> a = np.arange(9) - 4
>>> a
array([-4, -3, -2, -1, 0, 1, 2, 3, 4])
>>> b = a.reshape((3, 3))
>>> b
array([[-4, -3, -2],
       [-1,  0,  1],
       [ 2,  3,  4]])
```

```python
>>> b = csr_matrix(b)
>>> norm(b)
7.745966692414834
>>> norm(b, 'fro')
7.745966692414834
>>> norm(b, np.inf)
9
>>> norm(b, -np.inf)
2
>>> norm(b, 1)
7
>>> norm(b, -1)
6
```

scipy.sparse.linalg.onenormest \(A, t=2, \text{itmax}=5, \text{compute}_v=False, \text{compute}_w=False\)

Compute a lower bound of the 1-norm of a sparse matrix.

**Parameters**

- \(A\) : ndarray or other linear operator
  - A linear operator that can be transposed and that can produce matrix products.
- \(t\) : int, optional
  - A positive parameter controlling the tradeoff between accuracy versus time and memory usage. Larger values take longer and use more memory but give more accurate output.
itmax : int, optional

Use at most this many iterations.

compute_v : bool, optional

Request a norm-maximizing linear operator input vector if True.

compute_w : bool, optional

Request a norm-maximizing linear operator output vector if True.

Returns

est : float

An underestimate of the 1-norm of the sparse matrix.

v : ndarray, optional

The vector such that \|Av\|_1 = est*\|v\|_1. It can be thought of as an input to the linear operator that gives an output with particularly large norm.

w : ndarray, optional

The vector Av which has relatively large 1-norm. It can be thought of as an output of the linear operator that is relatively large in norm compared to the input.

Notes

This is algorithm 2.4 of [1].

In [2] it is described as follows. “This algorithm typically requires the evaluation of about 4t matrix-vector products and almost invariably produces a norm estimate (which is, in fact, a lower bound on the norm) correct to within a factor 3.”

New in version 0.13.0.

[R39], [R40]

Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import onenormest

A = csc_matrix([[1., 0., 0.], [5., 8., 2.], [0., -1., 0.]], dtype=float)

A.todense()
matrix([[ 1., 0., 0.],
        [ 5., 8., 2.],
        [ 0., -1., 0.]])

onenormest(A)
9.0

np.linalg.norm(A.todense(), ord=1)
9.0
```

Solving linear problems

Direct methods for linear equation systems:

spsolve(A, b[, permc_spec, use_umfpack])

Solve the sparse linear system Ax=b, where b may be a vector or a matrix.

spsolve_triangular(A, b[, lower, ...])

Solve the equation A x = b for x, assuming A is a triangular matrix.

factorized(A)

Return a function for solving a sparse linear system, with A pre-factorized.

MatrixRankWarning

Continued on next page
use_solver(**kwargs)  
Select default sparse direct solver to be used.

scipy.sparse.linalg.spsolve \((A, \ b, \ \text{permc_spec}=\text{None}, \ \text{use_umfpack}=\text{True})\)

Solve the sparse linear system \(Ax=b\), where \(b\) may be a vector or a matrix.

**Parameters**

- \(A\) : ndarray or sparse matrix
  The square matrix \(A\) will be converted into CSC or CSR form
- \(b\) : ndarray or sparse matrix
  The matrix or vector representing the right hand side of the equation. If a vector, \(b\.shape\) must be \((n,)\) or \((n, 1)\).
- \text{permc_spec} : str, optional
  How to permute the columns of the matrix for sparsity preservation. (default: ‘COLAMD’)
  - \text{NATURAL} : natural ordering
  - \text{MMD_ATA} : minimum degree ordering on the structure of \(A^T A\)
  - \text{MMD_AT_PLUS_A} : minimum degree ordering on the structure of \(A^T + A\)
  - \text{COLAMD} : approximate minimum degree column ordering

- \text{use_umfpack} : bool, optional
  If True (default) then use umfpack for the solution. This is only referenced if \(b\) is a vector and scikit-umfpack is installed.

**Returns**

- \(x\) : ndarray or sparse matrix
  the solution of the sparse linear equation. If \(b\) is a vector, then \(x\) is a vector of size \(A\.shape[1]\) If \(b\) is a matrix, then \(x\) is a matrix of size \((A\.shape[1], b\.shape[1])\)

**Notes**

For solving the matrix expression \(AX = B\), this solver assumes the resulting matrix \(X\) is sparse, as is often the case for very sparse inputs. If the resulting \(X\) is dense, the construction of this sparse result will be relatively expensive. In that case, consider converting \(A\) to a dense matrix and using scipy.linalg.solve or its variants.

**Examples**

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import spsolve
>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
>>> B = csc_matrix([[2, 0], [-1, 0], [2, 0]], dtype=float)
>>> x = spsolve(A, B)
>>> np.allclose(A.dot(x).todense(), B.todense())
True
```

scipy.sparse.linalg.spsolve_triangular \((A, \ b, \ \text{lower=False}, \ \text{overwrite_A=False}, \ \text{overwrite_b=False})\)

Solve the equation \(A x = b\) for \(x\), assuming \(A\) is a triangular matrix.

**Parameters**

- \(A\) : (M, M) sparse matrix
  A sparse square triangular matrix. Should be in CSR format.
- \(b\) : (M,) or (M, N) array_like
  Right-hand side matrix in \(A x = b\)
- \text{lower} : bool, optional
  Whether \(A\) is a lower or upper triangular matrix. Default is lower triangular matrix.

- \text{overwrite_A} : bool, optional
  Whether to overwrite \(A\) during the solve. Only relevant if \(A\) is dense.

5.21. Sparse matrices (scipy.sparse)  
1403
Allow changing \( A \). The indices of \( A \) are going to be sorted and zero entries are going to be removed. Enabling gives a performance gain. Default is False.

- **overwrite_b**: bool, optional
  Allow overwriting data in \( b \). Enabling gives a performance gain. Default is False. If \( overwrite_b \) is True, it should be ensured that \( b \) has an appropriate dtype to be able to store the result.

- **Returns**
  - \( x \): (M,) or (M, N) ndarray
  Solution to the system \( A x = b \). Shape of return matches shape of \( b \).

- **Raises**
  - LinAlgError
    If \( A \) is singular or not triangular.
  - ValueError
    If shape of \( A \) or shape of \( b \) do not match the requirements.

**Notes**
New in version 0.19.0.

**Examples**

```python
given
scipy.sparse.linalg.factorized(A)
Return a function for solving a sparse linear system, with A pre-factorized.

- **Parameters**
  - \( A \): (N, N) array_like
    Input.

- **Returns**
  - \( solve \): callable
    To solve the linear system of equations given in \( A \), the \( solve \) callable should be passed an ndarray of shape (N,).

- **Examples**

```python
given
```python
>>> from scipy.sparse.linalg import factorized
>>> A = np.array([[  3. ,   2. ,  -1. ],
...                [   2. ,  -2. ,   4. ],
...                [-1. ,   0.5, -1. ]])
>>> solve = factorized(A) # Makes LU decomposition.
>>> rhsl = np.array([1., -2., 0])
>>> solve(rhsl) # Uses the LU factors.
array([ 1., -2., -2.])
```python

**exception**
scipy.sparse.linalg.MatrixRankWarning

**scipy.sparse.linalg.use_solver(**kw_args**)**
Select default sparse direct solver to be used.

- **Parameters**
  - useUmfpack: bool, optional
    Use UMFPACK over SuperLU. Has effect only if scikits.umfpack is installed. Default: True
  - assumeSortedIndices: bool, optional
Allow UMFPACK to skip the step of sorting indices for a CSR/CSC matrix. Has effect only if useUmfpack is True and scikits.umfpack is installed. Default: False

Notes
The default sparse solver is umfpack when available (scikits.umfpack is installed). This can be changed by passing useUmfpack = False, which then causes the always present SuperLU based solver to be used.

Umfpack requires a CSR/CSC matrix to have sorted column/row indices. If sure that the matrix fulfills this, pass assumeSortedIndices=True to gain some speed.

Iterative methods for linear equation systems:

- **bicg** *(A, b[, x0, tol, maxiter, M, callback])*
  Use BIConjugate Gradient iteration to solve $Ax = b$.

- **bicgstab** *(A, b[, x0, tol, maxiter, M, callback])*
  Use BIConjugate Gradient STABilized iteration to solve $Ax = b$.

- **cg** *(A, b[, x0, tol, maxiter, M, callback])*
  Use Conjugate Gradient iteration to solve $Ax = b$.

- **cgs** *(A, b[, x0, tol, maxiter, M, callback])*
  Use Conjugate Gradient Squared iteration to solve $Ax = b$.

- **gmres** *(A, b[, x0, tol, restart, maxiter, M, ...])*
  Use Generalized Minimal RESidual iteration to solve $Ax = b$.

- **lgmres** *(A, b[, x0, tol, maxiter, M, ...])*
  Solve a matrix equation using the LGMRES algorithm.

- **minres** *(A, b[, x0, shift, tol, maxiter, M, ...])*
  Use MINimum RESidual iteration to solve $Ax=b$.

- **qmr** *(A, b[, x0, tol, maxiter, M1, M2, callback])*
  Use Quasi-Minimal Residual iteration to solve $Ax = b$.

- **gcrotmk** *(A, b[, x0, tol, maxiter, M, ...])*
  Solve a matrix equation using flexible GCROT(m,k) algorithm.

```python
scipy.sparse.linalg.bicg(A, b, x0=None, tol=1e-05, maxiter=None, M=None, callback=None)
```

Use BIConjugate Gradient iteration to solve $Ax = b$.

**Parameters**

- **A** : {sparse matrix, dense matrix, LinearOperator}
  The real or complex N-by-N matrix of the linear system. It is required that the linear operator can produce $Ax$ and $A^T x$.

- **b** : {array, matrix}
  Right hand side of the linear system. Has shape (N,) or (N,1).

**Returns**

- **x** : {array, matrix}
  The converged solution.

- **info** : integer
  Provides convergence information:
  - 0 : successful exit
  - >0 : convergence to tolerance not achieved, number of iterations <0 : illegal input or breakdown

**Other Parameters**

- **x0** : {array, matrix}
  Starting guess for the solution.

- **tol** : float
  Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below tol.

- **maxiter** : integer
  Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.

- **M** : {sparse matrix, dense matrix, LinearOperator}
  Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of conver-

5.21. Sparse matrices (**scipy.sparse**)
gence, which implies that fewer iterations are needed to reach a given error tolerance.

**callback** : function
User-supplied function to call after each iteration. It is called as callback(xk), where xk is the current solution vector.

scipy.sparse.linalg.bicgstab(A, b, x0=None, tol=1e-05, maxiter=None, M=None, callback=None)

Use BiConjugate Gradient STABilized iteration to solve $Ax = b$.

**Parameters**
- **A** : {sparse matrix, dense matrix, LinearOperator}
  The real or complex N-by-N matrix of the linear system.
- **b** : {array, matrix}
  Right hand side of the linear system. Has shape (N,) or (N,1).

**Returns**
- **x** : {array, matrix}
  The converged solution.
- **info** : integer
  Provides convergence information:
  - 0 : successful exit
  - >0 : convergence to tolerance not achieved, number of iterations
  - <0 : illegal input or breakdown

**Other Parameters**
- **x0** : {array, matrix}
  Starting guess for the solution.
- **tol** : float
  Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below tol.
- **maxiter** : integer
  Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.
- **M** : {sparse matrix, dense matrix, LinearOperator}
  Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.
- **callback** : function
  User-supplied function to call after each iteration. It is called as callback(xk), where xk is the current solution vector.

scipy.sparse.linalg.cg(A, b, x0=None, tol=1e-05, maxiter=None, M=None, callback=None)

Use Conjugate Gradient iteration to solve $Ax = b$.

**Parameters**
- **A** : {sparse matrix, dense matrix, LinearOperator}
  The real or complex N-by-N matrix of the linear system. A must represent a hermitian, positive definite matrix.
- **b** : {array, matrix}
  Right hand side of the linear system. Has shape (N,) or (N,1).

**Returns**
- **x** : {array, matrix}
  The converged solution.
- **info** : integer
  Provides convergence information:
  - 0 : successful exit
  - >0 : convergence to tolerance not achieved, number of iterations
  - <0 : illegal input or breakdown

**Other Parameters**
- **x0** : {array, matrix}
  Starting guess for the solution.
- **tol** : float
Tolerance to achieve. The algorithm terminates when either the relative or
the absolute residual is below $tol$.

**maxiter** : integer
Maximum number of iterations. Iteration will stop after maxiter steps even
if the specified tolerance has not been achieved.

**M** : {sparse matrix, dense matrix, LinearOperator}
Preconditioner for $A$. The preconditioner should approximate the inverse
of $A$. Effective preconditioning dramatically improves the rate of conver-
gence, which implies that fewer iterations are needed to reach a given error
tolerance.

**callback** : function
User-supplied function to call after each iteration. It is called as call-
back(xk), where xk is the current solution vector.

**Parameters**

$A$ : {sparse matrix, dense matrix, LinearOperator}
The real-valued $N$-by-$N$ matrix of the linear system.

$b$ : {array, matrix}
Right hand side of the linear system. Has shape $(N,)$ or $(N,1)$.

**Returns**

$x$ : {array, matrix}
The converged solution.

**info** : integer
Provides convergence information:

- $0$ : successful exit
- $>0$ : convergence to tolerance not achieved, number of iterations $<0$ : illegal input or break-
down

**Other Parameters**

$x0$ : {array, matrix}
Starting guess for the solution.

tol : float
Tolerance to achieve. The algorithm terminates when either the relative or
the absolute residual is below $tol$.

**maxiter** : integer
Maximum number of iterations. Iteration will stop after maxiter steps even
if the specified tolerance has not been achieved.

**M** : {sparse matrix, dense matrix, LinearOperator}
Preconditioner for $A$. The preconditioner should approximate the inverse
of $A$. Effective preconditioning dramatically improves the rate of conver-
gence, which implies that fewer iterations are needed to reach a given error
tolerance.

**callback** : function
User-supplied function to call after each iteration. It is called as call-
back(xk), where xk is the current solution vector.

**Parameters**

$A$ : {sparse matrix, dense matrix, LinearOperator}
The real or complex $N$-by-$N$ matrix of the linear system.

$b$ : {array, matrix}
Right hand side of the linear system. Has shape $(N,)$ or $(N,1)$.

**Returns**

$x$ : {array, matrix}
The converged solution.

**info** : int
Provides convergence information:

- 0 : successful exit
- >0 : convergence to tolerance not achieved, number of iterations
- <0 : illegal input or breakdown

Other Parameters

**x0** : {array, matrix}
Starting guess for the solution (a vector of zeros by default).

**tol** : float
Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below tol.

**restart** : int, optional
Number of iterations between restarts. Larger values increase iteration cost, but may be necessary for convergence. Default is 20.

**maxiter** : int, optional
Maximum number of iterations (restart cycles). Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.

**M** : {sparse matrix, dense matrix, LinearOperator}
Inverse of the preconditioner of A. M should approximate the inverse of A and be easy to solve for (see Notes). Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance. By default, no preconditioner is used.

**callback** : function
User-supplied function to call after each iteration. It is called as callback(rk), where rk is the current residual vector.

**restrt** : int, optional
DEPRECATED - use restart instead.

See also:

*LinearOperator*

Notes

A preconditioner, P, is chosen such that P is close to A but easy to solve for. The preconditioner parameter required by this routine is $M = P^{-1}$. The inverse should preferably not be calculated explicitly. Rather, use the following template to produce M:

```python
# Construct a linear operator that computes P^-1 * x.
import scipy.sparse.linalg as spla
M_x = lambda x: spla.spsolve(P, x)
M = spla.LinearOperator((n, n), M_x)
```

Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import gmres
>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
>>> b = np.array([2, 4, -1], dtype=float)
>>> x, exitCode = gmres(A, b)
>>> print(exitCode)  # 0 indicates successful convergence
0
>>> np.allclose(A.dot(x), b)
True
```
scipy.sparse.linalg.lgmres(A, b, x0=None, tol=1e-05, maxiter=1000, M=None, callback=None, inner_m=30, outer_k=3, outer_v=None, store_outer_Av=True, prepend_outer_v=False)

Solve a matrix equation using the LGMRES algorithm.

The LGMRES algorithm [R28] [R29] is designed to avoid some problems in the convergence in restarted GMRES, and often converges in fewer iterations.

**Parameters**

- **A**: {sparse matrix, dense matrix, LinearOperator}
  - The real or complex N-by-N matrix of the linear system.
- **b**: {array, matrix}
  - Right hand side of the linear system. Has shape (N,) or (N,1).
- **x0**: {array, matrix}
  - Starting guess for the solution.
- **tol**: float, optional
  - Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below tol.
- **maxiter**: int, optional
  - Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.
- **M**: {sparse matrix, dense matrix, LinearOperator}, optional
  - Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.
- **callback**: function, optional
  - User-supplied function to call after each iteration. It is called as callback(xk), where xk is the current solution vector.
- **inner_m**: int, optional
  - Number of inner GMRES iterations per each outer iteration.
- **outer_k**: int, optional
  - Number of vectors to carry between inner GMRES iterations. According to [R28], good values are in the range of 1...3. However, note that if you want to use the additional vectors to accelerate solving multiple similar problems, larger values may be beneficial.
- **outer_v**: list of tuples, optional
  - List containing tuples (v, Av) of vectors and corresponding matrix-vector products, used to augment the Krylov subspace, and carried between inner GMRES iterations. The element Av can be None if the matrix-vector product should be re-evaluated. This parameter is modified in-place by lgmres, and can be used to pass “guess” vectors in and out of the algorithm when solving similar problems.
- **store_outer_Av**: bool, optional
  - Whether LGMRES should store also A*v in addition to vectors v in the outer_v list. Default is True.
- **prepend_outer_v**: bool, optional
  - Whether to put outer_v augmentation vectors before Krylov iterates. In standard LGMRES, prepend_outer_v=False.

**Returns**

- **x**: array or matrix
  - The converged solution.
- **info**: int
  - Provides convergence information:
    * 0: successful exit
    * >0: convergence to tolerance not achieved, number of iterations
    * <0: illegal input or breakdown

5.21. Sparse matrices (`scipy.sparse`)
Notes

The LGMRES algorithm [R28] [R29] is designed to avoid the slowing of convergence in restarted GMRES, due to alternating residual vectors. Typically, it often outperforms GMRES(m) of comparable memory requirements by some measure, or at least is not much worse.

Another advantage in this algorithm is that you can supply it with ‘guess’ vectors in the outer_v argument that augment the Krylov subspace. If the solution lies close to the span of these vectors, the algorithm converges faster. This can be useful if several very similar matrices need to be inverted one after another, such as in Newton-Krylov iteration where the Jacobian matrix often changes little in the nonlinear steps.

Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import lgmres

>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
>>> b = np.array([2, 4, -1], dtype=float)
>>> x, exitCode = lgmres(A, b)
>>> print(exitCode)  # 0 indicates successful convergence
0
>>> np.allclose(A.dot(x), b)
True
```

scipy.sparse.linalg.minres (A, b, x0=None, shift=0.0, tol=1e-05, maxiter=None, M=None, callback=None, show=False, check=False)

Use MINimum RESidual iteration to solve Ax=b

MINRES minimizes norm(A*x - b) for a real symmetric matrix A. Unlike the Conjugate Gradient method, A can be indefinite or singular.

If shift != 0 then the method solves (A - shift*I)x = b

**Parameters**

- A : (sparse matrix, dense matrix, LinearOperator)
  The real symmetric N-by-N matrix of the linear system
- b : (array, matrix)
  Right hand side of the linear system. Has shape (N,) or (N,1).
- x0 : (array, matrix)
  Starting guess for the solution.
- tol : float
  Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below tol.
- maxiter : integer
  Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.
- M : (sparse matrix, dense matrix, LinearOperator)

**Returns**

- x : (array, matrix)
  The converged solution.
- info : integer
  Provides convergence information:
  0 : successful exit >0 : convergence to tolerance not achieved, number of iterations <0 : illegal input or breakdown

**Other Parameters**

- shift : number
  Shift value for simple shift
- show : boolean
  Display information when exit code is 0
- check : boolean
  Checksanity on each iteration
- callback : callable
  Closure to monitor or modify the residual
```
Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.

**callback** : function

User-supplied function to call after each iteration. It is called as `callback(xk)`, where `xk` is the current solution vector.

### Notes

THIS FUNCTION IS EXPERIMENTAL AND SUBJECT TO CHANGE!

### References

**Solution of sparse indefinite systems of linear equations,**  
https://web.stanford.edu/group/SOL/software/minres/

This file is a translation of the following MATLAB implementation:  
https://web.stanford.edu/group/SOL/software/minres/minres-matlab.zip

**scipy.sparse.linalg.qmr** *(A, b, x0=None, tol=1e-05, maxiter=None, M1=None, M2=None, callback=None)*

Use Quasi-Minimal Residual iteration to solve \(Ax = b\).

**Parameters**

- **A** : {sparse matrix, dense matrix, LinearOperator}  
The real-valued N-by-N matrix of the linear system. It is required that the linear operator can produce \(Ax\) and \(A^T x\).

- **b** : {array, matrix}  
Right hand side of the linear system. Has shape \((N,)\) or \((N,1)\).

**Returns**

- **x** : {array, matrix}  
The converged solution.

- **info** : integer

  Provides convergence information:

  - 0 : successful exit
  - >0 : convergence to tolerance not achieved, number of iterations <0 : illegal input or breakdown

**Other Parameters**

- **x0** : {array, matrix}  
Starting guess for the solution.

- **tol** : float  
Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below `tol`.

- **maxiter** : integer  
Maximum number of iterations. Iteration will stop after `maxiter` steps even if the specified tolerance has not been achieved.

- **M1** : {sparse matrix, dense matrix, LinearOperator}  
Left preconditioner for A.

- **M2** : {sparse matrix, dense matrix, LinearOperator}  
Right preconditioner for A. Used together with the left preconditioner \(M1\). The matrix \(M1*A*M2\) should have better conditioned than \(A\) alone.

- **callback** : function

  User-supplied function to call after each iteration. It is called as `callback(xk)`, where `xk` is the current solution vector.

**See also:**

*LinearOperator*
Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import qmr

>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
>>> b = np.array([2, 4, -1], dtype=float)

>>> x, exitCode = qmr(A, b)

>>> print(exitCode)  # 0 indicates successful convergence
0
>>> np.allclose(A.dot(x), b)
True
```

scipy.sparse.linalg.gcrotmk

Solve a matrix equation using flexible GCROT(m,k) algorithm.

**Parameters**

- **A**: {sparse matrix, dense matrix, LinearOperator}
  The real or complex N-by-N matrix of the linear system.
- **b**: {array, matrix}
  Right hand side of the linear system. Has shape (N,) or (N,1).
- **x0**: {array, matrix}
  Starting guess for the solution.
- **tol**: float, optional
  Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below tol.
- **maxiter**: int, optional
  Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.
- **M**: {sparse matrix, dense matrix, LinearOperator}, optional
  Preconditioner for A. The preconditioner should approximate the inverse of A. gcrotmk is a ‘flexible’ algorithm and the preconditioner can vary from iteration to iteration. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.
- **callback**: function, optional
  User-supplied function to call after each iteration. It is called as callback(xk), where xk is the current solution vector.
- **m**: int, optional
  Number of inner FGMRES iterations per each outer iteration. Default: 20
- **k**: int, optional
  Number of vectors to carry between inner FGMRES iterations. According to [R26], good values are around m. Default: m
- **CU**: list of tuples, optional
  List of tuples (c, u) which contain the columns of the matrices C and U in the GCROT(m,k) algorithm. For details, see [R26]. The list given and vectors contained in it are modified in-place. If not given, start from empty matrices. The c elements in the tuples can be None, in which case the vectors are recomputed via c = A u on start and orthogonalized as described in [R27].
- **discard_C**: bool, optional
  Discard the C-vectors at the end. Useful if recycling Krylov subspaces for different linear systems.
- **truncate**: {'oldest', 'smallest'}, optional
  Truncation scheme to use. Drop: oldest vectors, or vectors with smallest singular values using the scheme discussed in [1,2]. See [R26] for detailed comparison. Default: ‘oldest’
Returns

- **x**: array or matrix
  - The solution found.
- **info**: int
  - Provides convergence information:
    - **0**: successful exit
    - **>0**: convergence to tolerance not achieved, number of iterations

References

[R25], [R26], [R27]

Iterative methods for least-squares problems:

- `lsqr(A, b[, damp, atol, btol, conlim, ...])` Find the least-squares solution to a large, sparse, linear system of equations.
- `lsmr(A, b[, damp, atol, btol, conlim, ...])` Iterative solver for least-squares problems.

`scipy.sparse.linalg.lsqr(A, b, damp=0.0, atol=1e-08, btol=1e-08, conlim=100000000.0, iter_lim=None, show=False, calc_var=False, x0=None)`

Find the least-squares solution to a large, sparse, linear system of equations.

The function solves \(Ax = b\) or \(\min ||b - Ax||^2\) or \(\min ||Ax - b||^2 + \alpha^2 ||x||^2\).

The matrix A may be square or rectangular (over-determined or under-determined), and may have any rank.

| 1. Unsymmetric equations -- solve \(Ax = b\) |
| 2. Linear least squares -- solve \(Ax = b\) in the least-squares sense |
| 3. Damped least squares -- solve \((A + \alpha I)x = (b + \alpha \beta)\) in the least-squares sense |

Parameters

- **A**: {sparse matrix, ndarray, LinearOperator}
  - Representation of an m-by-n matrix. It is required that the linear operator can produce \(Ax\) and \(A^T x\).
- **b**: array_like, shape (m,)
  - Right-hand side vector b.
- **damp**: float
  - Damping coefficient.
- **atol, btol**: float, optional
  - Stopping tolerances. If both are 1.0e-9 (say), the final residual norm should be accurate to about 9 digits. (The final x will usually have fewer correct digits, depending on \(\text{cond}(A)\) and the size of damp.)
- **conlim**: float, optional
  - Another stopping tolerance. \(\text{lsqr}\) terminates if an estimate of \(\text{cond}(A)\) exceeds \(\text{conlim}\). For compatible systems \(Ax = b\), \(\text{conlim}\) could be as large as 1.0e+12 (say). For least-squares problems, \(\text{conlim}\) should be less than 1.0e+8. Maximum precision can be obtained by setting \(\text{atol} = \text{btol} = \text{conlim} = \text{zero}\), but the number of iterations may then be excessive.
- **iter_lim**: int, optional
  - Explicit limitation on number of iterations (for safety).
- **show**: bool, optional
  - Display an iteration log.
calc_var : bool, optional
    Whether to estimate diagonals of \((A' A + \text{damp}^2 I)^{-1}\).

x0 : array_like, shape (n,), optional
    Initial guess of x, if None zeros are used.
    New in version 1.0.0.

Returns

x : ndarray of float
    The final solution.

istop : int
    Gives the reason for termination. 1 means x is an approximate solution to
    \(Ax = b\). 2 means x approximately solves the least-squares problem.

itn : int
    Iteration number upon termination.

r1norm : float
    \(\|r\|, \text{where } r = b - Ax\).

r2norm : float
    \(\sqrt{\|r\|^2 + \text{damp}^2 \|x\|^2}\). Equal to r1norm
    if damp == 0.

anorm : float
    Estimate of Frobenius norm of \(Abar = [A]; [\text{damp} \times I]\).

acond : float
    Estimate of \(\text{cond}(Abar)\).

arnorm : float
    Estimate of \(\|A'r - \text{damp}^2 x\|\).

xnorm : float
    \(\|x\|\)

var : ndarray of float
    If calc_var is True, estimates all diagonals of \((A' A)^{-1}\) (if damp
    == 0) or more generally \((A' A + \text{damp}^2 I)^{-1}\). This is well de-
    fined if A has full column rank or \(\text{damp} > 0\). (Not sure what var means if
    rank(A) < n and damp = 0.)

Notes

LSQR uses an iterative method to approximate the solution. The number of iterations required to reach a certain
accuracy depends strongly on the scaling of the problem. Poor scaling of the rows or columns of A should
therefore be avoided where possible.

For example, in problem 1 the solution is unaltered by row-scaling. If a row of A is very small or large compared
to the other rows of A, the corresponding row of \((A \ b)\) should be scaled up or down.

In problems 1 and 2, the solution x is easily recovered following column-scaling. Unless better information is
known, the nonzero columns of A should be scaled so that they all have the same Euclidean norm (e.g., 1.0).

In problem 3, there is no freedom to re-scale if damp is nonzero. However, the value of damp should be assigned
only after attention has been paid to the scaling of A.

The parameter damp is intended to help regularize ill-conditioned systems, by preventing the true solution from
being very large. Another aid to regularization is provided by the parameter acond, which may be used to
terminate iterations before the computed solution becomes very large.

If some initial estimate x0 is known and if damp == 0, one could proceed as follows:

1. Compute a residual vector \(r_0 = b - A \times x_0\).
2. Use LSQR to solve the system \(A \times dx = r_0\).
3. Add the correction dx to obtain a final solution \(x = x_0 + dx\).

This requires that x0 be available before and after the call to LSQR. To judge the benefits, suppose LSQR
takes k1 iterations to solve \(A \times x = b\) and k2 iterations to solve \(A \times dx = r_0\). If x0 is “good”, norm(r0) will be
smaller than norm(b). If the same stopping tolerances atol and btol are used for each system, k1 and k2 will be
similar, but the final solution $x_0 + dx$ should be more accurate. The only way to reduce the total work is to use a larger stopping tolerance for the second system. If some value $btol$ is suitable for $A^* x = b$, the larger value $btol*\|b\|/\|r_0\|$ should be suitable for $A^* dx = r_0$.

Preconditioning is another way to reduce the number of iterations. If it is possible to solve a related system $M x = b$ efficiently, where $M$ approximates $A$ in some helpful way (e.g. $M - A$ has low rank or its elements are small relative to those of $A$), LSQR may converge more rapidly on the system $A + M^{-1} z = b$, after which $x$ can be recovered by solving $M x = z$.

If $A$ is symmetric, LSQR should not be used!

Alternatives are the symmetric conjugate-gradient method (cg) and/or SYMMLQ. SYMMLQ is an implementation of symmetric cg that applies to any symmetric $A$ and will converge more rapidly than LSQR. If $A$ is positive definite, there are other implementations of symmetric cg that require slightly less work per iteration than SYMMLQ (but will take the same number of iterations).

References

[R35], [R36], [R37]

Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import lsqr

>>> A = csc_matrix([[1., 0.], [1., 1.], [0., 1.]], dtype=float)

The first example has the trivial solution $[0, 0]$

```python
>>> b = np.array([0., 0., 0.], dtype=float)
>>> x, istop, itn, r1norm = lsqr(A, b)[:4]
The exact solution is $x = 0$
```python
```python
>>> istop
0
>>> x
array([0., 0.])
```

The stopping code $istop=0$ returned indicates that a vector of zeros was found as a solution. The returned solution $x$ indeed contains $[0., 0.]$. The next example has a non-trivial solution:

```python
>>> b = np.array([1., 0., -1.], dtype=float)
>>> x, istop, itn, r1norm = lsqr(A, b)[:4]
```python
```python
>>> istop
1
>>> x
array([1., -1.])
>>> itn
1
>>> r1norm
4.440892098500627e-16
```

As indicated by $istop=1$, $lsqr$ found a solution obeying the tolerance limits. The given solution $[1., -1.]$ obviously solves the equation. The remaining return values include information about the number of iterations ($itn=1$) and the remaining difference of left and right side of the solved equation. The final example demonstrates the behavior in the case where there is no solution for the equation:

```python
>>> b = np.array([1., 0.01, -1.], dtype=float)
>>> x, istop, itn, r1norm = lsqr(A, b)[:4]
```python
```python
>>> istop
2
```

5.21. Sparse matrices (scipy.sparse) 1415
istop indicates that the system is inconsistent and thus x is rather an approximate solution to the corresponding least-squares problem. rlnorm contains the norm of the minimal residual that was found.

scipy.sparse.linalg.lsmr(A, b, damp=0.0, atol=1e-06, btol=1e-06, conlim=100000000.0, maxiter=None, show=False, x0=None)

Iterative solver for least-squares problems.

lsmr solves the system of linear equations $Ax = b$. If the system is inconsistent, it solves the least-squares problem $\min ||b - Ax||_2$. A is a rectangular matrix of dimension $m$-by-$n$, where all cases are allowed: $m = n$, $m > n$, or $m < n$. B is a vector of length $m$. The matrix A may be dense or sparse (usually sparse).

**Parameters**

- **A**: {matrix, sparse matrix, ndarray, LinearOperator}
  
  Matrix A in the linear system.

- **b**: array_like, shape (m,)
  
  Vector b in the linear system.

- **damp**: float
  
  Damping factor for regularized least-squares. `lsmr` solves the regularized least-squares problem:

  \[
  \min \| (b) - (A \times x) \|_2
  \]

  \[
  \| (0) \times (damp \times I) \|_2
  \]

  where damp is a scalar. If damp is None or 0, the system is solved without regularization.

- **atol, btol**: float, optional
  
  Stopping tolerances. `lsmr` continues iterations until a certain backward error estimate is smaller than some quantity depending on atol and btol. Let $r = b - Ax$ be the residual vector for the current approximate solution $x$. If $Ax = b$ seems to be consistent, `lsmr` terminates when $\| r \| = \| b - Ax \| _2 <= atol * \| A \| * \| x \| + btol * \| b \|$. Otherwise, `lsmr` terminates when $\| A^T r \| <= atol * \| A \| * \| r \|$. If both tolerances are 1.0e-6 (say), the final $\| r \|$ should be accurate to about 6 digits. (The final $x$ will usually have fewer correct digits, depending on $\| \text{cond}(A) \|$ and the size of LAMBDA.) If atol or btol is None, a default value of 1.0e-6 will be used. Ideally, they should be estimates of the relative error in the entries of A and B respectively. For example, if the entries of A have 7 correct digits, set atol = 1e-7. This prevents the algorithm from doing unnecessary work beyond the uncertainty of the input data.

- **conlim**: float, optional
  
  `lsmr` terminates if an estimate of $\text{cond}(A)$ exceeds conlim. For compatible systems $Ax = b$, conlim could be as large as 1.0e+12 (say). For least-squares problems, conlim should be less than 1.0e+8. If conlim is None, the default value is 1e+8. Maximum precision can be obtained by setting atol = btol = conlim = 0, but the number of iterations may then be excessive.

- **maxiter**: int, optional
  
  `lsmr` terminates if the number of iterations reaches maxiter. The default is maxiter = min(m, n). For ill-conditioned systems, a larger value of
maxiter may be needed.

show : bool, optional
    Print iterations logs if show=True.

x0 : array_like, shape (n,), optional
    Initial guess of x, if None zeros are used.
    New in version 1.0.0.

Returns
-----
x : ndarray of float
    Least-square solution returned.

istop : int
    istop gives the reason for stopping:

    istop = 0 means x=0 is a solution. If x0 was given, then x=x0 is an approximate solution to A*x=B,
        according to atol and btol.
        = 1 means x is an approximate solution to A*x=B, according to atol.
        = 2 means x approximately solves the least-squares problem
        according to atol.
        = 3 means COND(A) seems to be greater than CONLIM.
        = 4 is the same as 1 with atol = btol = eps (machine precision)
        = 5 is the same as 2 with atol = eps.
        = 6 is the same as 3 with CONLIM = 1/eps.
        = 7 means ITN reached maxiter before the other stopping conditions were satisfied.

itn : int
    Number of iterations used.

normr : float
    norm(b-Ax)

normar : float
    norm(A^T (b - Ax))

norma : float
    norm(A)

conda : float
    Condition number of A.

normx : float
    norm(x)

Notes
New in version 0.11.0.

References
[R33], [R34]

Examples
```python
from scipy.sparse import csc_matrix
from scipy.sparse.linalg import lsmr

A = csc_matrix([[1., 0.], [1., 1.], [0., 1.]], dtype=float)
```

The first example has the trivial solution \([0, 0]\)
```python
b = np.array([0., 0., 0.], dtype=float)
>>> x, istop, itn, normr = lsmr(A, b)[:4]
>>> istop
0
>>> x
array([ 0., 0.])
```

The stopping code \(istop=0\) returned indicates that a vector of zeros was found as a solution. The returned solution \(x\) indeed contains \([0., 0.]\). The next example has a non-trivial solution:
```python
b = np.array([1., 0., -1.], dtype=float)
>>> x, istop, itn, normr = lsmr(A, b)[:4]
>>> istop
1
>>> x
array([ 1., -1.])
>>> itn
1
>>> normr
4.40892098500627e-16
```

As indicated by \(istop=1\), \(lsmr\) found a solution obeying the tolerance limits. The given solution \([1., -1.]\) obviously solves the equation. The remaining return values include information about the number of iterations \((\text{itn}=1)\) and the remaining difference of left and right side of the solved equation. The final example demonstrates the behavior in the case where there is no solution for the equation:
```python
b = np.array([1., 0.01, -1.], dtype=float)
>>> x, istop, itn, normr = lsmr(A, b)[:4]
>>> istop
2
>>> x
array([ 1.00333333, -0.99666667])
>>> A.dot(x)-b
array([ 0.00333333, -0.00333333, 0.00333333])
>>> normr
0.005773502691896255
```

\(istop\) indicates that the system is inconsistent and thus \(x\) is rather an approximate solution to the corresponding least-squares problem. \(normr\) contains the minimal distance that was found.

### Matrix factorizations

**Eigenvalue problems:**

- \(eigs(A[, k, M, sigma, which, v0, ncv, ...])\) Find \(k\) eigenvalues and eigenvectors of the square matrix \(A\).
- \(eigsh(A[, k, M, sigma, which, v0, ncv, ...])\) Find \(k\) eigenvalues and eigenvectors of the real symmetric square matrix or complex hermitian matrix \(A\).
Table 5.195 – continued from previous page

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>lobpcg</code></td>
<td>Locally Optimal Block Preconditioned Conjugate Gradient Method (LOBPCG)</td>
</tr>
</tbody>
</table>

```python
scipy.sparse.linalg.eigs(A, k=6, M=None, sigma=None, which='LM', v0=None, ncv=None, maxiter=None, tol=0, return_eigenvectors=True, Minv=None, OPinv=None, OPpart=None)
```

Find k eigenvalues and eigenvectors of the square matrix A.

Solves $A \cdot x[i] = w[i] \cdot x[i]$, the standard eigenvalue problem for $w[i]$ eigenvalues with corresponding eigenvectors $x[i]$.

If $M$ is specified, solves $A \cdot x[i] = w[i] \cdot M \cdot x[i]$, the generalized eigenvalue problem for $w[i]$ eigenvalues with corresponding eigenvectors $x[i]$.

**Parameters**

- **A**: ndarray, sparse matrix or LinearOperator
  An array, sparse matrix, or LinearOperator representing the operation $A \cdot x$, where $A$ is a real or complex square matrix.

- **k**: int, optional
  The number of eigenvalues and eigenvectors desired. $k$ must be smaller than $N-1$. It is not possible to compute all eigenvectors of a matrix.

- **M**: ndarray, sparse matrix or LinearOperator, optional
  An array, sparse matrix, or LinearOperator representing the operation $M \cdot x$ for the generalized eigenvalue problem $A \cdot x = w \cdot M \cdot x$.
  $M$ must represent a real, symmetric matrix if $A$ is real, and must represent a complex, hermitian matrix if $A$ is complex. For best results, the data type of $M$ should be the same as that of $A$. Additionally:
  - If $sigma$ is None, $M$ is positive definite
  - If $sigma$ is specified, $M$ is positive semi-definite

- **sigma**: real or complex, optional
  Find eigenvalues near $sigma$ using shift-invert mode. This requires an operator to compute the solution of the linear system $[A - sigma \cdot M] \cdot x = b$. This is done internally via a (sparse) LU decomposition for an explicit matrix $M$, or via an iterative solver for a general linear operator. Alternatively, the user can supply the matrix or operator $Minv$, which gives $x = Minv \cdot b = M^{-1} \cdot b$. For a real matrix $A$, shift-invert can either be done in imaginary mode or real mode, specified by the parameter $OPpart$ (‘r’ or ‘i’). Note that when $sigma$ is specified, the keyword ‘which’ (below) refers to the shifted eigenvalues $w'[i]$ where:

  - **If $A$ is real and $OPpart$ == ‘r’ (default),**
    
    $w'[i] = 1/2 \cdot \frac{1}{(w[i]-sigma)} + \frac{1}{(w[i]-\text{conj}(sigma))}.$

  - **If $A$ is real and $OPpart$ == ‘i’,**
    
    $w'[i] = 1/2i \cdot \frac{1}{(w[i]-sigma)} - \frac{1}{(w[i]-\text{conj}(sigma))}.$

  - **If $A$ is complex**, $w'[i] = 1/(w[i]-sigma)$.

- **v0**: ndarray, optional

5.21. Sparse matrices (scipy.sparse)
Find 6 eigenvectors of the identity matrix:

```python
w, v = eigh(A)
```

**Examples**

```python
? eigh
```

**References**

This function is a wrapper to the ARPACK (R18) SNEUPD, DNEUPD, CNELPD, ZNEUPD functions which are described in the ARPACKUsers' Guide.

**Notes**

Similar to the decomposition for a matrix A, eigenvalues and eigenvectors for symmetric matrix A

**Returns**

An array of k eigenvalues.

An array of k eigenvectors. v[:, i] is the eigenvector corresponding to the eigenvalue w[i].

**Raises**

'ArpackNoConvergence'

When the requested convergence is not obtained. The currently converged eigenvalues and eigenvectors can be found as 'eigenvalues' and 'eigenvectors' attributes of the exception object.

**See also:**

eigsh eigenvalues and eigenvectors for symmetric matrix A

svds singular value decomposition for a matrix A

**Examples**

Find 6 eigenvectors of the identity matrix:

```python
w, v = eigh(A)
```

eigsh eigenvalues and eigenvectors for symmetric matrix A

svds singular value decomposition for a matrix A

**Examples**

Find 6 eigenvectors of the identity matrix:

```python
w, v = eigh(A)
```
```python
>>> import scipy.sparse as sparse
>>> id = np.eye(13)
>>> vals, vecs = sparse.linalg.eigs(id, k=6)
>>> vals
array([ 1.+0.j, 1.+0.j, 1.+0.j, 1.+0.j, 1.+0.j, 1.+0.j])
>>> vecs.shape
(13, 6)
```

`scipy.sparse.linalg.eigsh(A, k=6, M=None, sigma=None, which='LM', v0=None, ncv=None, maxiter=None, tol=0, return_eigenvectors=True, Minv=None, OPinv=None, mode='normal')`

Find k eigenvalues and eigenvectors of the real symmetric square matrix or complex hermitian matrix A.

Solves `A * x[i] = w[i] * x[i]`, the standard eigenvalue problem for `w[i]` eigenvalues with corresponding eigenvectors `x[i]`.

If M is specified, solves `A * x[i] = w[i] * M * x[i]`, the generalized eigenvalue problem for `w[i]` eigenvalues with corresponding eigenvectors `x[i]`.

**Parameters**
- `A` : An N x N matrix, array, sparse matrix, or LinearOperator representing the operation `A * x`, where A is a real symmetric matrix. For buckling mode (see below) A must additionally be positive-definite.
- `k` : int, optional
  The number of eigenvalues and eigenvectors desired. `k` must be smaller than N. It is not possible to compute all eigenvectors of a matrix.

**Returns**
- `w` : array
  Array of k eigenvalues
- `v` : array
  An array representing the k eigenvectors. The column `v[:, i]` is the eigenvector corresponding to the eigenvalue `w[i]`.

**Other Parameters**
- `M` : An N x N matrix, array, sparse matrix, or linear operator representing the operation `M * x` for the generalized eigenvalue problem `A * x = w * M * x`.
  M must represent a real, symmetric matrix if A is real, and must represent a complex, hermitian matrix if A is complex. For best results, the data type of M should be the same as that of A. Additionally:
  - If `sigma` is None, M is symmetric positive definite.
  - If `sigma` is specified, M is symmetric positive semi-definite.
  - In buckling mode, M is symmetric indefinite.
  If `sigma` is None, eigsh requires an operator to compute the solution of the linear equation `M * x = b`. This is done internally via a (sparse) LU decomposition for an explicit matrix M, or via an iterative solver for a general linear operator. Alternatively, the user can supply the matrix or operator `Minv`, which gives `x = Minv * b = M^-1 * b`.

- `sigma` : real
  Find eigenvalues near `sigma` using shift-invert mode. This requires an operator to compute the solution of the linear system `(A - sigma * M) x = b`, where M is the identity matrix if unspecified. This is computed internally via a (sparse) LU decomposition for explicit matrices A & M, or via an iterative solver if either A or M is a general linear operator. Alternatively, the user can supply the matrix or operator `OPinv`, which gives `x = OPinv * b = [A - sigma * M]^-1 * b`. Note that when `sigma` is specified, the keyword ‘which’ refers to the shifted eigenvalues `w'[i]` where:
  ```
  if mode == ‘normal’, w'[i] = 1 / (w[i] - sigma).
  ```
```
if mode == 'cayley', w'[i] = (w[i] + sigma) / (w[i] - sigma).
if mode == 'buckling', w'[i] = w[i] / (w[i] - sigma).

(see further discussion in 'mode' below)

v0 : ndarrray, optional
Starting vector for iteration. Default: random

ncv : int, optional
The number of Lanczos vectors generated ncv must be greater than k and smaller than n; it is recommended that ncv > 2*k. Default: min(n, max(2*k + 1, 20))

which : str ['LM' | 'SM' | 'LA' | 'SA' | 'BE']
If A is a complex hermitian matrix, 'BE' is invalid. Which k eigenvectors and eigenvalues to find:

'LM': Largest (in magnitude) eigenvalues
'SM': Smallest (in magnitude) eigenvalues
'LA': Largest (algebraic) eigenvalues
'SA': Smallest (algebraic) eigenvalues
'BE': Half (k/2) from each end of the spectrum

When k is odd, return one more (k/2+1) from the high end. When sigma != None, 'which' refers to the shifted eigenvalues w'[i] (see discussion in 'sigma', above). ARPACK is generally better at finding large values than small values. If small eigenvalues are desired, consider using shift-invert mode for better performance.

maxiter : int, optional
Maximum number of Arnoldi update iterations allowed. Default: n*10

tol : float
Relative accuracy for eigenvalues (stopping criterion). The default value of 0 implies machine precision.

Minv : N x N matrix, array, sparse matrix, or LinearOperator
See notes in M, above

OPinv : N x N matrix, array, sparse matrix, or LinearOperator
See notes in sigma, above.

return_eigenvectors : bool
Return eigenvectors (True) in addition to eigenvalues

mode : string ['normal' | 'buckling' | 'cayley']
Specify strategy to use for shift-invert mode. This argument applies only for real-valued A and sigma != None. For shift-invert mode, ARPACK internally solves the eigenvalue problem OP * x'[i] = w'[i] * B * x'[i] and transforms the resulting Ritz vectors x'[i] and Ritz values w'[i] into the desired eigenvectors of the problem A * x[i] = w[i] * M * x[i]. The modes are as follows:

'cayley': OP = [A - sigma * M]^-1 * [A + sigma * M], B = M, w'[i] = (w[i] + sigma) / (w[i] - sigma)

The choice of mode will affect which eigenvalues are selected by the keyword 'which', and can also impact the stability of convergence (see [2] for a discussion)

Raises ArpackNoConvergence
When the requested convergence is not obtained.
The currently converged eigenvalues and eigenvectors can be found as 
```
eigenvalues and eigenvectors attributes of the exception object.
```

SciPy Reference Guide, Release 1.0.0

```
scipy.sparse.linalg.lobpcg(A, X, B=None, M=None, Y=None, tol=None, maxiter=20, 
largest=True, verbosityLevel=0, retLambdaHistory=False, retResidualNormsHistory=False)
```

Locally Optimal Block Preconditioned Conjugate Gradient Method (LOBPCG)

LOBPCG is a preconditioned eigensolver for large symmetric positive definite ( SPD) generalized eigenproblems.

**Parameters**

A : {sparse matrix, dense matrix, LinearOperator}
The symmetric linear operator of the problem, usually a sparse matrix. Often called the “stiffness matrix”.

X : array_like
    Initial approximation to the k eigenvectors. If A has shape=(n,n) then X should have shape=(n,k).

B : {dense matrix, sparse matrix, LinearOperator}, optional
    the right hand side operator in a generalized eigenproblem. by default, B = Identity often called the “mass matrix”

M : {dense matrix, sparse matrix, LinearOperator}, optional
    preconditioner to A; by default M = Identity M should approximate the inverse of A

Y : array_like, optional
    n-by-sizeY matrix of constraints, sizeY < n The iterations will be performed in the B-orthogonal complement of the column-space of Y. Y must be full rank.

**Returns**

w : array
    Array of k eigenvalues

v : array
    An array of k eigenvectors. V has the same shape as X.

**Other Parameters**

tol : scalar, optional
    Solver tolerance (stopping criterion) by default: tol=n*sqrt(eps)

maxiter : integer, optional

5.21. Sparse matrices (scipy.sparse)
maximum number of iterations by default: maxiter=min(n,20)

largest : bool, optional
when True, solve for the largest eigenvalues, otherwise the smallest

verbosityLevel : integer, optional
controls solver output. default: verbosityLevel = 0.

retLambdaHistory : boolean, optional
whether to return eigenvalue history

retResidualNormsHistory : boolean, optional
whether to return history of residual norms

Notes
If both retLambdaHistory and retResidualNormsHistory are True, the return tuple has the following format
(lambda, V, lambda history, residual norms history).

In the following n denotes the matrix size and m the number of required eigenvalues (smallest or largest).

The LOBPCG code internally solves eigenproblems of the size 3``m`` on every iteration by calling the “standard” dense eigensolver, so if m is not small enough compared to n, it does not make sense to call the LOBPCG code, but rather one should use the “standard” eigensolver, e.g. numpy or scipy function in this case. If one calls the LOBPCG algorithm for 5``m``>`n``, it will most likely break internally, so the code tries to call the standard function instead.

It is not that n should be large for the LOBPCG to work, but rather the ratio n/m should be large. It you call the LOBPCG code with m=1 and n=10, it should work, though n is small. The method is intended for extremely large n/m, see e.g., reference [28] in http://arxiv.org/abs/0705.2626

The convergence speed depends basically on two factors:
1. How well relatively separated the seeking eigenvalues are from the rest of the eigenvalues. One can try to vary m to make this better.
2. How well conditioned the problem is. This can be changed by using proper preconditioning. For example, a rod vibration test problem (under tests directory) is ill-conditioned for large n, so convergence will be slow, unless efficient preconditioning is used. For this specific problem, a good simple preconditioner function would be a linear solve for A, which is easy to code since A is tridiagonal.

Examples
Solve A x = lambda B x with constraints and preconditioning.

```python
>>> from scipy.sparse import spdiags, issparse
>>> from scipy.sparse.linalg import lobpcg, LinearOperator
>>> n = 100
>>> vals = [np.arange(n, dtype=np.float64) + 1]
>>> A = spdiags(vals, 0, n, n)
>>> A.toarray()
array([[ 1.,  0.,  0., ...,  0.,  0.,  0.],
       [ 0.,  2.,  0., ...,  0.,  0.,  0.],
       [ 0.,  0.,  3., ...,  0.,  0.,  0.],
       ...,
       [ 0.,  0.,  0., ..., 98.,  0.,  0.],
       [ 0.,  0.,  0., ...,  0.,  0.,  0.]])
```
Constraints.

```python
>>> Y = np.eye(n, 3)
```

Initial guess for eigenvectors, should have linearly independent columns. Column dimension = number of requested eigenvalues.

```python
>>> X = np.random.rand(n, 3)
```

Preconditioner – inverse of A (as an abstract linear operator).

```python
>>> invA = spdiags([1./vals[0]], 0, n, n)
>>> def precond( x ):
...    return invA * x
>>> M = LinearOperator(matvec=precond, shape=(n, n), dtype=float)
```

Here, invA could of course have been used directly as a preconditioner. Let us then solve the problem:

```python
>>> eigs, vecs = lobpcg(A, X, Y=Y, M=M, tol=1e-4, maxiter=40, largest=False)
>>> eigs
array([ 4., 5., 6.])
```

Note that the vectors passed in Y are the eigenvectors of the 3 smallest eigenvalues. The results returned are orthogonal to those.

Singular values problems:

```python
scipy.sparse.linalg.svds(A[, k, ncv, tol, which, v0, maxiter, ...])
```

Compute the largest k singular values/vectors for a sparse matrix.

**Parameters**

- **A**: [sparse matrix, LinearOperator]
  - Array to compute the SVD on, of shape (M, N)
- **k**: int, optional
  - Number of singular values and vectors to compute. Must be 1 <= k < min(A.shape).
- **ncv**: int, optional
  - The number of Lanczos vectors generated ncv must be greater than k+1 and smaller than n; it is recommended that ncv > 2*k Default: min(n, max(2*k + 1, 20))
- **tol**: float, optional
- **which**: str, ['LM', 'SM'], optional
  - Which k singular values to find:
    - 'LM': largest singular values
    - 'SM': smallest singular values
    - New in version 0.12.0.
- **v0**: ndarray, optional
  - Starting vector for iteration, of length min(A.shape). Should be an approximate left singular vector if N > M and a right singular vector otherwise.
SciPy Reference Guide, Release 1.0.0

Default: random
New in version 0.12.0.

maxiter : int, optional
Maximum number of iterations.
New in version 0.12.0.

return_singular_vectors : bool or str, optional
- True: return singular vectors (True) in addition to singular values.
New in version 0.12.0.
- ‘u’: only return the u matrix, without computing vh (if N > M).
- ‘vh’: only return the vh matrix, without computing u (if N <= M).

Returns

u : ndarray, shape=(M, k)
Unitary matrix having left singular vectors as columns. If return_singular_vectors is “vh”, this variable is not computed, and None is returned instead.
s : ndarray, shape=(k,)
The singular values.
vt : ndarray, shape=(k, N)
Unitary matrix having right singular vectors as rows. If return_singular_vectors is “u”, this variable is not computed, and None is returned instead.

Notes
This is a naive implementation using ARPACK as an eigensolver on A.H * A or A * A.H, depending on which one is more efficient.

Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import svds, eigs
>>> A = csc_matrix([[1, 0, 0], [5, 0, 2], [0, -1, 0], [0, 0, 3]], dtype=float)
>>> u, s, vt = svds(A, k=2)
>>> s
array([ 2.75193379, 5.60596651])
>>> np.sqrt(eigs(A.dot(A.T), k=2)[0]).real
array([ 5.60596651, 2.75193379])
```

Complete or incomplete LU factorizations

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>

</tbody>
</table>

SuperLU
LU factorization of a sparse matrix.

```python
scipy.sparse.linalg.splu(A, permc_spec=None, diag_pivot_thresh=None, relax=None, panel_size=None, options={})
```

Compute the LU decomposition of a sparse, square matrix.

Parameters

- **A**: sparse matrix
  Sparse matrix to factorize. Should be in CSR or CSC format.
- **permc_spec**: str, optional
  How to permute the columns of the matrix for sparsity preservation. (default: ‘COLAMD’)

1426 Chapter 5. API Reference
• NATURAL: natural ordering
  • AMD_ATA: minimum degree ordering on the structure of A^T A
  • AMD_AT_PLUS_A: minimum degree ordering on the structure of A^T+A.
  • COLAMD: approximate minimum degree column ordering

diag_pivot_thresh : float, optional
  Threshold used for a diagonal entry to be an acceptable pivot. See SuperLU user’s guide for details [R43]

relax : int, optional
  Expert option for customizing the degree of relaxing supernodes. See SuperLU user’s guide for details [R43]

panel_size : int, optional
  Expert option for customizing the panel size. See SuperLU user’s guide for details [R43]

options : dict, optional
  Dictionary containing additional expert options to SuperLU. See SuperLU user guide [R43] (section 2.4 on the ‘Options’ argument) for more details. For example, you can specify options=dict(Equil=False, IterRefine='SINGLE')) to turn equilibration off and perform a single iterative refinement.

Returns

invA : scipy.sparse.linalg.SuperLU
  Object, which has a solve method.

See also:

spilu incomplete LU decomposition

Notes

This function uses the SuperLU library.

References

[R43]

Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import spilu

>>> A = csc_matrix([[1., 0., 0.], [5., 0., 2.], [0., -1., 0.]], dtype=float)
>>> B = spilu(A)
>>> x = np.array([1., 2., 3.], dtype=float)
>>> B.solve(x)
array([ 1., -3., -1.5])
>>> A.dot(B.solve(x))
array([ 1., 2., 3.])
>>> B.solve(A.dot(x))
array([ 1., 2., 3.])
```

scipy.sparse.linalg.spilu(A, drop_tol=None, fill_factor=None, drop_rule=None, permc_spec=None, diag_pivot_thresh=None, relax=None, panel_size=None, options=None)

Compute an incomplete LU decomposition for a sparse, square matrix.

The resulting object is an approximation to the inverse of A.

Parameters

A : (N, N) array_like
  Sparse matrix to factorize

drop_tol : float, optional
Drop tolerance (0 <= tol <= 1) for an incomplete LU decomposition. (default: 1e-4)

fill_factor : float, optional
    Specifies the fill ratio upper bound (>= 1.0) for ILU. (default: 10)

drop_rule : str, optional
    Comma-separated string of drop rules to use. Available rules: basic, prows, column, area, secondary, dynamic, interp. (Default: basic, area)
    See SuperLU documentation for details.

Remaining other options

Returns

invA_approx : scipy.sparse.linalg.SuperLU
    Object, which has a solve method.

See also:
splu complete LU decomposition

Notes

To improve the better approximation to the inverse, you may need to increase fill_factor AND decrease drop_tol.

This function uses the SuperLU library.

Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import spilu

>>> A = csc_matrix([[1., 0., 0.], [5., 0., 2.], [0., -1., 0.]], dtype=float)
>>> B = spilu(A)
>>> x = np.array([1., 2., 3.], dtype=float)
>>> B.solve(x)
array([ 1. , -3. , -1.5])
>>> A.dot(B.solve(x))
array([ 1., 2., 3.])
>>> B.solve(A.dot(x))
array([ 1., 2., 3.])
```

class scipy.sparse.linalg.SuperLU

LU factorization of a sparse matrix.

Factorization is represented as:

\[ Pr \times A \times Pc = L \times U \]

To construct these SuperLU objects, call the splu and spilu functions.

Notes

New in version 0.14.0.

Examples

The LU decomposition can be used to solve matrix equations. Consider:

```python
>>> import numpy as np
>>> from scipy.sparse import csc_matrix, linalg as sla

>>> A = csc_matrix([[1,2,0,4],[1,0,0,1],[1,0,2,1],[2,2,1,0]])
```

This can be solved for a given right-hand side:
>>> lu = sla.splu(A)
>>> b = np.array([1, 2, 3, 4])
>>> x = lu.solve(b)
>>> A.dot(x)
array([1., 2., 3., 4.])

The `lu` object also contains an explicit representation of the decomposition. The permutations are represented as mappings of indices:

```python
>>> lu.perm_r
array([0, 2, 1, 3], dtype=int32)
>>> lu.perm_c
array([2, 0, 1, 3], dtype=int32)
```

The L and U factors are sparse matrices in CSC format:

```python
>>> lu.L.A
array([[ 1. , 0. , 0. , 0. ],
       [ 0. , 1. , 0. , 0. ],
       [ 0. , 0. , 1. , 0. ],
       [ 1. , 0.5, 0.5, 1. ]])
>>> lu.U.A
array([[ 2., 0., 1., 4.],
       [ 0., 2., 1., 1.],
       [ 0., 0., 1., 1.],
       [ 0., 0., 0., -5.]])
```

The permutation matrices can be constructed:

```python
>>> Pr = csc_matrix((4, 4))
>>> Pr[lu.perm_r, np.arange(4)] = 1
>>> Pc = csc_matrix((4, 4))
>>> Pc[np.arange(4), lu.perm_c] = 1
```

We can reassemble the original matrix:

```python
>>> (Pr.T * (lu.L * lu.U) * Pc.T).A
array([[ 1., 2., 0., 4.],
       [ 1., 0., 0., 1.],
       [ 1., 0., 2., 1.],
       [ 2., 2., 1., 0.]])
```

### Attributes

- **shape**: Shape of the original matrix as a tuple of ints.
- **nnz**: Number of nonzero elements in the matrix.
- **perm_c**: Permutation `Pc` represented as an array of indices.
- **perm_r**: Permutation `Pr` represented as an array of indices.
- **L**: Lower triangular factor with unit diagonal as a `scipy.sparse.csc_matrix`.
- **U**: Upper triangular factor as a `scipy.sparse.csc_matrix`.

**SuperLU.shape**

Shape of the original matrix as a tuple of ints.
SuperLU.nnz
Number of nonzero elements in the matrix.

SuperLU.perm_c
Permutation Pc represented as an array of indices.

The column permutation matrix can be reconstructed via:

```python
>>> Pc = np.zeros((n, n))
>>> Pc[np.arange(n), perm_c] = 1
```

SuperLU.perm_r
Permutation Pr represented as an array of indices.

The row permutation matrix can be reconstructed via:

```python
>>> Pr = np.zeros((n, n))
>>> Pr[perm_r, np.arange(n)] = 1
```

SuperLU.L
Lower triangular factor with unit diagonal as a `scipy.sparse.csc_matrix`.
New in version 0.14.0.

SuperLU.U
Upper triangular factor as a `scipy.sparse.csc_matrix`.
New in version 0.14.0.

Methods

`solve(rhs[, trans])`
Solves linear system of equations with one or several right-hand sides.

SuperLU.solve(rhs[, trans])
Solves linear system of equations with one or several right-hand sides.

**Parameters**

- `rhs` : ndarray, shape (n,) or (n, k)
  Right hand side(s) of equation
  Type of system to solve:

<table>
<thead>
<tr>
<th>Trans</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>‘N’</td>
<td>$A \times x = \text{rhs}$ (default)</td>
</tr>
<tr>
<td>‘T’</td>
<td>$A^\top \times x = \text{rhs}$</td>
</tr>
<tr>
<td>‘H’</td>
<td>$A^\H \times x = \text{rhs}$</td>
</tr>
</tbody>
</table>

**Returns**

- `x` : ndarray, shape `rhs.shape`
  Solution vector(s)

Exceptions

- `ArpackNoConvergence(msg, eigenvalues, ...)`
  ARPACK iteration did not converge
- `ArpackError(info[, infodict])`
  ARPACK error

**exception**

`scipy.sparse.linalg.ArpackNoConvergence(msg, eigenvalues, eigenvectors)`
ARPACK iteration did not converge

ARPACK error

**Functions**

- `aslinearoperator(A)`
  Return A as a LinearOperator.

- `bicg(A, b[, x0, tol, maxiter, M, callback])`
  Use BIConjugate Gradient iteration to solve $Ax = b$.

- `bicgstab(A, b[, x0, tol, maxiter, M, callback])`
  Use BIConjugate Gradient STABilized iteration to solve $Ax = b$.

- `cg(A, b[, x0, tol, maxiter, M, callback])`
  Use Conjugate Gradient iteration to solve $Ax = b$.

- `cgs(A, b[, x0, tol, maxiter, M, callback])`
  Use Conjugate Gradient Squared iteration to solve $Ax = b$.

- `eigs(A[, k, M, sigma, which, v0, ncv, ...])`
  Find k eigenvalues and eigenvectors of the square matrix A.

- `eigsh(A[, k, M, sigma, which, v0, ncv, ...])`
  Find k eigenvalues and eigenvectors of the real symmetric square matrix or complex hermitian matrix A.

- `expm(A)`
  Compute the matrix exponential using Pade approximation.

- `expm_multiply(A, B[, start, stop, num, endpoint])`
  Compute the action of the matrix exponential of A on B.

- `factorized(A)`
  Return a function for solving a sparse linear system, with A pre-factorized.

- `gcrotmk(A, b[, x0, tol, maxiter, M, ...])`
  Solve a matrix equation using flexible GCROT(m,k) algorithm.

- `gmres(A, b[, x0, tol, restart, maxiter, M, ...])`
  Use Generalized Minimal RESidual iteration to solve $Ax = b$.

- `inv(A)`
  Compute the inverse of a sparse matrix

- `lgmres(A, b[, x0, tol, maxiter, M, ...])`
  Solve a matrix equation using the LGMRES algorithm.

- `lobpcg(A, X[, B, M, Y , tol, maxiter, ...])`
  Locally Optimal Block Preconditioned Conjugate Gradient Method (LOBPCG)

- `lsmr(A, b[, damp, atol, btol, conlim, ...])`
  Iterative solver for least-squares problems.

- `lsqr(A, b[, damp, atol, btol, conlim, ...])`
  Find the least-squares solution to a large, sparse, linear system of equations.

- `minres(A, b[, x0, shift, tol, maxiter, M, ...])`
  Use MINimum RESidual iteration to solve $Ax=b$

- `norm(x[, ord, axis])`
  Norm of a sparse matrix

- `onenormest(A[, t, itmax, compute_v, compute_w])`
  Compute a lower bound of the 1-norm of a sparse matrix.

- `qmr(A, b[, x0, tol, maxiter, M1, M2, callback])`
  Use Quasi-Minimal Residual iteration to solve $Ax = b$.

- `spilu(A[, drop_tol, fill_factor, drop_rule, ...])`
  Compute an incomplete LU decomposition for a sparse, square matrix.

- `splu(A[, perm_spec, diag_pivot_thresh, ...])`
  Compute the LU decomposition of a sparse, square matrix.

- `spsolve(A, b[, perm_spec, use_umfpack])`
  Solve the sparse linear system $Ax=b$, where $b$ may be a vector or a matrix.

- `spsolve_triangular(A, b[, lower, ...])`
  Solve the equation $Ax = b$ for $x$, assuming $A$ is a triangular matrix.

- `svds(A[, k, ncv, tol, which, v0, maxiter, ...])`
  Compute the largest k singular values/vectors for a sparse matrix.

- `use_solver(**kwargs)`
  Select default sparse direct solver to be used.

**Classes**

- `LinearOperator(dtype, shape)`
  Common interface for performing matrix vector products

- `SuperLU()`
  LU factorization of a sparse matrix.

**Exceptions**

5.21. Sparse matrices (scipy.sparse) 1433
Exceptions

`SparseEfficiencyWarning`

`SparseWarning`

5.21.2 Usage information

There are seven available sparse matrix types:

1. `csc_matrix`: Compressed Sparse Column format
2. `csr_matrix`: Compressed Sparse Row format
3. `bsr_matrix`: Block Sparse Row format
4. `lil_matrix`: List of Lists format
5. `dok_matrix`: Dictionary of Keys format
6. `coo_matrix`: COOrdinate format (aka IJV, triplet format)
7. `dia_matrix`: DIAgonal format

To construct a matrix efficiently, use either `dok_matrix` or `lil_matrix`. The `lil_matrix` class supports basic slicing and fancy indexing with a similar syntax to NumPy arrays. As illustrated below, the COO format may also be used to efficiently construct matrices. Despite their similarity to NumPy arrays, it is strongly discouraged to use NumPy functions directly on these matrices because NumPy may not properly convert them for computations, leading to unexpected (and incorrect) results. If you do want to apply a NumPy function to these matrices, first check if SciPy has its own implementation for the given sparse matrix class, or convert the sparse matrix to a NumPy array (e.g. using the `toarray()` method of the class) first before applying the method.

To perform manipulations such as multiplication or inversion, first convert the matrix to either CSC or CSR format. The lil_matrix format is row-based, so conversion to CSR is efficient, whereas conversion to CSC is less so.

All conversions among the CSR, CSC, and COO formats are efficient, linear-time operations.

Matrix vector product

To do a vector product between a sparse matrix and a vector simply use the matrix `dot` method, as described in its docstring:

```
>>> import numpy as np
>>> from scipy.sparse import csr_matrix
>>> A = csr_matrix([[1, 2, 0], [0, 0, 3], [4, 0, 5]])
>>> v = np.array([1, 0, -1])
```
A.dot(v)
array([ 1, -3, -1], dtype=int64)

Warning: As of NumPy 1.7, np.dot is not aware of sparse matrices, therefore using it will result on unexpected results or errors. The corresponding dense array should be obtained first instead:

np.dot(A.toarray(), v)
array([ 1, -3, -1], dtype=int64)
but then all the performance advantages would be lost.

The CSR format is specially suitable for fast matrix vector products.

Example 1

Construct a 1000x1000 lil_matrix and add some values to it:

A = lil_matrix((1000, 1000))
A[0, :100] = rand(100)
A[1, 100:200] = A[0, :100]
A.setdiag(rand(1000))

Now convert it to CSR format and solve A x = b for x:

A = A.tocsr()
b = rand(1000)
x = spsolve(A, b)

Convert it to a dense matrix and solve, and check that the result is the same:

x_ = solve(A.toarray(), b)

Now we can compute norm of the error with:

err = norm(x-x_)
err < 1e-10
True

It should be small :)

Example 2

Construct a matrix in COO format:

I = array([0,3,1,0])
J = array([0,3,1,2])
Notice that the indices do not need to be sorted. Duplicate (i,j) entries are summed when converting to CSR or CSC.

This is useful for constructing finite-element stiffness and mass matrices.

Further Details

CSR column indices are not necessarily sorted. Likewise for CSC row indices. Use the .sorted_indices() and .sort_indices() methods when sorted indices are required (e.g. when passing data to other libraries).

5.22 Sparse linear algebra (scipy.sparse.linalg)

5.22.1 Abstract linear operators

<table>
<thead>
<tr>
<th>LinearOperator(dtype, shape)</th>
<th>Common interface for performing matrix vector products</th>
</tr>
</thead>
<tbody>
<tr>
<td>aslinearoperator(A)</td>
<td>Return A as a LinearOperator.</td>
</tr>
</tbody>
</table>

class scipy.sparse.linalg.LinearOperator (dtype, shape)

Common interface for performing matrix vector products

Many iterative methods (e.g. cg, gmres) do not need to know the individual entries of a matrix to solve a linear system A*x=b. Such solvers only require the computation of matrix vector products, A*v where v is a dense vector. This class serves as an abstract interface between iterative solvers and matrix-like objects.

To construct a concrete LinearOperator, either pass appropriate callables to the constructor of this class, or subclass it.

A subclass must implement either one of the methods _matvec and _matmat, and the attributes/properties shape (pair of integers) and dtype (may be None). It may call the __init__ on this class to have these attributes validated. Implementing _matvec automatically implements _matmat (using a naive algorithm) and vice-versa.

Optionally, a subclass may implement _rmatvec or _adjoint to implement the Hermitian adjoint (conjugate transpose). As with _matvec and _matmat, implementing either _rmatvec or _adjoint implements the other automatically. Implementing _adjoint is preferable; _rmatvec is mostly there for backwards compatibility.

Parameters

- shape : tuple
  Matrix dimensions (M,N).
- matvec : callable f(v)
  Returns returns A * v.
- rmatvec : callable f(v)
  Returns A^H * v, where A^H is the conjugate transpose of A.
- matmat : callable f(V)
Returns $A \ast V$, where $V$ is a dense matrix with dimensions $(N,K)$.

```

dtype : dtype
    Data type of the matrix.
```

See also:

```
aslinearoperator
    Construct LinearOperators
```

Notes

The user-defined matvec() function must properly handle the case where $v$ has shape $(N,)$ as well as the $(N,1)$ case. The shape of the return type is handled internally by LinearOperator.

LinearOperator instances can also be multiplied, added with each other and exponentiated, all lazily: the result of these operations is always a new, composite LinearOperator, that defers linear operations to the original operators and combines the results.

Examples

```
>>> import numpy as np
>>> from scipy.sparse.linalg import LinearOperator
>>> def mv(v):
...     return np.array([2*v[0], 3*v[1]])
...
>>> A = LinearOperator((2,2), matvec=mv)
>>> A
<2x2 _CustomLinearOperator with dtype=float64>
>>> A.matvec(np.ones(2))
array([ 2., 3.])
>>> A * np.ones(2)
array([ 2., 3.])
```

Attributes

```
args
    (tuple) For linear operators describing products etc. of other linear operators, the operands of the binary operation.
```

Methods

```
__call__(x)
adjoint()
    Hermitian adjoint.
dot(x)
    Matrix-matrix or matrix-vector multiplication.
matmat(X)
    Matrix-matrix multiplication.
matvec(x)
    Matrix-vector multiplication.
rmatvec(x)
    Adjoint matrix-vector multiplication.
transpose()
    Transpose this linear operator.
```

LinearOperator.__call__(x)

LinearOperator.adjoint()
    Hermitian adjoint.
    Returns the Hermitian adjoint of self, aka the Hermitian conjugate or Hermitian transpose. For a complex matrix, the Hermitian adjoint is equal to the conjugate transpose.
    Can be abbreviated self.H instead of self.adjoint().

5.22. Sparse linear algebra (scipy.sparse.linalg)
Returns

A_H : LinearOperator
Hermitian adjoint of self.

LinearOperator.dot(x)
Matrix-matrix or matrix-vector multiplication.

Parameters
x : array_like
1-d or 2-d array, representing a vector or matrix.

Returns
Ax : array
1-d or 2-d array (depending on the shape of x) that represents the result of applying this linear operator on x.

LinearOperator.matmat(X)
Matrix-matrix multiplication.

Performs the operation y=A*X where A is an MxN linear operator and X dense N*K matrix or ndarray.

Parameters
X : {matrix, ndarray}
An array with shape (N,K).

Returns
Y : {matrix, ndarray}
A matrix or ndarray with shape (M,K) depending on the type of the X argument.

Notes
This matmat wraps any user-specified matmat routine or overridden _matmat method to ensure that y has the correct type.

LinearOperator.matvec(x)
Matrix-vector multiplication.

Performs the operation y=A*x where A is an MxN linear operator and x is a column vector or 1-d array.

Parameters
x : {matrix, ndarray}
An array with shape (N,) or (N,1).

Returns
y : {matrix, ndarray}
A matrix or ndarray with shape (M,) or (M,1) depending on the type and shape of the x argument.

Notes
This matvec wraps the user-specified matvec routine or overridden _matvec method to ensure that y has the correct shape and type.

LinearOperator.rmatvec(x)
Adjoint matrix-vector multiplication.

Performs the operation y = A^H * x where A is an MxN linear operator and x is a column vector or 1-d array.

Parameters
x : {matrix, ndarray}
An array with shape (M,) or (M,1).

Returns
y : {matrix, ndarray}
A matrix or ndarray with shape (N,) or (N,1) depending on the type and shape of the x argument.

Notes
This rmatvec wraps the user-specified rmatvec routine or overridden _rmatvec method to ensure that y has the correct shape and type.

LinearOperator.transpose()
Transpose this linear operator.
returns a LinearOperator that represents the transpose of this one. Can be abbreviated self.T instead of self.transpose().

```python
scipy.sparse.linalg.aslinearoperator(A)
```

Return A as a LinearOperator.

‘A’ may be any of the following types:

- ndarray
- matrix
- sparse matrix (e.g. csr_matrix, lil_matrix, etc.)
- LinearOperator
- An object with .shape and .matvec attributes

See the LinearOperator documentation for additional information.

**Examples**

```python
>>> from scipy.sparse.linalg import aslinearoperator
>>> M = np.array([[1,2,3],[4,5,6]], dtype=np.int32)
>>> aslinearoperator(M)
<2x3 MatrixLinearOperator with dtype=int32>
```

### 5.22.2 Matrix Operations

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>inv(A)</code></td>
<td>Compute the inverse of a sparse matrix</td>
</tr>
<tr>
<td><code>expm(A)</code></td>
<td>Compute the matrix exponential using Pade approximation.</td>
</tr>
<tr>
<td><code>expm_multiply(A, B[, start, stop, num, endpoint])</code></td>
<td>Compute the action of the matrix exponential of A on B.</td>
</tr>
</tbody>
</table>

#### scipy.sparse.linalg.inv(A)

Compute the inverse of a sparse matrix

**Parameters**
- `A` : (M,M) ndarray or sparse matrix

**Returns**
- `Ainv` : (M,M) ndarray or sparse matrix
  - square matrix to be inverted
  - inverse of A

**Notes**

This computes the sparse inverse of A. If the inverse of A is expected to be non-sparse, it will likely be faster to convert A to dense and use scipy.linalg.inv.

**Examples**

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import inv
>>> A = csc_matrix([[1., 0.], [1., 2.]])
>>> Ainv = inv(A)
>>> Ainv
<2x2 sparse matrix of type '<class 'numpy.float64'>'
  with 3 stored elements in Compressed Sparse Column format>
>>> A.dot(Ainv)
<2x2 sparse matrix of type '<class 'numpy.float64'>'
  with 2 stored elements in Compressed Sparse Column format>
>>> A.dot(Ainv).todense()
matrix([[ 1.,  0.],
         [ 0.,  1.]])
```
New in version 0.12.0.

```python
from scipy.sparse.linalg import expm
```

The matrix exponential is computed using the Pade approximation.

**Parameters**
- `A`: (M,M) array_like or sparse matrix
  - 2D Array or Matrix (sparse or dense) to be exponentiated

**Returns**
- `expA`: (M,M) ndarray
  - Matrix exponential of `A`

**Notes**

This is algorithm (6.1) which is a simplification of algorithm (5.1).

New in version 0.12.0.

**References**

[R373]

**Examples**

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import expm
>>> A = csc_matrix([[1, 0, 0], [0, 2, 0], [0, 0, 3]])
>>> A.todense()
matrix([[1, 0, 0],
        [0, 2, 0],
        [0, 0, 3]], dtype=int64)
>>> Aexp = expm(A)
>>> Aexp
<3x3 sparse matrix of type '<class 'numpy.float64'>'
  with 3 stored elements in Compressed Sparse Column format>
>>> Aexp.todense()
matrix([[ 2.71828183, 0. , 0. ],
        [ 0. , 7.3890561 , 0. ],
        [ 0. , 0. , 20.08553692]])
```

SciPy Reference Guide, Release 1.0.0

New in version 0.12.0.

```python
from scipy.sparse.linalg import expm_multiply
```

The action of the matrix exponential on a matrix or vector is computed.

**Parameters**
- `A`: transposable linear operator
  - The operator whose exponential is of interest.
- `B`: ndarray
  - The matrix or vector to be multiplied by the matrix exponential of `A`.
- `start`: scalar, optional
  - The starting time point of the sequence.
- `stop`: scalar, optional
  - The end time point of the sequence, unless `endpoint` is set to False. In that case, the sequence consists of all but the last of `num + 1` evenly spaced time points, so that `stop` is excluded. Note that the step size changes when `endpoint` is False.
- `num`: int, optional
  - Number of time points to use.
- `endpoint`: bool, optional
  - If True, `stop` is the last time point. Otherwise, it is not included.

**Returns**
- `expm_A_B`: ndarray
  - The result of the action $e^{t \cdot A} B$. 

1440 Chapter 5. API Reference
Notes
The optional arguments defining the sequence of evenly spaced time points are compatible with the arguments of `numpy.linspace`.

The output ndarray shape is somewhat complicated so I explain it here. The ndim of the output could be either 1, 2, or 3. It would be 1 if you are computing the expm action on a single vector at a single time point. It would be 2 if you are computing the expm action on a vector at multiple time points, or if you are computing the expm action on a matrix at a single time point. It would be 3 if you want the action on a matrix with multiple columns at multiple time points. If multiple time points are requested, expm_A_B[0] will always be the action of the expm at the first time point, regardless of whether the action is on a vector or a matrix.

References
[R374], [R375]

Examples
```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import expm, expm_multiply

>>> A = csc_matrix([[1, 0], [0, 1]])
>>> A.todense()
matrix([[1, 0],
        [0, 1]], dtype=int64)

>>> B = np.array([np.exp(-1.), np.exp(-2.)])

>>> expm_multiply(A, B, start=1, stop=2, num=3, endpoint=True)
array([[ 1. ,  0.36787944],
        [ 1.64872127,  0.60653066],
        [ 2.71828183,  1. ]])

>>> expm(A).dot(B)  # Verify 1st timestep
array([ 1. ,  0.36787944])

>>> expm(1.5*A).dot(B)  # Verify 2nd timestep
array( [ 1.64872127,  0.60653066])

>>> expm(2*A).dot(B)  # Verify 3rd timestep
array([ 2.71828183,  1. ])
```

5.22.3 Matrix norms

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>norm(x[, ord, axis])</code></td>
<td>Norm of a sparse matrix</td>
</tr>
<tr>
<td><code>onenormest(A[, t, itmax, compute_v, compute_w])</code></td>
<td>Compute a lower bound of the 1-norm of a sparse matrix.</td>
</tr>
</tbody>
</table>

```python
scipy.sparse.linalg.norm(x, ord=None, axis=None)
```

Norm of a sparse matrix

This function is able to return one of seven different matrix norms, depending on the value of the `ord` parameter.

**Parameters**
- `x`: a sparse matrix
- `ord`: {non-zero int, inf, -inf, ‘fro’}, optional
- `axis`: {int, 2-tuple of ints, None}, optional

If `axis` is an integer, it specifies the axis of `x` along which to compute the vector norms. If `axis` is a 2-tuple, it specifies the axes that hold 2-D matrices, and the matrix norms of these matrices are computed. If `axis` is None then
either a vector norm (when \( x \) is 1-D) or a matrix norm (when \( x \) is 2-D) is returned.

**Returns**

\( n \) : float or ndarray

**Notes**

Some of the ord are not implemented because some associated functions like, _multi_svd_norm, are not yet available for sparse matrix.

This docstring is modified based on numpy.linalg.norm. https://github.com/numpy/numpy/blob/master/numpy/linalg/linalg.py

The following norms can be calculated:

<table>
<thead>
<tr>
<th>ord</th>
<th>norm for sparse matrices</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>Frobenius norm</td>
</tr>
<tr>
<td>‘fro’</td>
<td>Frobenius norm</td>
</tr>
<tr>
<td>inf</td>
<td>max(sum(abs(x), axis=1))</td>
</tr>
<tr>
<td>-inf</td>
<td>min(sum(abs(x), axis=1))</td>
</tr>
<tr>
<td>0</td>
<td>abs(x).sum(axis=axis)</td>
</tr>
<tr>
<td>1</td>
<td>max(sum(abs(x), axis=0))</td>
</tr>
<tr>
<td>-1</td>
<td>min(sum(abs(x), axis=0))</td>
</tr>
<tr>
<td>2</td>
<td>Not implemented</td>
</tr>
<tr>
<td>-2</td>
<td>Not implemented</td>
</tr>
<tr>
<td>other</td>
<td>Not implemented</td>
</tr>
</tbody>
</table>

The Frobenius norm is given by \([R389]\):

\[
||A||_F = \left[ \sum_{i,j} \text{abs}(a_{i,j})^2 \right]^{1/2}
\]

**References**

\([R389]\)

**Examples**

```python
>>> from scipy.sparse import *
>>> import numpy as np
>>> from scipy.sparse.linalg import norm

>>> a = np.arange(9) - 4
>>> a
array([-4, -3, -2, -1,  0,  1,  2,  3,  4])
>>> b = a.reshape((3, 3))
>>> b
array([[-4, -3, -2],
       [-1,  0,  1],
       [ 2,  3,  4]])

>>> b = csr_matrix(b)
>>> norm(b)
7.745966692414834
>>> norm(b, 'fro')
7.745966692414834
>>> norm(b, np.inf)
9
>>> norm(b, -np.inf)
2
>>> norm(b, 1)
7
```
scipy.sparse.linalg.onenormest (A, t=2, itmax=5, compute_v=False, compute_w=False)
Compute a lower bound of the 1-norm of a sparse matrix.

Parameters
A : ndarray or other linear operator
A linear operator that can be transposed and that can produce matrix products.

  t : int, optional
A positive parameter controlling the tradeoff between accuracy versus time and memory usage. Larger values take longer and use more memory but give more accurate output.

  itmax : int, optional
Use at most this many iterations.

  compute_v : bool, optional
Request a norm-maximizing linear operator input vector if True.

  compute_w : bool, optional
Request a norm-maximizing linear operator output vector if True.

Returns
est : float
An underestimate of the 1-norm of the sparse matrix.

  v : ndarray, optional
The vector such that ||Av||_1 == est*||v||_1. It can be thought of as an input to the linear operator that gives an output with particularly large norm.

  w : ndarray, optional
The vector Av which has relatively large 1-norm. It can be thought of as an output of the linear operator that is relatively large in norm compared to the input.

Notes
This is algorithm 2.4 of [1].

In [2] it is described as follows. “This algorithm typically requires the evaluation of about 4t matrix-vector products and almost invariably produces a norm estimate (which is, in fact, a lower bound on the norm) correct to within a factor 3.”

New in version 0.13.0.

[R390], [R391]

Examples
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import onenormest
>>> A = csc_matrix([[1., 0., 0.], [5., 8., 2.], [0., -1., 0.]], dtype=float)
>>> A.todense()
matrix([[ 1., 0., 0.],
        [ 5., 8., 2.],
        [ 0., -1., 0.]])
>>> onenormest(A)
9.0
>>> np.linalg.norm(A.todense(), ord=1)
9.0
5.22.4 Solving linear problems

Direct methods for linear equation systems:

- **spsolve**(A, b[, permc_spec, use_umfpack])
  Solve the sparse linear system \( Ax=b \), where \( b \) may be a vector or a matrix.

- **spsolve_triangular**(A, b[, lower, ...])
  Solve the equation \( A x = b \) for \( x \), assuming \( A \) is a triangular matrix.

- **factorized**(A)
  Return a function for solving a sparse linear system, with \( A \) pre-factorized.

- **MatrixRankWarning**
  Use solver (**kwargs)
  Select default sparse direct solver to be used.

**scipy.sparse.linalg.spsolve**(A, b, permc_spec=None, use_umfpack=True)
Solve the sparse linear system \( Ax=b \), where \( b \) may be a vector or a matrix.

**Parameters**
- A : ndarray or sparse matrix
  The square matrix \( A \) will be converted into CSC or CSR form.
- b : ndarray or sparse matrix
  The matrix or vector representing the right hand side of the equation. If a vector, \( b.shape \) must be \((n,)\) or \((n, 1)\).
- permc_spec : str, optional
  How to permute the columns of the matrix for sparsity preservation. (default: ‘COLAMD’)
  - NATURAL: natural ordering.
  - MMD_ATA: minimum degree ordering on the structure of \( A^T A \)
  - MMD_AT_PLUS_A: minimum degree ordering on the structure of \( A^T + A \)
  - COLAMD: approximate minimum degree column ordering
- use_umfpack : bool, optional
  if True (default) then use umfpack for the solution. This is only referenced if \( b \) is a vector and scikit-umfpack is installed.

**Returns**
- x : ndarray or sparse matrix
  the solution of the sparse linear equation. If \( b \) is a vector, then \( x \) is a vector of size \( A.shape[1] \) If \( b \) is a matrix, then \( x \) is a matrix of size \((A.shape[1], b.shape[1])\)

**Notes**

For solving the matrix expression \( AX = B \), this solver assumes the resulting matrix \( X \) is sparse, as is often the case for very sparse inputs. If the resulting \( X \) is dense, the construction of this sparse result will be relatively expensive. In that case, consider converting \( A \) to a dense matrix and using scipy.linalg.solve or its variants.

**Examples**

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import spsolve
>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
>>> B = csc_matrix([[2, 0], [-1, 0], [2, 0]], dtype=float)
>>> x = spsolve(A, B)
>>> np.allclose(A.dot(x).todense(), B.todense())
True
```

**scipy.sparse.linalg.spsolve_triangular**(A, b, lower=True, overwrite_A=False, overwrite_b=False)
Solve the equation \( A x = b \) for \( x \), assuming \( A \) is a triangular matrix.
scipy.sparse.linalg.factorized(A)

Return a function for solving a sparse linear system, with A pre-factorized.

Parameters

A : (N, N) array_like

Input.

Returns

solve : callable

To solve the linear system of equations given in A, the solve callable should be passed an ndarray of shape (N,).

Examples

```python
>>> from scipy.sparse.linalg import factorized
>>> A = np.array([[ 3. ,  2. , -1. ],
...                [ 2. , -2. ,  4. ],
...                [-1. ,  0.5, -1. ]])
>>> solve = factorized(A) # Makes LU decomposition.
>>> rhsl = np.array([1, -2, 0])
>>> solve(rhsl) # Uses the LU factors.
array([ 1., -2., -2.])
```
Select default sparse direct solver to be used.

**Parameters**

- **useUmfpack**: bool, optional
  Use UMFPACK over SuperLU. Has effect only if scikits.umfpack is installed. Default: True

- **assumeSortedIndices**: bool, optional
  Allow UMFPACK to skip the step of sorting indices for a CSR/CSC matrix. Has effect only if useUmfpack is True and scikits.umfpack is installed. Default: False

**Notes**

The default sparse solver is umfpack when available (scikits.umfpack is installed). This can be changed by passing useUmfpack = False, which then causes the always present SuperLU based solver to be used.

Umfpack requires a CSR/CSC matrix to have sorted column/row indices. If sure that the matrix fulfills this, pass assumeSortedIndices=True to gain some speed.

### Iterative methods for linear equation systems:

- **bicg**
  Use BIConjugate Gradient iteration to solve $Ax = b$.

- **bicgstab**
  Use BIConjugate Gradient STABilized iteration to solve $Ax = b$.

- **cg**
  Use Conjugate Gradient iteration to solve $Ax = b$.

- **cgs**
  Use Conjugate Gradient Squared iteration to solve $Ax = b$.

- **gmres**
  Use Generalized Minimal RESidual iteration to solve $Ax = b$.

- **lgmres**
  Solve a matrix equation using the LGMRES algorithm.

- **minres**
  Use MINimum RESidual iteration to solve $Ax = b$.

- **qmr**
  Use Quasi-Minimal Residual iteration to solve $Ax = b$.

- **gcrotmk**
  Solve a matrix equation using flexible GCROT(m,k) algorithm.

### scipy.sparse.linalg.bicg

Use BIConjugate Gradient iteration to solve $Ax = b$.

**Parameters**

- **A**: {sparse matrix, dense matrix, LinearOperator}
  The real or complex N-by-N matrix of the linear system. It is required that the linear operator can produce $Ax$ and $A^T x$.

- **b**: {array, matrix}
  Right hand side of the linear system. Has shape (N,) or (N,1).

**Returns**

- **x**: {array, matrix}
  The converged solution.

**info**: integer

*Provides convergence information:*

- 0: successful exit
- >0: convergence to tolerance not achieved, number of iterations
- <0: illegal input or breakdown

**Other Parameters**

- **x0**: {array, matrix}
  Starting guess for the solution.

- **tol**: float
  Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below tol.

- **maxiter**: integer
Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.

**M** : {sparse matrix, dense matrix, LinearOperator}

Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.

**callback** : function

User-supplied function to call after each iteration. It is called as callback(xk), where xk is the current solution vector.

```python
scipy.sparse.linalg.bicgstab(A, b, x0=None, tol=1e-05, maxiter=None, M=None, callback=None)
```

Use BIConjugate Gradient STABilized iteration to solve $A x = b$.

**Parameters**

- **A** : {sparse matrix, dense matrix, LinearOperator}
  
  The real or complex N-by-N matrix of the linear system.

- **b** : {array, matrix}
  
  Right hand side of the linear system. Has shape (N,) or (N,1).

**Returns**

- **x** : {array, matrix}
  
  The converged solution.

- **info** : integer

  Provides convergence information:

  - 0 : successful exit
  - >0 : convergence to tolerance not achieved, number of iterations <0 : illegal input or breakdown

**Other Parameters**

- **x0** : {array, matrix}
  
  Starting guess for the solution.

- **tol** : float
  
  Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below tol.

- **maxiter** : integer
  
  Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.

- **M** : {sparse matrix, dense matrix, LinearOperator}
  
  Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.

- **callback** : function
  
  User-supplied function to call after each iteration. It is called as callback(xk), where xk is the current solution vector.

```python
scipy.sparse.linalg.cg(A, b, x0=None, tol=1e-05, maxiter=None, M=None, callback=None)
```

Use Conjugate Gradient iteration to solve $A x = b$.

**Parameters**

- **A** : {sparse matrix, dense matrix, LinearOperator}
  
  The real or complex N-by-N matrix of the linear system. $A$ must represent a hermitian, positive definite matrix.

- **b** : {array, matrix}
  
  Right hand side of the linear system. Has shape (N,) or (N,1).

**Returns**

- **x** : {array, matrix}
  
  The converged solution.

- **info** : integer

  Provides convergence information:

  - 0 : successful exit
  - >0 : convergence to tolerance not
Other Parameters

**x0**: {array, matrix}
Starting guess for the solution.

**tol**: float
Tolerance to achieve. The algorithm terminates when either the relative or
the absolute residual is below *tol*.

**maxiter**: integer
Maximum number of iterations. Iteration will stop after maxiter steps even
if the specified tolerance has not been achieved.

**M**: {sparse matrix, dense matrix, LinearOperator}
Preconditioner for A. The preconditioner should approximate the inverse
of A. Effective preconditioning dramatically improves the rate of conver-
genence, which implies that fewer iterations are needed to reach a given error
tolerance.

**callback**: function
User-supplied function to call after each iteration. It is called as call-
back(xk), where xk is the current solution vector.

```python
scipy.sparse.linalg.cg
```
(A, b, x0=None, tol=1e-05, maxiter=None, M=None, callback=None)

Use Conjugate Gradient Squared iteration to solve $Ax = b$.

**Parameters**

**A**: {sparse matrix, dense matrix, LinearOperator}
The real-valued N-by-N matrix of the linear system.

**b**: {array, matrix}
Right hand side of the linear system. Has shape (N,) or (N,1).

**Returns**

**x**: {array, matrix}
The converged solution.

**info**: integer
Provides convergence information:
0 : successful exit >0 : convergence to tolerance not
achieved, number of iterations <0 : illegal input or break-
down

```python
scipy.sparse.linalg.gmres
```
(A, b, x0=None, tol=1e-05, restart=None, maxiter=None, M=None, callback=None)

Use Generalized Minimal RESidual iteration to solve $Ax = b$.

**Parameters**

**A**: {sparse matrix, dense matrix, LinearOperator}
The real or complex N-by-N matrix of the linear system.
b : {array, matrix}

Right hand side of the linear system. Has shape (N,) or (N,1).

Returns

x : {array, matrix}
The converged solution.

info : int

Provides convergence information:

• 0 : successful exit
• >0 : convergence to tolerance not achieved, number of iterations
• <0 : illegal input or breakdown

Other Parameters

x0 : {array, matrix}
Starting guess for the solution (a vector of zeros by default).

tol : float
Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below tol.

restart : int, optional
Number of iterations between restarts. Larger values increase iteration cost, but may be necessary for convergence. Default is 20.

maxiter : int, optional
Maximum number of iterations (restart cycles). Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.

M : {sparse matrix, dense matrix, LinearOperator}
Inverse of the preconditioner of A. M should approximate the inverse of A and be easy to solve for (see Notes). Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance. By default, no preconditioner is used.

callback : function
User-supplied function to call after each iteration. It is called as callback(rk), where rk is the current residual vector.

restrt : int, optional
DEPRECATED - use restart instead.

See also:

LinearOperator

Notes

A preconditioner, P, is chosen such that P is close to A but easy to solve for. The preconditioner parameter required by this routine is M = P^-1. The inverse should preferably not be calculated explicitly. Rather, use the following template to produce M:

```python
# Construct a linear operator that computes P^-1 * x.
import scipy.sparse.linalg as spla
M_x = lambda x: spla.spsolve(P, x)
M = spla.LinearOperator((n, n), M_x)
```

Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import gmres
>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
>>> b = np.array([2, 4, -1], dtype=float)
>>> x, exitCode = gmres(A, b)
```
scipy.sparse.linalg.lgmres \((A, b, x0=None, tol=1e-05, maxiter=1000, M=None, callback=None, inner_m=30, outer_k=3, outer_v=None, store_outer_Av=True, prepend_outer_v=False)\)

Solve a matrix equation using the LGMRES algorithm.

The LGMRES algorithm \([R379]\); \([R380]\) is designed to avoid some problems in the convergence in restarted GMRES, and often converges in fewer iterations.

### Parameters

- **A**: {sparse matrix, dense matrix, LinearOperator}
  - The real or complex N-by-N matrix of the linear system.
- **b**: {array, matrix}
  - Right hand side of the linear system. Has shape (N,) or (N,1).
- **x0**: {array, matrix}
  - Starting guess for the solution.
- **tol**: float, optional
  - Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below tol.
- **maxiter**: int, optional
  - Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.
- **M**: {sparse matrix, dense matrix, LinearOperator}, optional
  - Preconditioner for A. The preconditioner should approximate the inverse of A. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.
- **callback**: function, optional
  - User-supplied function to call after each iteration. It is called as callback(xk), where xk is the current solution vector.
- **inner_m**: int, optional
  - Number of inner GMRES iterations per each outer iteration.
- **outer_k**: int, optional
  - Number of vectors to carry between inner GMRES iterations. According to \([R379]\), good values are in the range of 1...3. However, note that if you want to use the additional vectors to accelerate solving multiple similar problems, larger values may be beneficial.
- **outer_v**: list of tuples, optional
  - List containing tuples \((v, Av)\) of vectors and corresponding matrix-vector products, used to augment the Krylov subspace, and carried between inner GMRES iterations. The element \(Av\) can be None if the matrix-vector product should be re-evaluated. This parameter is modified in-place by lgmres, and can be used to pass “guess” vectors in and out of the algorithm when solving similar problems.
- **store_outer_Av**: bool, optional
  - Whether LGMRES should store also A*v in addition to vectors v in the outer_v list. Default is True.
- **prepend_outer_v**: bool, optional
  - Whether to put outer_v augmentation vectors before Krylov iterates. In standard LGMRES, prepend_outer_v=False.

### Returns

- **x**: array or matrix
  - The converged solution.
info : int

Provides convergence information:

* 0 : successful exit
* >0 : convergence to tolerance not achieved, number of iterations
* <0 : illegal input or breakdown

Notes
The LGMRES algorithm [R379] [R380] is designed to avoid the slowing of convergence in restarted GMRES, due to alternating residual vectors. Typically, it often outperforms GMRES(m) of comparable memory requirements by some measure, or at least is not much worse.

Another advantage in this algorithm is that you can supply it with ‘guess’ vectors in the outer_v argument that augment the Krylov subspace. If the solution lies close to the span of these vectors, the algorithm converges faster. This can be useful if several very similar matrices need to be inverted one after another, such as in Newton-Krylov iteration where the Jacobian matrix often changes little in the nonlinear steps.

Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import lgmres

>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
>>> b = np.array([2, 4, -1], dtype=float)

>>> x, exitCode = lgmres(A, b)

>>> print(exitCode)  # 0 indicates successful convergence
0

>>> np.allclose(A.dot(x), b)
True
```

scipy.sparse.linalg.minres (A, b, x0=None, shift=0.0, tol=1e-05, maxiter=None, M=None, callback=None, show=False, check=False)

Use MINimum RESidual iteration to solve Ax = b

MINRES minimizes norm(A*x - b) for a real symmetric matrix A. Unlike the Conjugate Gradient method, A can be indefinite or singular.

If shift != 0 then the method solves (A - shift*I)x = b

Parameters

- A : {sparse matrix, dense matrix, LinearOperator}
  The real symmetric N-by-N matrix of the linear system
- b : {array, matrix}
  Right hand side of the linear system. Has shape (N,) or (N,1).
- x0 : {array, matrix}
  The converged solution.

Returns

- x : {array, matrix}
  The converged solution.
- info : integer
  Provides convergence information:
  
  0 : successful exit 
  >0 : convergence to tolerance not achieved, number of iterations 
  <0 : illegal input or breakdown

Other Parameters

- x0 : {array, matrix}
  Starting guess for the solution.
- tol : float
  Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below tol.
maxiter : integer
Maximum number of iterations. Iteration will stop after maxiter steps even
if the specified tolerance has not been achieved.

M : {sparse matrix, dense matrix, LinearOperator}
Preconditioner for A. The preconditioner should approximate the inverse
of A. Effective preconditioning dramatically improves the rate of conver-
gence, which implies that fewer iterations are needed to reach a given error
tolerance.

callback : function
User-supplied function to call after each iteration. It is called as call-
back(xk), where xk is the current solution vector.

Notes
THIS FUNCTION IS EXPERIMENTAL AND SUBJECT TO CHANGE!

scipy.sparse.linalg.qmr(A, b, x0=None, tol=1e-05, maxiter=None, M1=None, M2=None, cal-
back=None)

Use Quasi-Minimal Residual iteration to solve \( Ax = b \).

Parameters
A : {sparse matrix, dense matrix, LinearOperator}
The real-valued N-by-N matrix of the linear system. It is required that the
linear operator can produce \( Ax \) and \( A^T x \).

b : {array, matrix}
Right hand side of the linear system. Has shape (N,) or (N,1).

Returns
x : {array, matrix}
The converged solution.

info : integer
Provides convergence information:
0 : successful exit >0 : convergence to tolerance not
achieved, number of iterations <0 : illegal input or break-
down

Other Parameters
x0 : {array, matrix}
Starting guess for the solution.

tol : float
Tolerance to achieve. The algorithm terminates when either the relative or
the absolute residual is below tol.

maxiter : integer
Maximum number of iterations. Iteration will stop after maxiter steps even
if the specified tolerance has not been achieved.

M1 : {sparse matrix, dense matrix, LinearOperator}
Left preconditioner for A.

M2 : {sparse matrix, dense matrix, LinearOperator}
Right preconditioner for A. Used together with the left preconditioner M1.
The matrix \( M1*A*M2 \) should have better conditioned than A alone.

callback : function
User-supplied function to call after each iteration. It is called as call-
back(xk), where xk is the current solution vector.

LinearOperator

Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import qmr

>>> A = csc_matrix([[3, 2, 0], [1, -1, 0], [0, 5, 1]], dtype=float)
>>> b = np.array([2, 4, -1], dtype=float)
>>> x, exitCode = qmr(A, b)
>>> print(exitCode)  # 0 indicates successful convergence
0
>>> np.allclose(A.dot(x), b)
True
```

scipy.sparse.linalg.gcrotmk (A, b, x0=None, tol=1e-05, maxiter=1000, M=None, callback=None, m=20, k=None, CU=None, discard_C=False, truncate='oldest')

Solve a matrix equation using flexible GCROT(m,k) algorithm.

**Parameters**

- **A**: {sparse matrix, dense matrix, LinearOperator}
  The real or complex N-by-N matrix of the linear system.
- **b**: {array, matrix}
  Right hand side of the linear system. Has shape (N,) or (N,1).
- **x0**: {array, matrix}
  Starting guess for the solution.
- **tol**: float, optional
  Tolerance to achieve. The algorithm terminates when either the relative or the absolute residual is below tol.
- **maxiter**: int, optional
  Maximum number of iterations. Iteration will stop after maxiter steps even if the specified tolerance has not been achieved.
- **M**: {sparse matrix, dense matrix, LinearOperator}, optional
  Preconditioner for A. The preconditioner should approximate the inverse of A. gcrotmk is a ‘flexible’ algorithm and the preconditioner can vary from iteration to iteration. Effective preconditioning dramatically improves the rate of convergence, which implies that fewer iterations are needed to reach a given error tolerance.
- **callback**: function, optional
  User-supplied function to call after each iteration. It is called as callback(xk), where xk is the current solution vector.
- **m**: int, optional
  Number of inner FGMRES iterations per each outer iteration. Default: 20
- **k**: int, optional
  Number of vectors to carry between inner FGMRES iterations. According to [R377], good values are around m. Default: m
- **CU**: list of tuples, optional
  List of tuples (c, u) which contain the columns of the matrices C and U in the GCROT(m,k) algorithm. For details, see [R377]. The list given and vectors contained in it are modified in-place. If not given, start from empty matrices. The c elements in the tuples can be None, in which case the vectors are recomputed via c = A u on start and orthogonalized as described in [R378].
- **discard_C**: bool, optional
  Discard the C-vectors at the end. Useful if recycling Krylov subspaces for different linear systems.
**truncate** : {'oldest', 'smallest'}, optional

Truncation scheme to use. Drop: oldest vectors, or vectors with smallest singular values using the scheme discussed in [1,2]. See [R377] for detailed comparison. Default: ‘oldest’

**Returns**

x : array or matrix

The solution found.

info : int

Provides convergence information:

- 0: successful exit
- >0: convergence to tolerance not achieved, number of iterations

[R376], [R377], [R378]

Iterative methods for least-squares problems:

lsqr(A, b[, damp, atol, btol, conlim, ...]) Find the least-squares solution to a large, sparse, linear system of equations.

lsmr(A, b[, damp, atol, btol, conlim, ...]) Iterative solver for least-squares problems.

scipy.sparse.linalg.lsqr(A, b[, damp=0.0, atol=1e-08, btol=1e-08, conlim=100000000.0, iter_lim=None, show=False, calc_var=False, x0=None]) Find the least-squares solution to a large, sparse, linear system of equations.

The function solves $Ax = b$ or $\min ||b - Ax||^2$ or $\min ||Ax - b||^2 + d^2 ||x||^2$.

The matrix A may be square or rectangular (over-determined or under-determined), and may have any rank.

| 1. Unsymmetric equations -- solve $A\cdot x = b$ |
| 2. Linear least squares -- solve $A\cdot x = b$ in the least-squares sense |
| 3. Damped least squares -- solve $(A + d\cdot I)\cdot x = (b + d\cdot 0)$ in the least-squares sense |

**Parameters**

A : [sparse matrix, ndarray, LinearOperator]

Representation of an m-by-n matrix. It is required that the linear operator can produce $A\cdot x$ and $A^T \cdot x$.

b : array_like, shape (m,)

Right-hand side side vector b.

damp : float

Damping coefficient.

atol, btol : float, optional

Stopping tolerances. If both are 1.0e-9 (say), the final residual norm should be accurate to about 9 digits. (The final x will usually have fewer correct digits, depending on $\text{cond}(A)$ and the size of damp.)

conlim : float, optional

Another stopping tolerance. lsqr terminates if an estimate of $\text{cond}(A)$ exceeds conlim. For compatible systems $A\cdot x = b$, conlim could be as large as 1.0e+12 (say). For least-squares problems, conlim should be less than 1.0e+8. Maximum precision can be obtained by setting atol = btol = conlim = zero, but the number of iterations may then be excessive.

iter_lim : int, optional
Explicit limitation on number of iterations (for safety).

**show** : bool, optional
Display an iteration log.

**calc_var** : bool, optional
Whether to estimate diagonals of \((A'A + \text{damp}^2I)^{-1}\).

**x0** : array_like, shape (n,), optional
Initial guess of x, if None zeros are used.

**Returns**

- **x** : ndarray of float
  The final solution.

- **istop** : int
  Gives the reason for termination. 1 means x is an approximate solution to \(Ax = b\). 2 means x approximately solves the least-squares problem.

- **itn** : int
  Iteration number upon termination.

- **r1norm** : float
  \(\|r\|\), where \(r = b - Ax\).

- **r2norm** : float
  \(\sqrt{\|r\|^2 + \text{damp}^2\|x\|^2}\). Equal to r1norm if \(\text{damp} = 0\).

- **anorm** : float
  Estimate of Frobenius norm of \(\text{Abar} = [A]; [\text{damp}I]\).

- **acond** : float
  Estimate of \(\text{cond}(\text{Abar})\).

- **arnorm** : float
  Estimate of \(\|\text{A}'r - \text{damp}^2x\|\).

- **xnorm** : float
  \(\|x\|\)

- **var** : ndarray of float
  If calc_var is True, estimates all diagonals of \((A'A)^{-1}\) (if damp == 0) or more generally \((A'A + \text{damp}^2I)^{-1}\). This is well defined if A has full column rank or damp > 0. (Not sure what var means if rank(A) < n and damp = 0.)

**Notes**

LSQR uses an iterative method to approximate the solution. The number of iterations required to reach a certain accuracy depends strongly on the scaling of the problem. Poor scaling of the rows or columns of A should therefore be avoided where possible.

For example, in problem 1 the solution is unaltered by row-scaling. If a row of A is very small or large compared to the other rows of A, the corresponding row of (A b) should be scaled up or down.

In problems 1 and 2, the solution x is easily recovered following column-scaling. Unless better information is known, the nonzero columns of A should be scaled so that they all have the same Euclidean norm (e.g., 1.0).

In problem 3, there is no freedom to re-scale if damp is nonzero. However, the value of damp should be assigned only after attention has been paid to the scaling of A.

The parameter damp is intended to help regularize ill-conditioned systems, by preventing the true solution from being very large. Another aid to regularization is provided by the parameter acond, which may be used to terminate iterations before the computed solution becomes very large.

If some initial estimate x0 is known and if damp == 0, one could proceed as follows:
1. Compute a residual vector \(r0 = b - A\times0\).
2. Use LSQR to solve the system \(A\times dx = r0\).
3. Add the correction dx to obtain a final solution \(x = x0 + dx\).
This requires that \( x_0 \) be available before and after the call to LSQR. To judge the benefits, suppose LSQR takes \( k_1 \) iterations to solve \( A^*x = b \) and \( k_2 \) iterations to solve \( A^*dx = r_0 \). If \( x_0 \) is “good”, \( \text{norm}(r_0) \) will be smaller than \( \text{norm}(b) \). If the same stopping tolerances \( \text{atol} \) and \( \text{btol} \) are used for each system, \( k_1 \) and \( k_2 \) will be similar, but the final solution \( x_0 + dx \) should be more accurate. The only way to reduce the total work is to use a larger stopping tolerance for the second system. If some value \( \text{btol} \) is suitable for \( A^*x = b \), the larger value \( \text{btol} \times \text{norm}(b) / \text{norm}(r_0) \) should be suitable for \( A^*dx = r_0 \).

Preconditioning is another way to reduce the number of iterations. If it is possible to solve a related system \( M * x = b \) efficiently, where \( M \) approximates \( A \) in some helpful way (e.g. \( M - A \) has low rank or its elements are small relative to those of \( A \)), LSQR may converge more rapidly on the system \( A^*M(\text{inverse}) * z = b \), after which \( x \) can be recovered by solving \( M * x = z \).

If \( A \) is symmetric, LSQR should not be used!

Alternatives are the symmetric conjugate-gradient method (cg) and/or SYMMLQ. SYMMLQ is an implementation of symmetric cg that applies to any symmetric \( A \) and will converge more rapidly than LSQR. If \( A \) is positive definite, there are other implementations of symmetric cg that require slightly less work per iteration than SYMMLQ (but will take the same number of iterations).

References
[R386], [R387], [R388]

Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import lsqr
>>> A = csc_matrix([[1., 0.], [1., 1.], [0., 1.]], dtype=float)

The first example has the trivial solution \([0, 0]\)

```n
def main()
    >>> b = np.array([0., 0., 0.], dtype=float)
    >>> x, istop, itn, normr = lsqr(A, b)[:4]
    >>> istop
    0
    >>> x
    array([ 0., 0.])

The stopping code \( \text{istop}=0 \) returned indicates that a vector of zeros was found as a solution. The returned solution \( x \) indeed contains \([0, 0]\). The next example has a non-trivial solution:

```n
def main()
    >>> b = np.array([1., 0., -1.], dtype=float)
    >>> x, istop, itn, rnorm = lsqr(A, b)[:4]
    >>> istop
    1
    >>> x
    array([ 1., -1.])
    >>> itn
    1
    >>> rnorm
    4.40892098500627e-16

As indicated by \( \text{istop}=1 \), lsqr found a solution obeying the tolerance limits. The given solution \([1., -1.]\) obviously solves the equation. The remaining return values include information about the number of iterations \( \text{itn}=1 \) and the remaining difference of left and right side of the solved equation. The final example demonstrates the behavior in the case where there is no solution for the equation:

```
>>> b = np.array([1., 0.01, -1.], dtype=float)
>>> x, istop, itn, r1norm = lsimr(A, b)[:4]
>>> istop
2
>>> x
array([ 1.00333333, -0.99666667])
>>> A.dot(x)-b
array([ 0.00333333, -0.00333333, 0.00333333])
>>> r1norm
0.005773502691896255

*istop* indicates that the system is inconsistent and thus *x* is rather an approximate solution to the corresponding least-squares problem. *r1norm* contains the norm of the minimal residual that was found.

**scipy.sparse.linalg.lsmr** *(A, b, damp=0.0, atol=1e-06, btol=1e-06, conlim=100000000.0, maxiter=None, show=False, x0=None)*

Iterative solver for least-squares problems.

lsmr solves the system of linear equations *Ax = b*. If the system is inconsistent, it solves the least-squares problem \( \min ||b - Ax||_2 \). *A* is a rectangular matrix of dimension *m*-by-*n*, where all cases are allowed: *m* = *n*, *m* > *n*, or *m* < *n*. *B* is a vector of length *m*. The matrix *A* may be dense or sparse (usually sparse).

**Parameters**

- **A**: {matrix, sparse matrix, ndarray, LinearOperator}
  Matrix *A* in the linear system.
- **b**: array_like, shape (*m,*)
  Vector *b* in the linear system.
- **damp**: float
  Damping factor for regularized least-squares. *lsqr* solves the regularized least-squares problem:

\[
\min ||(b) - ( Ax )x||_2
\]

where *damp* is a scalar. If *damp* is None or 0, the system is solved without regularization.

- **atol, btol**: float, optional
  Stopping tolerances. *lsqr* continues iterations until a certain backward error estimate is smaller than some quantity depending on atol and btol. Let \( r = b - Ax \) be the residual vector for the current approximate solution *x*. If \( Ax = b \) seems to be consistent, *lsqr* terminates when \( \text{norm}(r) \leq \text{atol} \times \text{norm}(A) \times \text{norm}(x) + \text{btol} \times \text{norm}(b) \). Otherwise, *lsqr* terminates when \( \text{norm}(A^T r) \leq \text{atol} \times \text{norm}(A) + \text{norm}(r) \). If both tolerances are 1.0e-6 (say), the final \( \text{norm}(r) \) should be accurate to about 6 digits. (The final *x* will usually have fewer correct digits, depending on \( \text{cond}(A) \) and the size of LAMBDA.) If *atol* or *btol* is None, a default value of 1.0e-6 will be used. Ideally, they should be estimates of the relative error in the entries of *A* and *B* respectively. For example, if the entries of *A* have 7 correct digits, set atol = 1e-7. This prevents the algorithm from doing unnecessary work beyond the uncertainty of the input data.

- **conlim**: float, optional
  *lsqr* terminates if an estimate of \( \text{cond}(A) \) exceeds *conlim*. For compatible systems \( Ax = b \), *conlim* could be as large as 1.0e+12 (say). For least-squares problems, *conlim* should be less than 1.0e+8. If *conlim* is None, the default value is 1e+8. Maximum precision can be obtained by setting atol = btol = conlim = 0, but the number of iterations may then be excessive.

5.22. Sparse linear algebra (**scipy.sparse.linalg**) 1457
maxiter : int, optional
    *lsmr* terminates if the number of iterations reaches *maxiter*. The default is
    maxiter = min(m, n). For ill-conditioned systems, a larger value of
    *maxiter* may be needed.

show : bool, optional
    Print iterations logs if show=True.

x0 : array_like, shape (n,), optional
    Initial guess of x, if None zeros are used.
    New in version 1.0.0.

Returns

x : ndarray of float
    Least-square solution returned.

istop : int
    istop gives the reason for stopping:

    istop = 0 means x=0 is a solution. If x0 was given, then x=x0 is a
    solution.
    = 1 means x is an approximate solution to A*x = B,
    according to atol and btol.
    = 2 means x approximately solves the least-squares problem
    according to atol.
    = 3 means COND(A) seems to be greater than CONLIM.
    = 4 is the same as 1 with atol = btol = eps,
    (machine precision)
    = 5 is the same as 2 with atol = eps.
    = 6 is the same as 3 with CONLIM = 1/eps.
    = 7 means ITN reached maxiter before the other
    stopping conditions were satisfied.

itn : int
    Number of iterations used.

normr : float
    norm(b-Ax)

normx : float
    norm(x)

Notes

New in version 0.11.0.

References

[R384], [R385]
Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import lsmr

>>> A = csc_matrix([[1., 0.], [1., 1.], [0., 1.]], dtype=float)
The first example has the trivial solution [0, 0]

>>> b = np.array([0., 0., 0.], dtype=float)
>>> x, istop, itn, normr = lsmr(A, b)[:4]
>>> istop
0
>>> x
array([ 0., 0.])

The stopping code istop=0 returned indicates that a vector of zeros was found as a solution. The returned solution x indeed contains [0., 0.]. The next example has a non-trivial solution:

>>> b = np.array([1., 0., -1.], dtype=float)
>>> x, istop, itn, normr = lsmr(A, b)[:4]
>>> istop
1
>>> x
array([ 1., -1.])
>>> itn
1
>>> normr
4.40892098500627e-16

As indicated by istop=1, lsmr found a solution obeying the tolerance limits. The given solution [1., -1.] obviously solves the equation. The remaining return values include information about the number of iterations (itn=1) and the remaining difference of left and right side of the solved equation. The final example demonstrates the behavior in the case where there is no solution for the equation:

>>> b = np.array([1., 0.01, -1.], dtype=float)
>>> x, istop, itn, normr = lsmr(A, b)[:4]
>>> istop
2
>>> x
array([ 1.00333333, -0.99666667])
>>> A.dot(x)-b
array([ 0.00333333, -0.00333333, 0.00333333])
>>> normr
0.005773502691896255

istop indicates that the system is inconsistent and thus x is rather an approximate solution to the corresponding least-squares problem. normr contains the minimal distance that was found.

5.22.5 Matrix factorizations

Eigenvalue problems:

eigs(A[, k, M, sigma, which, v0, ncv, ...]) Find k eigenvalues and eigenvectors of the square matrix A.
Table 5.212 – continued from previous page

`scipy.sparse.linalg.eigs(A, k=6, M=None, sigma=None, which='LM', v0=None, ncv=None, maxiter=None, tol=0, return_eigenvalues=True, Minv=None, OPinv=None, OPpart=None)`

Find k eigenvalues and eigenvectors of the square matrix A.

Solves $A \times [i] = w[i] \times [i]$, the standard eigenvalue problem for $w[i]$ eigenvalues with corresponding eigenvectors $x[i]$.

If $M$ is specified, solves $A \times [i] = w[i] \times M \times [i]$, the generalized eigenvalue problem for $w[i]$ eigenvalues with corresponding eigenvectors $x[i]$

**Parameters**

- **A**: ndarray, sparse matrix or LinearOperator
  - An array, sparse matrix, or LinearOperator representing the operation $A \times x$, where $A$ is a real or complex square matrix.
- **k**: int, optional
  - The number of eigenvalues and eigenvectors desired. $k$ must be smaller than $N-1$. It is not possible to compute all eigenvectors of a matrix.
- **M**: ndarray, sparse matrix or LinearOperator, optional
  - An array, sparse matrix, or LinearOperator representing the operation $M \times x$ for the generalized eigenvalue problem $A \times x = w \times M \times x$.
  - $M$ must represent a real, symmetric matrix if $A$ is real, and must represent a complex, hermitian matrix if $A$ is complex. For best results, the data type of $M$ should be the same as that of $A$. Additionally:
    - If $sigma$ is None, $M$ is positive definite
    - If $sigma$ is specified, $M$ is positive semi-definite
  - If $sigma$ is None, eigs requires an operator to compute the solution of the linear equation $M \times x = b$. This is done internally via a (sparse) LU decomposition for an explicit matrix $M$, or via an iterative solver for a general linear operator. Alternatively, the user can supply the matrix or operator $Minv$, which gives $x = Minv \times b = M^{-1} \times b$.
- **sigma**: real or complex, optional
  - Find eigenvalues near $sigma$ using shift-invert mode. This requires an operator to compute the solution of the linear system $[A - sigma \times M] \times x = b$, where $M$ is the identity matrix if unspecified. This is computed internally via a (sparse) LU decomposition for explicit matrices $A \& M$, or via an iterative solver if either $A$ or $M$ is a general linear operator. Alternatively, the user can supply the matrix or operator $OPinv$, which gives $x = OPinv \times b = [A - sigma \times M]^{-1} \times b$. For a real matrix $A$, shift-invert can either be done in imaginary mode or real mode, specified by the parameter $OPpart$ (‘r’ or ‘i’). Note that when $sigma$ is specified, the keyword ‘which’ (below) refers to the shifted eigenvalues $w'[i]$ where:

  **If $A$ is real and $OPpart == ‘r’ (default),**
  $$w'[i] = 1/2 \times [1/(w[i]-sigma) + 1/(w[i]-conj(sigma))].$$

  **If $A$ is real and $OPpart == ‘i’,**
  $$w'[i] = 1/2i \times [1/(w[i]-sigma) - 1/(w[i]-conj(sigma))].$$
If A is complex, \( w'[i] = 1/(w[i]-\sigma) \).

**v0** : ndarray, optional
Starting vector for iteration. Default: random

**ncv** : int, optional
The number of Lanczos vectors generated \( ncv \) must be greater than \( k \); it is recommended that \( ncv > 2*k \). Default: \( \min(n, \max(2*k + 1, 20)) \)

**which** : str, ['LM', 'SM', 'LR', 'SR', 'LI', 'SI'], optional
Which \( k \) eigenvectors and eigenvalues to find:
- 'LM': largest magnitude
- 'SM': smallest magnitude
- 'LR': largest real part
- 'SR': smallest real part
- 'LI': largest imaginary part
- 'SI': smallest imaginary part

When \( \sigma \neq \text{None} \), 'which' refers to the shifted eigenvalues \( w'[i] \) (see discussion in 'sigma', above). ARPACK is generally better at finding large values than small values. If small eigenvalues are desired, consider using shift-invert mode for better performance.

**maxiter** : int, optional
Maximum number of Arnoldi update iterations allowed Default: \( n*10 \)

**tol** : float, optional
Relative accuracy for eigenvalues (stopping criterion) The default value of 0 implies machine precision.

**return_eigenvectors** : bool, optional
Return eigenvectors (True) in addition to eigenvalues

**M** : ndarray, sparse matrix or LinearOperator, optional
See notes in \( \sigma \), above.

**OP** : ndarray, sparse matrix or LinearOperator, optional
See notes in \( \sigma \), above.

**OPpart** : {'r' or 'i'}, optional
See notes in \( \sigma \), above

**Returns**

**w** : ndarray
Array of \( k \) eigenvalues.

**v** : ndarray
An array of \( k \) eigenvectors. \( v[:, i] \) is the eigenvector corresponding to the eigenvalue \( w[i] \).

**Raises**

**ArpackNoConvergence**
When the requested convergence is not obtained. The currently converged eigenvalues and eigenvectors can be found as eigenvalues and eigenvectors attributes of the exception object.

**See also:**

- **eigsh**
  eigenvalues and eigenvectors for symmetric matrix \( A \)
- **svds**
  singular value decomposition for a matrix \( A \)

**Notes**

This function is a wrapper to the ARPACK [R369] SNEUPD, DNEUPD, CNEUPD, ZNEUPD, functions which use the Implicitly Restarted Arnoldi Method to find the eigenvalues and eigenvectors [R370].

**References**

[R369], [R370]
Examples

Find 6 eigenvectors of the identity matrix:

```python
>>> import scipy.sparse as sparse
>>> id = np.eye(13)
>>> vals, vecs = sparse.linalg.eigs(id, k=6)
>>> vals
array([ 1.+0.j, 1.+0.j, 1.+0.j, 1.+0.j, 1.+0.j, 1.+0.j])
>>> vecs.shape
(13, 6)
```

scipy.sparse.linalg.eigsh(A, k=6, M=None, sigma=None, which='LM', v0=None, ncv=None,
maxiter=None, tol=0, return_eigenvectors=True, Minv=None,
OPinv=None, mode='normal')

Find k eigenvalues and eigenvectors of the real symmetric square matrix or complex hermitian matrix A.

Solves $A \times x[i] = w[i] \times x[i]$, the standard eigenvalue problem for $w[i]$ eigenvalues with corresponding eigenvectors $x[i]$

If M is specified, solves $A \times x[i] = w[i] \times M \times x[i]$, the generalized eigenvalue problem for $w[i]$ eigenvalues with corresponding eigenvectors $x[i]$

Parameters

- **A**: An N x N matrix, array, sparse matrix, or LinearOperator representing the operation $A \times x$, where $A$ is a real symmetric matrix For buckling mode (see below) $A$ must additionally be positive-definite
- **k**: int, optional
  The number of eigenvalues and eigenvectors desired. $k$ must be smaller than N. It is not possible to compute all eigenvalues of a matrix.

Returns

- **w**: array
  Array of k eigenvalues
- **v**: array
  An array representing the k eigenvectors. The column $v[:, i]$ is the eigenvector corresponding to the eigenvalue $w[i]$.

Other Parameters

- **M**: An N x N matrix, array, sparse matrix, or linear operator representing the operation $M \times x$ for the generalized eigenvalue problem $A \times x = w \times M \times x$.
  M must represent a real, symmetric matrix if A is real, and must represent a complex, hermitian matrix if A is complex. For best results, the data type of M should be the same as that of A. Additionally:
  - If sigma is None, M is symmetric positive definite
  - If sigma is specified, M is symmetric positive semi-definite
  In buckling mode, M is symmetric indefinite.

If sigma is None, eigsh requires an operator to compute the solution of the linear equation $M \times x = b$. This is done internally via a (sparse) LU decomposition for an explicit matrix M, or via an iterative solver for a general linear operator. Alternatively, the user can supply the matrix or operator Minv, which gives $x = Minv \times b = M^{-1} \times b$.

- **sigma**: real
  Find eigenvalues near sigma using shift-invert mode. This requires an operator to compute the solution of the linear system $(A - sigma \times M) x = h$, where M is the identity matrix if unspecified. This is computed internally via a (sparse) LU decomposition for explicit matrices A & M, or via an iterative solver if either A or M is a general linear operator. Alternatively, the user can supply the matrix or operator OPinv, which gives $x = OPinv \times b = [A - sigma \times M]^{-1} \times b$. Note that when sigma is specified, the keyword ‘which’ refers to the shifted eigenvalues $w'[i]$ where:

1462 Chapter 5. API Reference
if mode == 'normal', \[ w'[i] = 1 / (w[i] - \text{sigma}) \].

if mode == 'cayley', \[ w'[i] = (w[i] + \text{sigma}) / (w[i] - \text{sigma}) \].

if mode == 'buckling', \[ w'[i] = w[i] / (w[i] - \text{sigma}) \].

(see further discussion in 'mode' below)

\( \text{v0} \): ndarray, optional
Starting vector for iteration. Default: random

\( \text{ncv} \): int, optional
The number of Lanczos vectors generated \( \text{ncv} \) must be greater than \( k \) and smaller than \( n \); it is recommended that \( \text{ncv} > 2k \). Default: \( \min(n, \max(2k + 1, 20)) \)

\( \text{which} \): str ['LM' | 'SM' | 'LA' | 'SA' | 'BE']
If \( A \) is a complex hermitian matrix, ‘BE’ is invalid. Which \( k \) eigenvectors and eigenvalues to find:

‘LM’: Largest (in magnitude) eigenvalues
‘SM’: Smallest (in magnitude) eigenvalues
‘LA’: Largest (algebraic) eigenvalues
‘SA’: Smallest (algebraic) eigenvalues
‘BE’: Half (k/2) from each end of the spectrum

When \( k \) is odd, return one more (k/2+1) from the high end. When \( \text{sigma} \neq \) None, ‘which’ refers to the shifted eigenvalues \( w'[i] \) (see discussion in ‘sigma’, above). ARPACK is generally better at finding large values than small values. If small eigenvalues are desired, consider using shift-invert mode for better performance.

\( \text{maxiter} \): int, optional
Maximum number of Arnoldi update iterations allowed Default: \( n\times10 \)

\( \text{tol} \): float
Relative accuracy for eigenvalues (stopping criterion). The default value of 0 implies machine precision.

\( \text{Minv} \): N x N matrix, array, sparse matrix, or LinearOperator
See notes in M, above

\( \text{OPinv} \): N x N matrix, array, sparse matrix, or LinearOperator
See notes in sigma, above.

\( \text{return_eigenvectors} \): bool
Return eigenvectors (True) in addition to eigenvalues

\( \text{mode} \): string ['normal' | 'buckling' | 'cayley']
Specify strategy to use for shift-invert mode. This argument applies only for real-valued \( A \) and \( \text{sigma} \neq \) None. For shift-invert mode, ARPACK internally solves the eigenvalue problem \( OP \times x'[i] = w'[i] \times B \times x'[i] \) and transforms the resulting Ritz vectors \( x'[i] \) and Ritz values \( w'[i] \) into the desired eigenvectors and eigenvalues of the problem \( A \times x[i] = w[i] \times M \times x[i] \).

The modes are as follows:

‘normal’:
\[
OP = [A - \text{sigma} \times M]^{-1} \times M, \quad B = M, \quad w'[i] = 1 / (w[i] - \text{sigma})
\]

‘buckling’:
\[
OP = [A - \text{sigma} \times M]^{-1} \times A, \quad B = A, \quad w'[i] = w[i] / (w[i] - \text{sigma})
\]

‘cayley’:
\[
OP = [A - \text{sigma} \times M]^{-1} \times [A + \text{sigma} \times M], \quad B = M, \quad w'[i] = (w[i] + \text{sigma}) / (w[i] - \text{sigma})
\]

The choice of mode will affect which eigenvalues are selected by the keyword ‘which’, and can also impact the stability of convergence (see [2] for a discussion).

\( \text{Raises} \) ArpackNoConvergence
SciPy Reference Guide, Release 1.0.0

When the requested convergence is not obtained.
The currently converged eigenvalues and eigenvectors can be found as
`eigenvalues` and `eigenvectors` attributes of the exception object.

See also:
- `eigs` eigenvalues and eigenvectors for a general (nonsymmetric) matrix A
- `svds` singular value decomposition for a matrix A

Notes
This function is a wrapper to the ARPACK [R371] SSEUPD and DSEUPD functions which use the Implicitly
Restarted Lanczos Method to find the eigenvalues and eigenvectors [R372].

References

Examples

```python
>>> import scipy.sparse as sparse
>>> id = np.eye(13)
>>> vals, vecs = sparse.linalg.eigsh(id, k=6)
>>> vals
array([ 1.+0.j, 1.+0.j, 1.+0.j, 1.+0.j, 1.+0.j, 1.+0.j])
>>> vecs.shape
(13, 6)
```

`scipy.sparse.linalg.lobpcg`(A, X, B=None, M=None, Y=None, tol=None, maxiter=20, largest=True, verbosityLevel=0, retLambdaHistory=False, retResidualNormsHistory=False)

Locally Optimal Block Preconditioned Conjugate Gradient Method (LOBPCG)

LOBPCG is a preconditioned eigensolver for large symmetric positive definite (SPD) generalized eigenproblems.

Parameters

- **A**: {sparse matrix, dense matrix, LinearOperator}
  The symmetric linear operator of the problem, usually a sparse matrix. Often
called the “stiffness matrix”.
- **X**: array_like
  Initial approximation to the k eigenvectors. If A has shape=(n,n) then X
  should have shape shape=(n,k).
- **B**: {dense matrix, sparse matrix, LinearOperator}, optional
  the right hand side operator in a generalized eigenproblem. by default, B =
  Identity often called the “mass matrix”
- **M**: {dense matrix, sparse matrix, LinearOperator}, optional
  preconditioner to A; by default M = Identity M should approximate the
  inverse of A
- **Y**: array_like, optional
  n-by-sizeY matrix of constraints, sizeY < n The iterations will be performed
  in the B-orthogonal complement of the column-space of Y. Y must be full
  rank.

Returns

- **w**: array
  Array of k eigenvalues
- **v**: array
  An array of k eigenvectors. V has the same shape as X.

Other Parameters

- **tol**: scalar, optional
  Solver tolerance (stopping criterion) by default: tol=n*sqrt(eps)
SciPy Reference Guide, Release 1.0.0

maxiter : integer, optional
    maximum number of iterations by default: maxiter=min(n,20)

largest : bool, optional
    when True, solve for the largest eigenvalues, otherwise the smallest

verbosityLevel : integer, optional
    controls solver output. default: verbosityLevel = 0.

retLambdaHistory : boolean, optional
    whether to return eigenvalue history

retResidualNormsHistory : boolean, optional
    whether to return history of residual norms

Notes

If both retLambdaHistory and retResidualNormsHistory are True, the return tuple has the following format
(lambdax, V, lambda history, residual norms history).

In the following n denotes the matrix size and m the number of required eigenvalues (smallest or largest).

The LOBPCG code internally solves eigenproblems of the size 3*m on every iteration by calling the “standard”
dense eigensolver, so if m is not small enough compared to n, it does not make sense to call the LOBPCG
code, but rather one should use the “standard” eigensolver, e.g. numpy or scipy function in this case. If one
calls the LOBPCG algorithm for 5*m>n, it will most likely break internally, so the code tries to call the
standard function instead.

It is not that n should be large for the LOBPCG to work, but rather the ratio n/m should be large. If you call the
LOBPCG code with m=1 and n=10, it should work, though n is small. The method is intended for extremely large
n/m, see e.g., reference [28] in http://arxiv.org/abs/0705.2626

The convergence speed depends basically on two factors:

1. How well relatively separated the seeking eigenvalues are from the rest of the eigenvalues. One can try to
   vary m to make this better.

2. How well conditioned the problem is. This can be changed by using proper preconditioning. For example,
a rod vibration test problem (under tests directory) is ill-conditioned for large n, so convergence will be
slow, unless efficient preconditioning is used. For this specific problem, a good simple preconditioner
function would be a linear solve for A, which is easy to code since A is tridiagonal.

Acknowledgements

lobpcg.py code was written by Robert Cimrman. Many thanks belong to Andrew Knyazev, the author of the
algorithm, for lots of advice and support.

References

[R381], [R382], [R383]

Examples

Solve A x = lambda B x with constraints and preconditioning.

```python
>>> from scipy.sparse import spdiags, issparse
>>> from scipy.sparse.linalg import lobpcg, LinearOperator

>>> n = 100
>>> vals = [np.arange(n, dtype=np.float64) + 1]
>>> A = spdiags(vals, 0, n, n)
>>> A.toarray()
array([[ 1., 0., 0., ..., 0., 0., 0.],
       [ 0., 2., 0., ..., 0., 0., 0.],
       [ 0., 0., 3., ..., 0., 0., 0.],
       ...,
       [ 0., 0., 0., ..., 98., 0., 0.],
       [ 0., 0., 0., ..., 0., 0., 0.],
       [ 0., 0., 0., ..., 0., 0., 0.]], dtype=float64)
```
Constraints.

```python
>>> Y = np.eye(n, 3)
```

Initial guess for eigenvectors, should have linearly independent columns. Column dimension = number of requested eigenvalues.

```python
>>> X = np.random.rand(n, 3)
```

Preconditioner – inverse of A (as an abstract linear operator).

```python
>>> invA = spdiags([1./vals[0]], 0, n, n)
>>> def precond( x ):
...     return invA * x
>>> M = LinearOperator(matvec=precond, shape=(n, n), dtype=float)
```

Here, `invA` could of course have been used directly as a preconditioner. Let us then solve the problem:

```python
>>> eigs, vecs = lobpcg(A, X, Y=Y, M=M, tol=1e-4, maxiter=40, largest=False)
>>> eigs
array([ 4., 5., 6.])
```

Note that the vectors passed in Y are the eigenvectors of the 3 smallest eigenvalues. The results returned are orthogonal to those.

Singular values problems:

```python
dev(A[, k, ncv, tol, which, v0, maxiter, ...]) Compute the largest k singular values/vectors for a sparse
scipy.sparse.linalg.svds(A, k=6, ncv=None, tol=0, which='LM', v0=None, maxiter=None, return_singular_vectors=True) Compute the largest k singular values/vectors for a sparse matrix.
```

Parameters

- `A` : [sparse matrix, LinearOperator]
  - Array to compute the SVD on, of shape (M, N)
- `k` : int, optional
  - Number of singular values and vectors to compute. Must be 1 <= k < min(A.shape).
- `ncv` : int, optional
  - The number of Lanczos vectors generated ncv must be greater than k+1 and smaller than n; it is recommended that ncv > 2*k Default: min(n, max(2*k + 1, 20))
- `tol` : float, optional
- `which` : str, ['LM', 'SM'], optional
  - Which k singular values to find:
    - 'LM' : largest singular values
    - 'SM' : smallest singular values
  - New in version 0.12.0.
- `v0` : ndarray, optional
  - Starting vector for iteration, of length min(A.shape). Should be an (approximate) left singular vector if N > M and a right singular vector otherwise.
Default: random
New in version 0.12.0.

maxiter : int, optional
Maximum number of iterations.
New in version 0.12.0.

return_singular_vectors : bool or str, optional
• True: return singular vectors (True) in addition to singular values.
New in version 0.12.0.
• “u”: only return the u matrix, without computing vh (if N > M).
• “vh”: only return the vh matrix, without computing u (if N <= M).

Returns

u : ndarray, shape=(M, k)
Unitary matrix having left singular vectors as columns. If return_singular_vectors is “vh”, this variable is not computed, and None is returned instead.
s : ndarray, shape=(k,)
The singular values.
vt : ndarray, shape=(k, N)
Unitary matrix having right singular vectors as rows. If return_singular_vectors is “u”, this variable is not computed, and None is returned instead.

Notes
This is a naive implementation using ARPACK as an eigensolver on A.H * A or A * A.H, depending on which one is more efficient.

Examples

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import svds, eigs

>>> A = csc_matrix([[1, 0, 0], [5, 0, 2], [0, -1, 0], [0, 0, 3]], dtype=float)

>>> u, s, vt = svds(A, k=2)

>>> s
array([ 2.75193379, 5.60596651])

>>> np.sqrt(eigs(A.dot(A.T), k=2)[0]).real
array([ 5.60596651, 2.75193379])
```

Complete or incomplete LU factorizations

- **splu(A[, permc_spec, diag_pivot_thresh, ...])** : Compute the LU decomposition of a sparse, square matrix.
- **spilu(A[, drop_tol, fill_factor, drop_rule, ...])** : Compute an incomplete LU decomposition for a sparse, square matrix.

**SuperLU**
LU factorization of a sparse matrix.

```python
scipy.sparse.linalg.splu(A, permc_spec=None, diag_pivot_thresh=None, relax=None, panel_size=None, options={})
```
Compute the LU decomposition of a sparse, square matrix.

**Parameters**
- A : sparse matrix
  Sparse matrix to factorize. Should be in CSR or CSC format.
- permc_spec : str, optional
  How to permute the columns of the matrix for sparsity preservation. (default: ‘COLAMD’)
scipy.sparse.linalg.spilu(A, drop_tol=None, fill_factor=None, drop_rule=None, permc_spec=None, diag_pivot_thresh=None, relax=None, panel_size=None, options=None)

Compute an incomplete LU decomposition for a sparse, square matrix.

The resulting object is an approximation to the inverse of A.

Parameters

A : (N, N) array_like
Sparse matrix to factorize

drop_tol : float, optional
Drop tolerance (0 <= tol <= 1) for an incomplete LU decomposition. (default: 1e-4)

**fill_factor**: float, optional

Specifies the fill ratio upper bound (>= 1.0) for ILU. (default: 10)

**drop_rule**: str, optional

Comma-separated string of drop rules to use. Available rules: basic, prows, column, area, secondary, dynamic, interp. (Default: basic, area)

See SuperLU documentation for details.

**Remaining other options**

**Returns**

- **invA_approx**: scipy.sparse.linalg.SuperLU

  Object, which has a solve method.

See also:

- **splu**

  complete LU decomposition

**Notes**

To improve the better approximation to the inverse, you may need to increase fill_factor AND decrease drop_tol.

This function uses the SuperLU library.

**Examples**

```python
>>> from scipy.sparse import csc_matrix
>>> from scipy.sparse.linalg import spilu

>>> A = csc_matrix([[1., 0., 0.], [5., 0., 2.], [0., -1., 0.]], dtype=float)
>>> B = spilu(A)
>>> x = np.array([1., 2., 3.], dtype=float)
>>> B.solve(x)
array([ 1. , -3. , -1.5])

>>> A.dot(B.solve(x))
array([ 1., 2., 3.])

>>> B.solve(A.dot(x))
array([ 1., 2., 3.])
```

**class** scipy.sparse.linalg.SuperLU

LU factorization of a sparse matrix.

Factorization is represented as:

\[ P_r \times A \times P_c = L \times U \]

To construct these `SuperLU` objects, call the `splu` and `spilu` functions.

**Notes**

New in version 0.14.0.

**Examples**

The LU decomposition can be used to solve matrix equations. Consider:

```python
>>> import numpy as np
>>> from scipy.sparse import csc_matrix, linalg as sla

>>> A = csc_matrix([[1,2,0,4],[1,0,0,1],[1,0,2,1],[2,2,1,0]])
```

This can be solved for a given right-hand side:
SciPy Reference Guide, Release 1.0.0

```python
>>> lu = sla.splu(A)
>>> b = np.array([1, 2, 3, 4])
>>> x = lu.solve(b)
>>> A.dot(x)
aarray([ 1., 2., 3., 4.])

The `lu` object also contains an explicit representation of the decomposition. The permutations are represented as mappings of indices:

```python
>>> lu.perm_r
array([0, 2, 1, 3], dtype=int32)

```python
>>> lu.perm_c
array([2, 0, 1, 3], dtype=int32)
```

The L and U factors are sparse matrices in CSC format:

```python
>>> lu.L.A
array([[ 1. , 0. , 0. , 0. ],
        [ 0. , 1. , 0. , 0. ],
        [ 0. , 0. , 1. , 0. ],
        [ 1. , 0.5, 0.5, 1. ]])

>>> lu.U.A
array([[2., 0., 1., 4.],
        [0., 2., 1., 1.],
        [0., 0., 1., 1.],
        [0., 0., 0., -5.]])
```

The permutation matrices can be constructed:

```python
>>> Pr = csc_matrix((4, 4))
>>> Pr[lu.perm_r, np.arange(4)] = 1
>>> Pc = csc_matrix((4, 4))
>>> Pc[np.arange(4), lu.perm_c] = 1

We can reassemble the original matrix:

```python
>>> (Pr.T * (lu.L * lu.U) * Pc.T).A
array([[ 1., 2., 0., 4.],
        [ 1., 0., 0., 1.],
        [ 1., 0., 2., 1.],
        [ 2., 2., 1., 0.]])
```

**Attributes**

- `shape` : Shape of the original matrix as a tuple of ints.
- `nnz` : Number of nonzero elements in the matrix.
- `perm_c` : Permutation Pc represented as an array of indices.
- `perm_r` : Permutation Pr represented as an array of indices.
- `L` : Lower triangular factor with unit diagonal as a `scipy.sparse.csc_matrix`.
- `U` : Upper triangular factor as a `scipy.sparse.csc_matrix`.

**SuperLU.shape**

Shape of the original matrix as a tuple of ints.
SuperLU.nnz
Number of nonzero elements in the matrix.

SuperLU.perm_c
Permutation Pc represented as an array of indices.

The column permutation matrix can be reconstructed via:

```python
>>> Pc = np.zeros((n, n))
>>> Pc[np.arange(n), perm_c] = 1
```

SuperLU.perm_r
Permutation Pr represented as an array of indices.

The row permutation matrix can be reconstructed via:

```python
>>> Pr = np.zeros((n, n))
>>> Pr[perm_r, np.arange(n)] = 1
```

SuperLU.L
Lower triangular factor with unit diagonal as a \textit{scipy.sparse.csc_matrix}.

New in version 0.14.0.

SuperLU.U
Upper triangular factor as a \textit{scipy.sparse.csc_matrix}.

New in version 0.14.0.

\textit{Methods}

\texttt{solve(rhs[, trans])}
Solves linear system of equations with one or several right-hand sides.

\texttt{SuperLU.solve\ (rhs[,\ trans])}
Solves linear system of equations with one or several right-hand sides.

\textbf{Parameters}

rhs : ndarray, shape (n,) or (n, k)
Right hand side(s) of equation

Type of system to solve:

```
'N': A * x == rhs (default)
'T': A^T * x == rhs
'H': A^H * x == rhs
```

\textbf{Returns}

x : ndarray, shape rhs.shape
Solution vector(s)

5.22.6 Exceptions

\texttt{ArpackNoConvergence(msg, eigenvalues, ...)}
ARPACK iteration did not converge

\texttt{ArpackError(info[, infodict])}
ARPACK error

\textbf{exception} scipy.sparse.linalg.ArpcakNoConvergence \texttt{(msg, eigenvalues, eigenvectors)}
ARPACK iteration did not converge

5.22. Sparse linear algebra \texttt{(scipy.sparse.linalg)}

### scipy.sparse.csgraph.connected_components *(csgraph, directed=True, connection='weak', return_labels=True)*

Analyze the connected components of a sparse graph

New in version 0.11.0.

**Parameters**

- `csgraph` : array_like or sparse matrix
  - The N x N matrix representing the compressed sparse graph. The input csgraph will be converted to csr format for the calculation.
- `directed` : bool, optional
  - If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].
- `connection` : str, optional
  - ['weak'|'strong']. For directed graphs, the type of connection to use. Nodes i and j are strongly connected if a path exists both from i to j and from j to
i. Nodes i and j are weakly connected if only one of these paths exists. If directed == False, this keyword is not referenced.

**return_labels**: bool, optional

- If True (default), then return the labels for each of the connected components.

**Returns**

- n_components: int
  - The number of connected components.
- labels: ndarray
  - The length-N array of labels of the connected components.

**References**

[R314] scipy.sparse.csgraph.laplacian(csgraph, normed=False, return_diag=False, use_out_degree=False)

Return the Laplacian matrix of a directed graph.

**Parameters**

- csgraph : array_like or sparse matrix, 2 dimensions
  - compressed-sparse graph, with shape (N, N).
- normed : bool, optional
  - If True, then compute normalized Laplacian.
- return_diag : bool, optional
  - If True, then also return an array related to vertex degrees.
- use_out_degree : bool, optional
  - If True, then use out-degree instead of in-degree. This distinction matters only if the graph is asymmetric. Default: False.

**Returns**

- lap : ndarray or sparse matrix
  - The N x N laplacian matrix of csgraph. It will be a numpy array (dense) if the input was dense, or a sparse matrix otherwise.
- diag : ndarray, optional
  - The length-N diagonal of the Laplacian matrix. For the normalized Laplacian, this is the array of square roots of vertex degrees or 1 if the degree is zero.

**Notes**

The Laplacian matrix of a graph is sometimes referred to as the “Kirchoff matrix” or the “admittance matrix”, and is useful in many parts of spectral graph theory. In particular, the eigen-decomposition of the laplacian matrix can give insight into many properties of the graph.

**Examples**

```python
>>> from scipy.sparse import csgraph
>>> G = np.arange(5) * np.arange(5)[:, np.newaxis]
>>> G
array([[ 0,  0,  0,  0,  0],
       [ 0,  1,  2,  3,  4],
       [ 0,  2,  4,  6,  8],
       [ 0,  3,  6,  9, 12],
       [ 0,  4,  8, 12, 16]])
>>> csgraph.laplacian(G, normed=False)
array([[ 0,  0,  0,  0,  0],
       [ 0,  9, -2, -3, -4],
       [ 0, -2, 16, -6, -8],
       [ 0, -3, -6, 21, -12],
       [ 0, -4, -8, -12, 24]])
```
scipy.sparse.csgraph.shortest_path(csgraph, method='auto', directed=True, return_predecessors=False, unweighted=False, overwrite=False, indices=None)

Perform a shortest-path graph search on a positive directed or undirected graph.

New in version 0.11.0.

**Parameters**

- **csgraph**: array, matrix, or sparse matrix, 2 dimensions
  The N x N array of distances representing the input graph.

- **method**: string ['auto'|'FW'|'D'], optional
  Algorithm to use for shortest paths. Options are:
  - ‘FW’ – Floyd-Warshall algorithm. Computation cost is approximately \(O[N^3]\). The input csgraph will be converted to a dense representation.
  - ‘D’ – Dijkstra’s algorithm with Fibonacci heaps. Computation cost is approximately \(O[N(N*k + N*log(N))]\), where \(k\) is the average number of connected edges per node. The input csgraph will be converted to a csr representation.
  - ‘BF’ – Bellman-Ford algorithm. This algorithm can be used when weights are negative. If a negative cycle is encountered, an error will be raised. Computational cost is approximately \(O[N(N^2 k)]\), where \(k\) is the average number of connected edges per node. The input csgraph will be converted to a csr representation.
  - ‘J’ – Johnson’s algorithm. Like the Bellman-Ford algorithm, Johnson’s algorithm is designed for use when the weights are negative. It combines the Bellman-Ford algorithm with Dijkstra’s algorithm for faster computation.

- **directed**: bool, optional
  If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i]

- **return_predecessors**: bool, optional
  If True, return the size (N, N) predecessor matrix

- **unweighted**: bool, optional
  If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.

- **overwrite**: bool, optional
  If True, overwrite csgraph with the result. This applies only if method == ‘FW’ and csgraph is a dense, c-ordered array with dtype=\text{float64}.

- **indices**: array_like or int, optional
  If specified, only compute the paths for the points at the given indices. Incompatible with method == ‘FW’.

**Returns**

- **dist_matrix**: ndarray
The N x N matrix of distances between graph nodes. dist_matrix[i,j] gives
the shortest distance from point i to point j along the graph.

predecessors : ndarray
 retour only if return_predecessors == True. The N x N matrix of prede-
cessors, which can be used to reconstruct the shortest paths. Row i of the
predecessor matrix contains information on the shortest paths from point
i: each entry predecessors[i, j] gives the index of the previous node in the
path from point i to point j. If no path exists between point i and j, then
predecessors[i, j] = -9999

Raises
NegativeCycleError:
if there are negative cycles in the graph

Notes
As currently implemented, Dijkstra's algorithm and Johnson's algorithm do not work for graphs with direction-
dependent distances when directed == False. i.e., if csgraph[i,j] and csgraph[j,i] are non-equal edges,
method='D' may yield an incorrect result.

scipy.sparse.csgraph.dijkstra(csgraph, directed=True, indices=None, return_predecessors=False, unweighted=False, limit=np.inf)
Dijkstra algorithm using Fibonacci Heaps
New in version 0.11.0.

Parameters
csgraph : array, matrix, or sparse matrix, 2 dimensions
The N x N array of non-negative distances representing the input graph.
directed : bool, optional
If True (default), then find the shortest path on a directed graph: only move
from point i to point j along paths csgraph[i, j]. If False, then find the
shortest path on an undirected graph: the algorithm can progress from point
i to j along csgraph[i, j] or csgraph[j, i]
indices : array_like or int, optional
if specified, only compute the paths for the points at the given indices.
return_predecessors : bool, optional
If True, return the size (N, N) predecessor matrix
unweighted : bool, optional
If True, then find unweighted distances. That is, rather than finding the path
between each point such that the sum of weights is minimized, find the path
such that the number of edges is minimized.
limit : float, optional
The maximum distance to calculate, must be >= 0. Using a smaller limit
will decrease computation time by aborting calculations between pairs that
are separated by a distance > limit. For such pairs, the distance will be equal
to np.inf (i.e., not connected).

Returns
dist_matrix : ndarray
The matrix of distances between graph nodes. dist_matrix[i,j] gives the
shortest distance from point i to point j along the graph.

predecessors : ndarray
Retumed only if return_predecessors == True. The matrix of predecessors,
which can be used to reconstruct the shortest paths. Row i of the prede-
cessor matrix contains information on the shortest paths from point i: each
entry predecessors[i, j] gives the index of the previous node in the path from
point i to point j. If no path exists between point i and j, then predecessors[i,
j] = -9999
Notes

As currently implemented, Dijkstra’s algorithm does not work for graphs with direction-dependent distances when directed == False. i.e., if csgraph[i,j] and csgraph[j,i] are not equal and both are nonzero, setting directed=False will not yield the correct result.

Also, this routine does not work for graphs with negative distances. Negative distances can lead to infinite cycles that must be handled by specialized algorithms such as Bellman-Ford’s algorithm or Johnson’s algorithm.

```
scipy.sparse.csgraph.floyd_warshall(csgraph, directed=True, return_predecessors=False, unweighted=False, overwrite=False)
```

Compute the shortest path lengths using the Floyd-Warshall algorithm

New in version 0.11.0.

**Parameters**

- `csgraph`: array, matrix, or sparse matrix, 2 dimensions
  The N x N array of distances representing the input graph.
- `directed`: bool, optional
  If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i]
- `return_predecessors`: bool, optional
  If True, return the size (N, N) predecessor matrix
- `unweighted`: bool, optional
  If True, then find unweighted distances. That is, rather than finding the path between each point such that the sum of weights is minimized, find the path such that the number of edges is minimized.
- `overwrite`: bool, optional
  If True, overwrite csgraph with the result. This applies only if csgraph is a dense, c-ordered array with dtype=float64.

**Returns**

- `dist_matrix`: ndarray
  The N x N matrix of distances between graph nodes. dist_matrix[i,j] gives the shortest distance from point i to point j along the graph.
- `predecessors`: ndarray
  Returned only if return_predecessors == True. The N x N matrix of predecessors, which can be used to reconstruct the shortest paths. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry predecessors[i, j] gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then predecessors[i, j] = -9999

**Raises**

- `NegativeCycleError`: if there are negative cycles in the graph

```
scipy.sparse.csgraph.bellman_ford(csgraph, directed=True, indices=None, return_predecessors=False, unweighted=False)
```

Compute the shortest path lengths using the Bellman-Ford algorithm.

The Bellman-ford algorithm can robustly deal with graphs with negative weights. If a negative cycle is detected, an error is raised. For graphs without negative edge weights, Dijkstra’s algorithm may be faster.

New in version 0.11.0.

**Parameters**

- `csgraph`: array, matrix, or sparse matrix, 2 dimensions
  The N x N array of distances representing the input graph.
- `directed`: bool, optional
  If True (default), then find the shortest path on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i]
indices : array_like or int, optional
    if specified, only compute the paths for the points at the given indices.

return_predecessors : bool, optional
    If True, return the size (N, N) predecessor matrix

unweighted : bool, optional
    If True, then find unweighted distances. That is, rather than finding the path
    between each point such that the sum of weights is minimized, find the path
    such that the number of edges is minimized.

Returns

dist_matrix : ndarray
    The N x N matrix of distances between graph nodes. dist_matrix[i,j] gives
    the shortest distance from point i to point j along the graph.

predecessors : ndarray
    Returned only if return_predecessors == True. The N x N matrix of prede-
    cessors, which can be used to reconstruct the shortest paths. Row i of the
    predecessor matrix contains information on the shortest paths from point
    i: each entry predecessors[i, j] gives the index of the previous node in the
    path from point i to point j. If no path exists between point i and j, then
    predecessors[i, j] = -9999

Raises

NegativeCycleError:
    if there are negative cycles in the graph

Notes

This routine is specially designed for graphs with negative edge weights. If all edge weights are positive, then
Dijkstra’s algorithm is a better choice.

scipy.sparse.csgraph.johnson(csgraph, directed=True, indices=None, return_predecessors=False, unweighted=False)

Compute the shortest path lengths using Johnson’s algorithm.

Johnson’s algorithm combines the Bellman-Ford algorithm and Dijkstra’s algorithm to quickly find shortest
paths in a way that is robust to the presence of negative cycles. If a negative cycle is detected, an error is raised.
For graphs without negative edge weights, dijkstra() may be faster.

New in version 0.11.0.

Parameters
csgraph : array, matrix, or sparse matrix, 2 dimensions
    The N x N array of distances representing the input graph.
directed : bool, optional
    If True (default), then find the shortest path on a directed graph: only move
    from point i to point j along paths csgraph[i, j]. If False, then find the
    shortest path on an undirected graph: the algorithm can progress from point
    i to j along csgraph[i, j] or csgraph[j, i]
indices : array_like or int, optional
    if specified, only compute the paths for the points at the given indices.
return_predecessors : bool, optional
    If True, return the size (N, N) predecessor matrix
unweighted : bool, optional
    If True, then find unweighted distances. That is, rather than finding the path
    between each point such that the sum of weights is minimized, find the path
    such that the number of edges is minimized.

Returns
dist_matrix : ndarray
    The N x N matrix of distances between graph nodes. dist_matrix[i,j] gives
    the shortest distance from point i to point j along the graph.
predecessors : ndarray
    Returned only if return_predecessors == True. The N x N matrix of prede-
    cessors, which can be used to reconstruct the shortest paths. Row i of the
    predecessor matrix contains information on the shortest paths from point

5.23. Compressed Sparse Graph Routines (scipy.sparse.csgraph) 1479
SciPy Reference Guide, Release 1.0.0

i: each entry predecessors[i, j] gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then predecessors[i, j] = -9999

Raises

NegativeCycleError:

if there are negative cycles in the graph

Notes

This routine is specially designed for graphs with negative edge weights. If all edge weights are positive, then Dijkstra’s algorithm is a better choice.

scipy.sparse.csgraph.breadth_first_order(csgraph, i_start, directed=True, return_predecessors=True)

Return a breadth-first ordering starting with specified node.

New in version 0.11.0.

Parameters

csgraph : array_like or sparse matrix
The N x N compressed sparse graph. The input csgraph will be converted to csr format for the calculation.
i_start : int
The index of starting node.
directed : bool, optional
If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].

Returns

node_array : ndarray, one dimension
The breadth-first list of nodes, starting with specified node. The length of node_array is the number of nodes reachable from the specified node.

predecessors : ndarray, one dimension
Returned only if return_predecessors is True. The length-N list of predecessors of each node in a breadth-first tree. If node i is in the tree, then its parent is given by predecessors[i]. If node i is not in the tree (and for the parent node) then predecessors[i] = -9999.

scipy.sparse.csgraph.depth_first_order(csgraph, i_start, directed=True, return_predecessors=True)

Return a depth-first ordering starting with specified node.

New in version 0.11.0.

Parameters

csgraph : array_like or sparse matrix
The N x N compressed sparse graph. The input csgraph will be converted to csr format for the calculation.
i_start : int
The index of starting node.
directed : bool, optional
If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].

return_predecessors : bool, optional
If True (default), then return the predecessor array (see below).

Returns

node_array : ndarray, one dimension
The depth-first list of nodes, starting with specified node. The length of
node_array is the number of nodes reachable from the specified node.

predecessors : ndarray, one dimension
Returned only if return_predecessors is True. The length-N list of prede-
cessors of each node in a depth-first tree. If node i is in the tree, then its
parent is given by predecessors[i]. If node i is not in the tree (and for the
parent node) then predecessors[i] = -9999.

scipy.sparse.csgraph.breadth_first_tree (csgraph, i_start, directed=True)

Return the tree generated by a breadth-first search

Note that a breadth-first tree from a specified node is unique.

New in version 0.11.0.

Parameters

csgraph : array_like or sparse matrix
The N x N matrix representing the compressed sparse graph. The input
csgraph will be converted to csr format for the calculation.

i_start : int
The index of starting node.

directed : bool, optional
If True (default), then operate on a directed graph: only move from point
i to point j along paths csgraph[i, j]. If False, then find the shortest path
on an undirected graph: the algorithm can progress from point i to j along
csgraph[i, j] or csgraph[j, i].

Returns
cstree : csr matrix
The N x N directed compressed-sparse representation of the breadth-first
tree drawn from csgraph, starting at the specified node.

Examples

The following example shows the computation of a depth-first tree over a simple four-component graph, starting
at node 0:

In compressed sparse representation, the solution looks like this:

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import breadth_first_tree
>>> X = csr_matrix([[0, 8, 0, 3],
                  [0, 0, 2, 5],
                  [0, 0, 0, 6],
                  [0, 0, 0, 0]])
>>> Tcsr = breadth_first_tree(X, 0, directed=False)
>>> Tcsr.toarray().astype(int)
array([[0, 8, 0, 3],
       [0, 0, 2, 5],
       [0, 0, 0, 6],
       [0, 0, 0, 0]])
```
SciPy Reference Guide, Release 1.0.0

scipy.sparse.csgraph.depth_first_tree(csgraph, i_start, directed=True)

Return a tree generated by a depth-first search.

Note that a tree generated by a depth-first search is not unique: it depends on the order that the children of each node are searched.

New in version 0.11.0.

Parameters

- csgraph : array_like or sparse matrix
  The N x N matrix representing the compressed sparse graph. The input csgraph will be converted to csr format for the calculation.

- i_start : int
  The index of starting node.

- directed : bool, optional
  If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then find the shortest path on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].

Returns

- cstree : csr matrix
  The N x N directed compressed-sparse representation of the depth-first tree drawn from csgraph, starting at the specified node.

Examples

The following example shows the computation of a depth-first tree over a simple four-component graph, starting at node 0:

In compressed sparse representation, the solution looks like this:

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import depth_first_tree

>>> X = csr_matrix(
    [[0, 8, 0, 3],
     [0, 0, 2, 5],
     [0, 0, 0, 6],
     [0, 0, 0, 0]])

>>> Tcsr = depth_first_tree(X, 0, directed=False)

>>> Tcsr.toarray().astype(int)
array([[0, 8, 0, 0],
       [0, 0, 2, 0],
       [0, 0, 0, 0],
       [0, 0, 0, 0]])
```
Note that the resulting graph is a Directed Acyclic Graph which spans the graph. Unlike a breadth-first tree, a depth-first tree of a given graph is not unique if the graph contains cycles. If the above solution had begun with the edge connecting nodes 0 and 3, the result would have been different.

scipy.sparse.csgraph.minimum_spanning_tree(csgraph, overwrite=False)

Return a minimum spanning tree of an undirected graph

A minimum spanning tree is a graph consisting of the subset of edges which together connect all connected nodes, while minimizing the total sum of weights on the edges. This is computed using the Kruskal algorithm.

New in version 0.11.0.

Parameters

csgraph : array_like or sparse matrix, 2 dimensions
The N x N matrix representing an undirected graph over N nodes (see notes below).

overwrite : bool, optional
if true, then parts of the input graph will be overwritten for efficiency.

Returns

span_tree : csr matrix
The N x N compressed-sparse representation of the undirected minimum spanning tree over the input (see notes below).

Notes

This routine uses undirected graphs as input and output. That is, if graph[i, j] and graph[j, i] are both zero, then nodes i and j do not have an edge connecting them. If either is nonzero, then the two are connected by the minimum nonzero value of the two.

Examples

The following example shows the computation of a minimum spanning tree over a simple four-component graph:

\[
\begin{array}{c}
\text{input graph} & \text{minimum spanning tree} \\
\begin{array}{c}
(0) \\
/ \ \\
3 & 8 & 3 \\
/ \\
(3)---5---(1) \\
/ \\
6 & 2 \\
/ \\
(2)
\end{array} & \begin{array}{c}
(0) \\
/ \\
(3)---5---(1) \\
/ \\
2 \\
/ \\
(2)
\end{array}
\end{array}
\]

It is easy to see from inspection that the minimum spanning tree involves removing the edges with weights 8 and 6. In compressed sparse representation, the solution looks like this:

```python
>>> from scipy.sparse import csr_matrix
>>> from scipy.sparse.csgraph import minimum_spanning_tree

>>> X = csr_matrix([[0, 8, 0, 3],
...                  [0, 0, 2, 5],
...                  [0, 0, 0, 6],
...                  [0, 0, 0, 0]])

>>> Tcsr = minimum_spanning_tree(X)

array([[0, 0, 3],
        [0, 0, 0],
        [0, 0, 0],
        [0, 0, 0]])
```
scipy.sparse.csgraph.reverse_cuthill_mckee(graph, symmetric_mode=False)

Returns the permutation array that orders a sparse CSR or CSC matrix in Reverse-Cuthill McKee ordering.

It is assumed by default, symmetric_mode=False, that the input matrix is not symmetric and works on the matrix A+A.T. If you are guaranteed that the matrix is symmetric in structure (values of matrix elements do not matter) then set symmetric_mode=True.

**Parameters**
- **graph**: sparse matrix
  - Input sparse in CSC or CSR sparse matrix format.
- **symmetric_mode**: bool, optional
  - Is input matrix guaranteed to be symmetric.

**Returns**
- **perm**: ndarray
  - Array of permuted row and column indices.

**Notes**
New in version 0.15.0.

**References**

scipy.sparse.csgraph.maximum_bipartite_matching(graph, perm_type='row')

Returns an array of row or column permutations that makes the diagonal of a nonsingular square CSC sparse matrix zero free.

Such a permutation is always possible provided that the matrix is nonsingular. This function looks at the structure of the matrix only. The input matrix will be converted to CSC matrix format if necessary.

**Parameters**
- **graph**: sparse matrix
  - Input sparse in CSC format
- **perm_type**: str, {'row', 'column'}
  - Type of permutation to generate.

**Returns**
- **perm**: ndarray
  - Array of row or column permutations.

**Notes**
This function relies on a maximum cardinality bipartite matching algorithm based on a breadth-first search (BFS) of the underlying graph.

New in version 0.15.0.

**References**

scipy.sparse.csgraph.structural_rank(graph)

Compute the structural rank of a graph (matrix) with a given sparsity pattern.

The structural rank of a matrix is the number of entries in the maximum transversal of the corresponding bipartite graph, and is an upper bound on the numerical rank of the matrix. A graph has full structural rank if it is possible to permute the elements to make the diagonal zero-free.

**Parameters**
- **graph**: sparse matrix
  - Input sparse matrix.
Returns

rank : int

The structural rank of the sparse graph.
New in version 0.19.0.

References

[R315], [R316]

exception scipy.sparse.csgraph.NegativeCycleError

construct_dist_matrix(graph, predecessors[, ...]) Construct distance matrix from a predecessor matrix
New in version 0.11.0.

Parameters

graph : array_like or sparse
The N x N matrix representation of a directed or undirected graph. If dense, then non-edges are indicated by zeros or infinities.

predecessors : array_like
The N x N matrix of predecessors of each node (see Notes below).

directed : bool, optional
If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then operate on an undirected graph: the algorithm can progress from point i to j along csgraph[i, j] or csgraph[j, i].

null_value : bool, optional
value to use for distances between unconnected nodes. Default is np.inf

Returns

dist_matrix : ndarray
The N x N matrix of distances between nodes along the path specified by the predecessor matrix. If no path exists, the distance is zero.

Notes

The predecessor matrix is of the form returned by graph_shortest_path. Row i of the predecessor matrix contains information on the shortest paths from point i: each entry predecessors[i, j] gives the index of the previous node in the path from point i to point j. If no path exists between point i and j, then predecessors[i, j] = -9999

scipy.sparse.csgraph.cscgraph_from_dense(graph, null_value=0, nan_null=True, infinity_null=True)

Construct a CSR-format sparse graph from a dense matrix.
New in version 0.11.0.

Parameters

graph : array_like
Input graph. Shape should be (n_nodes, n_nodes).

null_value : float or None (optional)
    Value that denotes non-edges in the graph. Default is zero.

infinity_null : bool
    If True (default), then infinite entries (both positive and negative) are treated
    as null edges.

nan_null : bool
    If True (default), then NaN entries are treated as non-edges

Returns

csgraph : csr_matrix
    Compressed sparse representation of graph,

scipy.sparse.csgraph.csgraph_from_masked(graph)
Construct a CSR-format graph from a masked array.

New in version 0.11.0.

Parameters

graph : MaskedArray

Returns

csgraph : csr_matrix
    Compressed sparse representation of graph,

scipy.sparse.csgraph.csgraph_masked_from_dense(graph, null_value=0, nan_null=True, infinity_null=True, copy=True)
Construct a masked array graph representation from a dense matrix.

New in version 0.11.0.

Parameters

graph : array_like
    Input graph. Shape should be (n_nodes, n_nodes).

null_value : float or None (optional)
    Value that denotes non-edges in the graph. Default is zero.

infinity_null : bool
    If True (default), then infinite entries (both positive and negative) are treated
    as null edges.

nan_null : bool
    If True (default), then NaN entries are treated as non-edges

Returns

csgraph : MaskedArray
    MaskedArray representation of graph

scipy.sparse.csgraph.csgraph_to_dense(csgraph, null_value=0)
Convert a sparse graph representation to a dense representation

New in version 0.11.0.

Parameters

csgraph : csr_matrix, csc_matrix, or lil_matrix
    Sparse representation of a graph.

null_value : float, optional
    The value used to indicate null edges in the dense representation. Default is
    0.

Returns

graph : ndarray
    The dense representation of the sparse graph.

Notes

For normal sparse graph representations, calling csgraph_to_dense with null_value=0 produces an equivalent
result to using dense format conversions in the main sparse package. When the sparse representations have
repeated values, however, the results will differ. The tools in scipy.sparse will add repeating values to obtain a
final value. This function will select the minimum among repeating values to obtain a final value. For example,
here we’ll create a two-node directed sparse graph with multiple edges from node 0 to node 1, of weights 2 and
3. This illustrates the difference in behavior:
The reason for this difference is to allow a compressed sparse graph to represent multiple edges between any two nodes. As most sparse graph algorithms are concerned with the single lowest-cost edge between any two nodes, the default scipy.sparse behavior of summing multiple weights does not make sense in this context.

The other reason for using this routine is to allow for graphs with zero-weight edges. Let’s look at the example of a two-node directed graph, connected by an edge of weight zero:

```python
>>> from scipy.sparse import csr_matrix, csgraph
>>>
data = np.array([0.0])
>>> indices = np.array([1])
>>> indptr = np.array([0, 1, 1])
>>> M = csr_matrix((data, indices, indptr), shape=(2, 2))
>>> M.toarray()
array([[0., 0.],
       [inf, inf]])
```

In the first case, the zero-weight edge gets lost in the dense representation. In the second case, we can choose a different null value and see the true form of the graph.

scipy.sparse.csgraph.csgraph_to_masked(csgraph)
Convert a sparse graph representation to a masked array representation

New in version 0.11.0.

**Parameters**
- **csgraph**: csr_matrix, csc_matrix, or lil_matrix

**Returns**
- **graph**: MaskedArray
  Sparse representation of a graph.

The masked dense representation of the sparse graph.

scipy.sparse.csgraph.reconstruct_path(csgraph, predecessors, directed=True)
Construct a tree from a graph and a predecessor list.

New in version 0.11.0.

**Parameters**
- **csgraph**: array_like or sparse matrix
  The N x N matrix representing the directed or undirected graph from which the predecessors are drawn.
- **predecessors**: array_like, one dimension
  The length-N array of indices of predecessors for the tree. The index of the parent of node i is given by predecessors[i].
- **directed**: bool, optional
  If True (default), then operate on a directed graph: only move from point i to point j along paths csgraph[i, j]. If False, then operate on an undirected
Returns
cstree : csr matrix

The N x N directed compressed-sparse representation of the tree drawn from csgraph which is encoded by the predecessor list.

5.23.2 Graph Representations

This module uses graphs which are stored in a matrix format. A graph with N nodes can be represented by an (N x N) adjacency matrix G. If there is a connection from node i to node j, then G[i, j] = w, where w is the weight of the connection. For nodes i and j which are not connected, the value depends on the representation:

- for dense array representations, non-edges are represented by G[i, j] = 0, infinity, or NaN.
- for dense masked representations (of type np.ma.MaskedArray), non-edges are represented by masked values. This can be useful when graphs with zero-weight edges are desired.
- for sparse array representations, non-edges are represented by non-entries in the matrix. This sort of sparse representation also allows for edges with zero weights.

As a concrete example, imagine that you would like to represent the following undirected graph:

This graph has three nodes, where node 0 and 1 are connected by an edge of weight 2, and nodes 0 and 2 are connected by an edge of weight 1. We can construct the dense, masked, and sparse representations as follows, keeping in mind that an undirected graph is represented by a symmetric matrix:

```
G = np.array([[0, 2, 1],
              [2, 0, 0],
              [1, 0, 0]])
```

```
G_masked = np.ma.masked_values(G, 0)
```

```
from scipy.sparse import csr_matrix
G_sparse = csr_matrix(G_dense)
```

This becomes more difficult when zero edges are significant. For example, consider the situation when we slightly modify the above graph:

This is identical to the previous graph, except nodes 0 and 2 are connected by an edge of zero weight. In this case, the dense representation above leads to ambiguities: how can non-edges be represented if zero is a meaningful value? In this case, either a masked or sparse representation must be used to eliminate the ambiguity:

```
G2_data = np.array([[np.inf, 2, 0],
                    [2, np.inf, np.inf],
                    [1, 0, 0]])
```

```
Here we have used a utility routine from the csgraph submodule in order to convert the dense representation to a sparse representation which can be understood by the algorithms in submodule. By viewing the data array, we can see that the zero values are explicitly encoded in the graph.

**Directed vs. Undirected**

Matrices may represent either directed or undirected graphs. This is specified throughout the csgraph module by a boolean keyword. Graphs are assumed to be directed by default. In a directed graph, traversal from node i to node j can be accomplished over the edge G[i, j], but not the edge G[j, i]. In a non-directed graph, traversal from node i to node j can be accomplished over either G[i, j] or G[j, i]. If both edges are not null, and the two have unequal weights, then the smaller of the two is used. Note that a symmetric matrix will represent an undirected graph, regardless of whether the ‘directed’ keyword is set to True or False. In this case, using directed=True generally leads to more efficient computation.

The routines in this module accept as input either scipy.sparse representations (csr, csc, or lil format), masked representations, or dense representations with non-edges indicated by zeros, infinities, and NaN entries.

## 5.24 Spatial algorithms and data structures (scipy.spatial)

### 5.24.1 Nearest-neighbor Queries

<table>
<thead>
<tr>
<th>KDTree(data[, leafsize])</th>
<th>KDTree for quick nearest-neighbor lookup</th>
</tr>
</thead>
<tbody>
<tr>
<td>cKDTree</td>
<td>KD-tree for quick nearest-neighbor lookup</td>
</tr>
<tr>
<td>distance</td>
<td></td>
</tr>
<tr>
<td>Rectangle(maxes, mins)</td>
<td>Hyperrectangle class.</td>
</tr>
</tbody>
</table>

**class** scipy.spatial.KDTree(data, leafsize=10)

kd-tree for quick nearest-neighbor lookup

This class provides an index into a set of k-dimensional points which can be used to rapidly look up the nearest neighbors of any point.

**Parameters**

- **data** : (N,K) array_like
  
The data points to be indexed. This array is not copied, and so modifying this data will result in bogus results.

- **leafsize** : int, optional
  
The number of points at which the algorithm switches over to brute-force. Has to be positive.

**Raises**

- **RuntimeError**
  
The maximum recursion limit can be exceeded for large data sets. If this happens, either increase the value for the leafsize parameter or increase the recursion limit by:
>>> import sys
>>> sys.setrecursionlimit(10000)

See also:

cKDTree  Implementation of KDTree in Cython

Notes
The algorithm used is described in Maneewongvatana and Mount 1999. The general idea is that the kd-tree is a binary tree, each of whose nodes represents an axis-aligned hyperrectangle. Each node specifies an axis and splits the set of points based on whether their coordinate along that axis is greater than or less than a particular value.

During construction, the axis and splitting point are chosen by the "sliding midpoint" rule, which ensures that the cells do not all become long and thin.

The tree can be queried for the r closest neighbors of any given point (optionally returning only those within some maximum distance of the point). It can also be queried, with a substantial gain in efficiency, for the r approximate closest neighbors.

For large dimensions (20 is already large) do not expect this to run significantly faster than brute force. High-dimensional nearest-neighbor queries are a substantial open problem in computer science.

The tree also supports all-neighbors queries, both with arrays of points and with other kd-trees. These do use a reasonably efficient algorithm, but the kd-tree is not necessarily the best data structure for this sort of calculation.

Methods

count_neighbors(other, r[, p])  Count how many nearby pairs can be formed.
innernode(split_dim, split, less, greater)
leafnode(idx)
node
query(x[, k, eps, p, distance_upper_bound])  Query the kd-tree for nearest neighbors
query_ball_point(x, r[, p, eps])  Find all points within distance r of point(s) x.
query_ball_tree(other, r[, p, eps])  Find all pairs of points whose distance is at most r
query_pairs(r[, p, eps])  Find all pairs of points within a distance.
sparse_distance_matrix(other, max_distance)  Compute a sparse distance matrix

KDTreecount_neighbors(other, r, p=2.0)
Count how many nearby pairs can be formed.
Count the number of pairs (x1,x2) can be formed, with x1 drawn from self and x2 drawn from other, and where distance(x1, x2, p) <= r. This is the “two-point correlation” described in Gray and Moore 2000, “N-body problems in statistical learning”, and the code here is based on their algorithm.

Parameters
other : KDTree instance
    The other tree to draw points from.
r : float or one-dimensional array of floats
    The radius to produce a count for. Multiple radii are searched with a single tree traversal.
p : float, 1<=p<=infinity, optional
    Which Minkowski p-norm to use

Returns
result : int or 1-D array of ints
    The number of pairs. Note that this is internally stored in a numpy int, and so may overflow if very large (2e9).
KDTree.query (x, k=1, eps=0, p=2, distance_upper_bound=inf)

Query the kd-tree for nearest neighbors

Parameters

- x : array_like, last dimension self.m
  An array of points to query.
- k : int, optional
  The number of nearest neighbors to return.
- eps : nonnegative float, optional
  Return approximate nearest neighbors; the kth returned value is guaran-
  teed to be no further than (1+eps) times the distance to the real kth
  nearest neighbor.
- p : float, 1<=p<=infinity, optional
  Which Minkowski p-norm to use. 1 is the sum-of-absolute-values
  "Manhattan" distance 2 is the usual Euclidean distance infinity is the
  maximum-coordinate-difference distance
- distance_upper_bound : nonnegative float, optional
  Return only neighbors within this distance. This is used to prune tree
  searches, so if you are doing a series of nearest-neighbor queries, it
  may help to supply the distance to the nearest neighbor of the most
  recent point.

Returns

- d : float or array of floats
  The distances to the nearest neighbors. If x has shape tuple+(self.m,),
  then d has shape tuple if k is one, or tuple+(k,) if k is larger than
  one. Missing neighbors (e.g. when k > n or distance_upper_bound
  is given) are indicated with infinite distances. If k is None, then d is
  an object array of shape tuple, containing lists of distances. In either
  case the hits are sorted by distance (nearest first).
- i : integer or array of integers
  The locations of the neighbors in self.data. i is the same shape as d.

Examples

```python
>>> from scipy import spatial
>>> x, y = np.mgrid[0:5, 2:8]
>>> tree = spatial.KDTree(list(zip(x.ravel(), y.ravel())))
>>> tree.data
array([[0, 2],
       [0, 3],
       [0, 4],
       [0, 5],
       [0, 6],
       [0, 7],
       [1, 2],
       [1, 3],
       [1, 4],
       [1, 5],
       [1, 6],
       [1, 7],
       [2, 2],
       [2, 3],
       [2, 4],
       [2, 5],
       [2, 6],
       [2, 7],
       [3, 2],
       [3, 3],
       [3, 4]], dtype=int32)
```
[3, 5],
[3, 6],
[3, 7],
[4, 2],
[4, 3],
[4, 4],
[4, 5],
[4, 6],
[4, 7])

```python
>>> pts = np.array([[0, 0], [2.1, 2.9]])
```

```python
>>> tree.query(pts)
(array([ 2. , 0.14142136]), array([ 0, 13]))
```

```python
>>> tree.query(pts[0])
(2.0, 0)
```

KDTree.query_ball_point (x, r, p=2.0, eps=0)
Find all points within distance r of point(s) x.

**Parameters**

- **x**: array_like, shape tuple + (self.m,)
  The point or points to search for neighbors of.
- **r**: positive float
  The radius of points to return.
- **p**: float, optional
  Which Minkowski p-norm to use. Should be in the range [1, inf].
- **eps**: nonnegative float, optional
  Approximate search. Branches of the tree are not explored if their nearest points are further than r / (1 + eps), and branches are added in bulk if their furthest points are nearer than r * (1 + eps).

**Returns**

- **results**: list or array of lists
  If x is a single point, returns a list of the indices of the neighbors of x. If x is an array of points, returns an object array of shape tuple containing lists of neighbors.

**Notes**

If you have many points whose neighbors you want to find, you may save substantial amounts of time by putting them in a KDTree and using query_ball_tree.

**Examples**

```python
>>> from scipy import spatial
>>> x, y = np.mgrid[0:5, 0:5]
>>> points = np.c_[x.ravel(), y.ravel()]
>>> tree = spatial.KDTree(points)
>>> tree.query_ball_point([[2, 0], [3, 3]], 1)
[5, 10, 11, 15]
```

Query multiple points and plot the results:

```python
>>> import matplotlib.pyplot as plt
>>> points = np.asarray(points)
>>> plt.plot(points[:,0], points[:,1], '.
```

```python
>>> for results in tree.query_ball_point([[2, 0], [3, 3]], 1):
...    nearby_points = points[results]
...    plt.plot(nearby_points[:,0], nearby_points[:,1], 'o')
>>> plt.margins(0.1, 0.1)
>>> plt.show()
```
KDTree.query_ball_tree(other, r, p=2.0, eps=0)

Find all pairs of points whose distance is at most r

**Parameters**

- **other**: KDTree instance
  - The tree containing points to search against.
- **r**: float
  - The maximum distance, has to be positive.
- **p**: float, optional
  - Which Minkowski norm to use. p has to meet the condition $1 \leq p \leq \infty$.
- **eps**: float, optional
  - Approximate search. Branches of the tree are not explored if their nearest points are further than $r/(1+\text{eps})$, and branches are added in bulk if their furthest points are nearer than $r \times (1+\text{eps})$. eps has to be non-negative.

**Returns**

- **results**: list of lists
  - For each element `self.data[i]` of this tree, `results[i]` is a list of the indices of its neighbors in `other.data`.

KDTree.query_pairs(r, p=2.0, eps=0)

Find all pairs of points within a distance.

**Parameters**

- **r**: positive float
  - The maximum distance.
- **p**: float, optional
  - Which Minkowski norm to use. p has to meet the condition $1 \leq p \leq \infty$.
- **eps**: float, optional
  - Approximate search. Branches of the tree are not explored if their nearest points are further than $r/(1+\text{eps})$, and branches are added in bulk if their furthest points are nearer than $r \times (1+\text{eps})$. eps has to be non-negative.

**Returns**

- **results**: set
  - Set of pairs $(i, j)$, with $i < j$, for which the corresponding positions are close.

KDTree.sparse_distance_matrix(other, max_distance, p=2.0)

Compute a sparse distance matrix

Computes a distance matrix between two KDTrees, leaving as zero any distance greater than max_distance.

**Parameters**
- **other**: KDTree
- **max_distance**: positive float
- **p**: float, optional

**Returns**
- **result**: dok_matrix

Sparse matrix representing the results in “dictionary of keys” format.

**class** scipy.spatial.cKDTree

kd-tree for quick nearest-neighbor lookup

This class provides an index into a set of k-dimensional points which can be used to rapidly look up the nearest neighbors of any point.

The algorithm used is described in Maneewongvatana and Mount 1999. The general idea is that the kd-tree is a binary trie, each of whose nodes represents an axis-aligned hyperrectangle. Each node specifies an axis and splits the set of points based on whether their coordinate along that axis is greater than or less than a particular value.

During construction, the axis and splitting point are chosen by the “sliding midpoint” rule, which ensures that the cells do not all become long and thin.

The tree can be queried for the r closest neighbors of any given point (optionally returning only those within some maximum distance of the point). It can also be queried, with a substantial gain in efficiency, for the r approximate closest neighbors.

For large dimensions (20 is already large) do not expect this to run significantly faster than brute force. High-dimensional nearest-neighbor queries are a substantial open problem in computer science.

**Parameters**
- **data**: array_like, shape (n,m)
  The n data points of dimension m to be indexed. This array is not copied unless this is necessary to produce a contiguous array of doubles, and so modifying this data will result in bogus results. The data are also copied if the kd-tree is built with copy_data=True.

- **leafsize**: positive int, optional
  The number of points at which the algorithm switches over to brute-force. Default: 16.

- **compact_nodes**: bool, optional
  If True, the kd-tree is built to shrink the hyperrectangles to the actual data range. This usually gives a more compact tree that is robust against degenerated input data and gives faster queries at the expense of longer build time. Default: True.

- **copy_data**: bool, optional
  If True the data is always copied to protect the kd-tree against data corruption. Default: False.

- **balanced_tree**: bool, optional
  If True, the median is used to split the hyperrectangles instead of the midpoint. This usually gives a more compact tree and faster queries at the expense of longer build time. Default: True.

- **boxsize**: array_like or scalar, optional
  Apply a m-d toroidal topology to the KDTree. The topology is generated by $x_i + n_i L_i$ where $n_i$ are integers and $L_i$ is the boxsize along i-th dimension. The input data shall be wrapped into $[0, L_i)$. A ValueError is raised if any of the data is outside of this bound.

**Methods**

cKDTree.**count_neighbors** *(self, other, r[, p, ...])*  
Count how many nearby pairs can be formed. (pair-counting)

Count the number of pairs (x1,x2) can be formed, with x1 drawn from self and x2 drawn from other, and where distance(x1, x2, p) <= r.

Data points on self and other are optionally weighted by the weights argument. (See below)

The algorithm we implement here is based on [R401]. See notes for further discussion.

**Parameters**

- `other` : cKDTree instance  
The other tree to draw points from, can be the same tree as self.
- `r` : float or one-dimensional array of floats  
The radius to produce a count for. Multiple radii are searched with a single tree traversal. If the count is non-cumulative(cumulative=False), r defines the edges of the bins, and must be non-decreasing.
- `p` : float, optional  
1<=p<=infinity. Which Minkowski p-norm to use. Default 2.0.
- `weights` : tuple, array_like, or None, optional  
If None, the pair-counting is unweighted. If given as a tuple, weights[0] is the weights of points in self, and weights[1] is the weights of points in other; either can be None to indicate the points are unweighted. If given as an array_like, weights is the weights of points in self and other. For this to make sense, self and other must be the same tree. If self and other are two different trees, a ValueError is raised. Default: None
cumulative : bool, optional

Whether the returned counts are cumulative. When cumulative is set to False the algorithm is optimized to work with a large number of bins (>10) specified by \( r \). When cumulative is set to True, the algorithm is optimized to work with a small number of \( r \). Default: True

Returns result : scalar or 1-D array

The number of pairs. For unweighted counts, the result is integer. For weighted counts, the result is float. If cumulative is False, result[i] contains the counts with \((-\infty \text{ if } i == 0 \text{ else } r[i-1]) < R <= r[i]\)

Notes

Pair-counting is the basic operation used to calculate the two point correlation functions from a data set composed of position of objects.

Two point correlation function measures the clustering of objects and is widely used in cosmology to quantify the large scale structure in our Universe, but it may be useful for data analysis in other fields where self-similar assembly of objects also occur.

The Landy-Szalay estimator for the two point correlation function of \( D \) measures the clustering signal in \( D \). \[ R402 \]

For example, given the position of two sets of objects,

• objects \( D \) (data) contains the clustering signal, and

• objects \( R \) (random) that contains no signal,

\[
\xi(r) = \frac{\langle D, D \rangle - 2 f \langle D, R \rangle + f^2 \langle R, R \rangle}{f^2 \langle R, R \rangle},
\]

where the brackets represents counting pairs between two data sets in a finite bin around \( r \) (distance), corresponding to setting cumulative=False, and \( f = \text{float(len}(D)) / \text{float(len}(R)) \) is the ratio between number of objects from data and random.

The algorithm implemented here is loosely based on the dual-tree algorithm described in \[ R401 \]. We switch between two different pair-cumulation scheme depending on the setting of cumulative. The computing time of the method we use when for cumulative == False does not scale with the total number of bins. The algorithm for cumulative == True scales linearly with the number of bins, though it is slightly faster when only 1 or 2 bins are used. \[ R405 \].

As an extension to the naive pair-counting, weighted pair-counting counts the product of weights instead of number of pairs. Weighted pair-counting is used to estimate marked correlation functions (\[ R403 \], section 2.2), or to properly calculate the average of data per distance bin (e.g. \[ R404 \], section 2.1 on redshift).

\textbf{cKDTree.query} (self, x,k=1,eps=0,p=2,distance_upper_bound=np.inf,n_jobs=1)

Query the kd-tree for nearest neighbors

Parameters x : array_like, last dimension self.m

An array of points to query.

k : list of integer or integer

The list of k-th nearest neighbors to return. If k is an integer it is treated as a list of [1, ... k] (range(1, k+1)). Note that the counting starts from 1.

eps : non-negative float

Return approximate nearest neighbors; the k-th returned value is guaranteed to be no further than \((1+eps)\) times the distance to the real k-th nearest neighbor.

p : float, 1<=p<=infinity
Which Minkowski p-norm to use. 1 is the sum-of-absolute-values “Manhattan” distance 2 is the usual Euclidean distance infinity is the maximum-coordinate-difference distance

**distance_upper_bound**: nonnegative float

Return only neighbors within this distance. This is used to prune tree searches, so if you are doing a series of nearest-neighbor queries, it may help to supply the distance to the nearest neighbor of the most recent point.

**n_jobs**: int, optional

Number of jobs to schedule for parallel processing. If -1 is given all processors are used. Default: 1.

**Returns**

- **d**: array of floats
  
The distances to the nearest neighbors. If x has shape \( \text{tuple}+(\text{self.m},) \), then d has shape \( \text{tuple}+(k,) \). When k == 1, the last dimension of the output is squeezed. Missing neighbors are indicated with infinite distances.

- **i**: ndarray of ints
  
The locations of the neighbors in self.data. If x has shape \( \text{tuple}+(\text{self.m},) \), then i has shape \( \text{tuple}+(k,) \). When k == 1, the last dimension of the output is squeezed. Missing neighbors are indicated with self.n.

**Notes**

If the KD-Tree is periodic, the position x is wrapped into the box.

When the input k is a list, a query for arange(max(k)) is performed, but only columns that store the requested values of k are preserved. This is implemented in a manner that reduces memory usage.

**Examples**

```python
>>> import numpy as np
>>> from scipy.spatial import cKDTree

>>> x, y = np.mgrid[0:5, 2:8]

>>> tree = cKDTree(np.c_[x.ravel(), y.ravel()])
```

To query the nearest neighbours and return squeezed result, use

```python
>>> dd, ii = tree.query([(0, 0), [2.1, 2.9]], k=1)

>>> print(dd, ii)

[[ 2.0 0.14142136]] [[ 0 13]]
```

To query the nearest neighbours and return unsqueezed result, use

```python
>>> dd, ii = tree.query([(0, 0), [2.1, 2.9]], k=[1])

>>> print(dd, ii)

[[ 2.0 0.14142136]] [[ 0]
[13]]
```

To query the second nearest neighbours and return unsqueezed result, use

```python
>>> dd, ii = tree.query([(0, 0), [2.1, 2.9]], k=[2])

>>> print(dd, ii)

[[ 2.23606798 0.90553851]] [[ 6]
[12]]
```
To query the first and second nearest neighbours, use

```python
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=2)
>>> print(dd, ii)
[[ 2.  2.23606798]
 [ 0.14142136  0.90553851]] [[ 0  6]
 [13 12]]
```
or, be more specific

```python
>>> dd, ii = tree.query([[0, 0], [2.1, 2.9]], k=[1, 2])
>>> print(dd, ii)
[[ 2.  2.23606798]
 [ 0.14142136  0.90553851]] [[ 0  6]
 [13 12]]
```

```
cKDTree.query_ball_point (self, x, r=2., eps=0)
```
Find all points within distance r of point(s) x.

**Parameters**

- x : array_like, shape tuple + (self.m,)
The point or points to search for neighbors of.
- r : positive float
  The radius of points to return.
- p : float, optional
  Which Minkowski p-norm to use. Should be in the range [1, inf].
- eps : nonnegative float, optional
  Approximate search. Branches of the tree are not explored if their nearest points are further than \( r / (1 + \text{eps}) \), and branches are added in bulk if their furthest points are nearer than \( r * (1 + \text{eps}) \).
- n_jobs : int, optional
  Number of jobs to schedule for parallel processing. If -1 is given all processors are used. Default: 1.

**Returns**

- results : list or array of lists
  If x is a single point, returns a list of the indices of the neighbors of x. If x is an array of points, returns an object array of shape tuple containing lists of neighbors.

**Notes**

If you have many points whose neighbors you want to find, you may save substantial amounts of time by putting them in a cKDTree and using query_ball_tree.

**Examples**

```python
>>> from scipy import spatial
>>> x, y = np.mgrid[0:4, 0:4]
>>> points = np.c_[x.ravel(), y.ravel()]
>>> tree = spatial.cKDTree(points)
>>> tree.query_ball_point([2, 0], 1)
[4, 8, 9, 12]
```

```
cKDTree.query_ball_tree (self, other, r=2., eps=0)
```
Find all pairs of points whose distance is at most r.

**Parameters**

- other : cKDTree instance
  The tree containing points to search against.
- r : float

---
The maximum distance, has to be positive.

\( p \): float, optional
Which Minkowski norm to use. \( p \) has to meet the condition \( 1 \leq p \leq \infty \).

\( \epsilon \): float, optional
Approximate search. Branches of the tree are not explored if their nearest points are further than \( r/(1+\epsilon) \), and branches are added in bulk if their furthest points are nearer than \( r \times (1+\epsilon) \). \( \epsilon \) has to be non-negative.

**Returns**

\( \text{results} \): list of lists
For each element \( \text{self.data}[i] \) of this tree, \( \text{results}[i] \) is a list of the indices of its neighbors in \( \text{other.data} \).

\[
cKDTree.query_pairs(\text{self}, r, p=2., \epsilon=0)
\]
Find all pairs of points whose distance is at most \( r \).

**Parameters**

\( r \): positive float
The maximum distance.

\( p \): float, optional
Which Minkowski norm to use. \( p \) has to meet the condition \( 1 \leq p \leq \infty \).

\( \epsilon \): float, optional
Approximate search. Branches of the tree are not explored if their nearest points are further than \( r/(1+\epsilon) \), and branches are added in bulk if their furthest points are nearer than \( r \times (1+\epsilon) \). \( \epsilon \) has to be non-negative.

\( \text{output_type} \): string, optional
Choose the output container, ‘set’ or ‘ndarray’. Default: ‘set’

\( \text{results} \): set or ndarray
Set of pairs \((i,j)\), with \( i < j \), for which the corresponding positions are close. If \( \text{output_type} \) is ‘ndarray’, an ndarray is returned instead of a set.

\[
cKDTree.sparse_distance_matrix(\text{self}, \text{other}, \text{max_distance}, p=2.)
\]
Compute a sparse distance matrix

Computes a distance matrix between two cKDTrees, leaving as zero any distance greater than \( \text{max_distance} \).

**Parameters**

\( \text{other} \): cKDTree
\( \text{max_distance} \): positive float
\( p \): float, \( 1 \leq p \leq \infty \)
\( \text{output_type} \): string, optional
Which Minkowski p-norm to use.

\( \text{output_type} \): string, optional

\( \text{result} \): dok_matrix, coo_matrix, dict or ndarray
Sparse matrix representing the results in “dictionary of keys” format. If a dict is returned the keys are \((i,j)\) tuples of indices. If \( \text{output_type} \) is ‘ndarray’ a record array with fields ‘i’, ‘j’, and ‘k’ is returned.

**Distance computations** (**scipy.spatial.distance**)

**Function Reference**

Distance matrix computation from a collection of raw observation vectors stored in a rectangular array.
Pairwise distances between observations in n-dimensional space.

Computes distance between each pair of the two collections of inputs.

Converts a vector-form distance vector to a square-form distance matrix, and vice-versa.

Computes the directed Hausdorff distance between two N-D arrays.

**scipy.spatial.distance.pdist** $(X, \text{metric}='\text{euclidean}', \text{args}, \text{kwargs})$

Pairwise distances between observations in n-dimensional space.

See Notes for common calling conventions.

**Parameters**

- $X$: ndarray
  An m by n array of m original observations in an n-dimensional space.
- metric: str or function, optional
  The distance metric to use. The distance function can be 'braycurtis', 'canberra', 'chebyshev', 'cityblock', 'correlation', 'cosine', 'dice', 'eclidean', 'hamming', 'jaccard', 'kulsinski', 'mahalanobis', 'matching', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'yule'.
- *args: tuple
  Deprecated. Additional arguments should be passed as keyword arguments
- **kwargs: dict, optional
  Extra arguments to metric: refer to each metric documentation for a list of all possible arguments.
  Some possible arguments:
  - p: scalar
    The p-norm to apply for Minkowski, weighted and unweighted. Default: 2.
  - w: ndarray
    The weight vector for metrics that support weights (e.g., Minkowski).
  - V: ndarray
    The variance vector for standardized Euclidean. Default: var(X, axis=0, ddof=1)
  - VI: ndarray
    The inverse of the covariance matrix for Mahalanobis. Default: inv(cov(X.T)).T

**Returns**

- $Y$: ndarray
  Returns a condensed distance matrix $Y$. For each $i$ and $j$ (where $i < j < m$), where $m$ is the number of original observations. The metric $\text{dist}(u=X[i], v=X[j])$ is computed and stored in entry $ij$.

**See also:**

- squareform: converts between condensed distance matrices and square distance matrices.

**Notes**

See squareform for information on how to calculate the index of this entry or to convert the condensed distance matrix to a redundant square matrix.

The following are common calling conventions.
1. \( Y = pdist(X, 'euclidean') \)

Computes the distance between \( m \) points using Euclidean distance (2-norm) as the distance metric between the points. The points are arranged as \( m \) \( n \)-dimensional row vectors in the matrix \( X \).

2. \( Y = pdist(X, 'minkowski', p=2.) \)

Computes the distances using the Minkowski distance \( ||u - v||_p \) (p-norm) where \( p \geq 1 \).

3. \( Y = pdist(X, 'cityblock') \)

Computes the city block or Manhattan distance between the points.

4. \( Y = pdist(X, 'seuclidean', V=None) \)

Computes the standardized Euclidean distance. The standardized Euclidean distance between two \( n \)-vectors \( u \) and \( v \) is

\[
\sqrt{\frac{1}{n} \sum (u_i - v_i)^2 / V[i]}
\]

\( V \) is the variance vector; \( V[i] \) is the variance computed over all the \( i \)’th components of the points. If not passed, it is automatically computed.

5. \( Y = pdist(X, 'sqeuclidean') \)

Computes the squared Euclidean distance \( ||u - v||_2^2 \) between the vectors.

6. \( Y = pdist(X, 'cosine') \)

Computes the cosine distance between vectors \( u \) and \( v \),

\[
1 - \frac{u \cdot v}{||u||_2 ||v||_2}
\]

where \( ||*||_2 \) is the 2-norm of its argument \( * \), and \( u \cdot v \) is the dot product of \( u \) and \( v \).

7. \( Y = pdist(X, 'correlation') \)

Computes the correlation distance between vectors \( u \) and \( v \). This is

\[
1 - \frac{(u - \bar{u}) \cdot (v - \bar{v})}{||(u - \bar{u})||_2 ||(v - \bar{v})||_2}
\]

where \( \bar{v} \) is the mean of the elements of vector \( v \), and \( x \cdot y \) is the dot product of \( x \) and \( y \).

8. \( Y = pdist(X, 'hamming') \)

Computes the normalized Hamming distance, or the proportion of those vector elements between two \( n \)-vectors \( u \) and \( v \) which disagree. To save memory, the matrix \( X \) can be of type boolean.

9. \( Y = pdist(X, 'jaccard') \)

Computes the Jaccard distance between the points. Given two vectors, \( u \) and \( v \), the Jaccard distance is the proportion of those elements \( u[i] \) and \( v[i] \) that disagree.

10. \( Y = pdist(X, 'chebyshev') \)

Computes the Chebyshev distance between the points. The Chebyshev distance between two \( n \)-vectors \( u \) and \( v \) is the maximum norm-1 distance between their respective elements. More precisely, the distance is given by

\[
d(u, v) = \max_i |u_i - v_i|
\]

11. \( Y = pdist(X, 'canberra') \)

Computes the Canberra distance between the points. The Canberra distance between two points \( u \) and \( v \) is

\[
d(u, v) = \sum_i \frac{|u_i - v_i|}{|u_i| + |v_i|}
\]
12. \( Y = \text{pdist}(X, 'braycurtis') \)

Computes the Bray-Curtis distance between the points. The Bray-Curtis distance between two points \( u \) and \( v \) is

\[
d(u, v) = \frac{\sum_i |u_i - v_i|}{\sum_i |u_i + v_i|}
\]

13. \( Y = \text{pdist}(X, 'mahalanobis', VI=None) \)

Computes the Mahalanobis distance between the points. The Mahalanobis distance between two points \( u \) and \( v \) is \( \sqrt{(u - v)(1/V)(u - v)^T} \) where \( 1/V \) (the \( VI \) variable) is the inverse covariance. If \( VI \) is not None, \( VI \) will be used as the inverse covariance matrix.

14. \( Y = \text{pdist}(X, 'yule') \)

Computes the Yule distance between each pair of boolean vectors. (see yule function documentation)

15. \( Y = \text{pdist}(X, 'matching') \)

Synonym for 'hamming'.

16. \( Y = \text{pdist}(X, 'dice') \)

Computes the Dice distance between each pair of boolean vectors. (see dice function documentation)

17. \( Y = \text{pdist}(X, 'kulsinski') \)

Computes the Kulsinski distance between each pair of boolean vectors. (see kulsinski function documentation)

18. \( Y = \text{pdist}(X, 'rogerstanimoto') \)

Computes the Rogers-Tanimoto distance between each pair of boolean vectors. (see rogerstanimoto function documentation)

19. \( Y = \text{pdist}(X, 'russellrao') \)

Computes the Russell-Rao distance between each pair of boolean vectors. (see russellrao function documentation)

20. \( Y = \text{pdist}(X, 'sokalmichener') \)

Computes the Sokal-Michener distance between each pair of boolean vectors. (see sokalmichener function documentation)

21. \( Y = \text{pdist}(X, 'sokalsneath') \)

Computes the Sokal-Sneath distance between each pair of boolean vectors. (see sokalsneath function documentation)

22. \( Y = \text{pdist}(X, 'wminkowski', p=2, w=w) \)

Computes the weighted Minkowski distance between each pair of vectors. (see wminkowski function documentation)

23. \( Y = \text{pdist}(X, f) \)

Computes the distance between all pairs of vectors in \( X \) using the user supplied 2-arity function \( f \). For example, Euclidean distance between the vectors could be computed as follows:
dm = pdist(X, \texttt{lambda } \textit{u, v: np.sqrt(((u-v)**2).sum())})

Note that you should avoid passing a reference to one of the distance functions defined in this library. For example,:

\[
dm = \text{pdist}(X, \text{\tt sokalsneath})
\]

would calculate the pair-wise distances between the vectors in X using the Python function sokalsneath. This would result in sokalsneath being called \((\binom{n}{2})\) times, which is inefficient. Instead, the optimized C version is more efficient, and we call it using the following syntax:

\[
dm = \text{pdist}(X, \text{\tt 'sokalsneath'})
\]

\[
\text{scipy.spatial.distance.cdist} \ (XA, XB, \text{\tt metric='euclidean', } *\text{args}, **\text{kwargs})
\]

Computes distance between each pair of the two collections of inputs.

See Notes for common calling conventions.

**Parameters**

- **XA**: ndarray
  - An \(m_A\) by \(n\) array of \(m_A\) original observations in an \(n\)-dimensional space. Inputs are converted to float type.
- **XB**: ndarray
  - An \(m_B\) by \(n\) array of \(m_B\) original observations in an \(n\)-dimensional space. Inputs are converted to float type.
- **metric**: str or callable, optional
- ***args**: tuple. Deprecated.
  - Additional arguments should be passed as keyword arguments
- ****kwargs**: dict, optional
  - Extra arguments to **metric**: refer to each metric documentation for a list of all possible arguments.
  - Some possible arguments:
    - \(p\): scalar The \(p\)-norm to apply for Minkowski, weighted and unweighted. Default: 2.
    - \(w\): ndarray The weight vector for metrics that support weights (e.g., Minkowski).
    - \(V\): ndarray The variance vector for standardized Euclidean. Default: \text{var(vstack([XA, XB]), axis=0, ddof=1)}
    - \(VI\): ndarray The inverse of the covariance matrix for Mahalanobis. Default: \text{inv(cov(vstack([XA, XB].T))).T}
    - \(out\): ndarray The output array If not None, the distance matrix \(Y\) is stored in this array. Note: metric independent, it will become a regular keyword
      arg in a future scipy version

**Returns**

- **Y**: ndarray
  - A \(m_A\) by \(m_B\) distance matrix is returned. For each \(i\) and \(j\), the metric
    \[
    \text{dist}(u=XA[i], \ v=XB[j])
    \]
    is computed and stored in the \(ij\) th entry.

**Raises**

- **ValueError**
  - An exception is thrown if \(XA\) and \(XB\) do not have the same number of columns.

**Notes**

The following are common calling conventions:
1. \( Y = \text{cdist}(X_A, X_B, \text{'}euclidean\text{'}) \)

Computes the distance between \( m \) points using Euclidean distance (2-norm) as the distance metric between the points. The points are arranged as \( m \ n \)-dimensional row vectors in the matrix \( X \).

2. \( Y = \text{cdist}(X_A, X_B, \text{'}minkowski\text{'}, p=2.) \)

Computes the distances using the Minkowski distance \(||u - v||_p\) (\( p \)-norm) where \( p \geq 1 \).

3. \( Y = \text{cdist}(X_A, X_B, \text{'}cityblock\text{')}) \)

Computes the city block or Manhattan distance between the points.

4. \( Y = \text{cdist}(X_A, X_B, \text{'}seuclidean\text{'}, V=None) \)

Computes the standardized Euclidean distance. The standardized Euclidean distance between two \( n \)-vectors \( u \) and \( v \) is

\[
\sqrt{\sum (u_i - v_i)^2 / V[i]}.
\]

\( V \) is the variance vector; \( V[i] \) is the variance computed over all the \( i \)'th components of the points. If not passed, it is automatically computed.

5. \( Y = \text{cdist}(X_A, X_B, \text{'}sjeuclidean\text{')}) \)

Computes the squared Euclidean distance \(||u - v||_2^2\) between the vectors.

6. \( Y = \text{cdist}(X_A, X_B, \text{'}cosine\text{')}) \)

Computes the cosine distance between vectors \( u \) and \( v \),

\[
1 - \frac{u \cdot v}{||u||_2 ||v||_2}
\]

where \( ||*||_2 \) is the 2-norm of its argument \(*\), and \( u \cdot v \) is the dot product of \( u \) and \( v \).

7. \( Y = \text{cdist}(X_A, X_B, \text{'}correlation\text{'}) \)

Computes the correlation distance between vectors \( u \) and \( v \). This is

\[
1 - \frac{(u - \bar{u}) \cdot (v - \bar{v})}{||(u - \bar{u})||_2 ||(v - \bar{v})||_2}
\]

where \( \bar{v} \) is the mean of the elements of vector \( v \), and \( x \cdot y \) is the dot product of \( x \) and \( y \).

8. \( Y = \text{cdist}(X_A, X_B, \text{'}hamming\text{'}) \)

Computes the normalized Hamming distance, or the proportion of those vector elements between two \( n \)-vectors \( u \) and \( v \) which disagree. To save memory, the matrix \( X \) can be of type boolean.

9. \( Y = \text{cdist}(X_A, X_B, \text{'}jaccard\text{'}) \)

Computes the Jaccard distance between the points. Given two vectors, \( u \) and \( v \), the Jaccard distance is the proportion of those elements \( u[i] \) and \( v[i] \) that disagree where at least one of them is non-zero.

10. \( Y = \text{cdist}(X_A, X_B, \text{'}chebyshev\text{'}) \)

Computes the Chebyshev distance between the points. The Chebyshev distance between two \( n \)-vectors \( u \) and \( v \) is the maximum norm-1 distance between their respective elements. More precisely, the distance is given by

\[
d(u,v) = \max_i |u_i - v_i|.
\]

11. \( Y = \text{cdist}(X_A, X_B, \text{'}canberra\text{'}) \)

Computes the Canberra distance between the points. The Canberra distance between two points \( u \) and \( v \) is

\[
d(u,v) = \sum_i \frac{|u_i - v_i|}{|u_i| + |v_i|}.
\]
12. \( Y = \text{cdist}(XA, XB, 'braycurtis') \)

Computes the Bray-Curtis distance between the points. The Bray-Curtis distance between two points \( u \) and \( v \) is

\[
d(u, v) = \frac{\sum_i(|u_i - v_i|)}{\sum_i(|u_i + v_i|)}
\]

13. \( Y = \text{cdist}(XA, XB, 'mahalanobis', VI=None) \)

Computes the Mahalanobis distance between the points. The Mahalanobis distance between two points \( u \) and \( v \) is \( \sqrt{(u - v)(1/V)(u - v)^T} \) where \( (1/V) \) (the \( VI \) variable) is the inverse covariance. If \( VI \) is not None, \( VI \) will be used as the inverse covariance matrix.

14. \( Y = \text{cdist}(XA, XB, 'yule') \)

Computes the Yule distance between the boolean vectors. (see \texttt{yule} function documentation)

15. \( Y = \text{cdist}(XA, XB, 'matching') \)

Synonym for 'hamming'.

16. \( Y = \text{cdist}(XA, XB, 'dice') \)

Computes the Dice distance between the boolean vectors. (see \texttt{dice} function documentation)

17. \( Y = \text{cdist}(XA, XB, 'kulsinski') \)

Computes the Kulinski distance between the boolean vectors. (see \texttt{kulsinski} function documentation)

18. \( Y = \text{cdist}(XA, XB, 'rogerstanimoto') \)

Computes the Rogers-Tanimoto distance between the boolean vectors. (see \texttt{rogerstanimoto} function documentation)

19. \( Y = \text{cdist}(XA, XB, 'russellrao') \)

Computes the Russell-Rao distance between the boolean vectors. (see \texttt{russellrao} function documentation)

20. \( Y = \text{cdist}(XA, XB, 'sokalmichener') \)

Computes the Sokal-Michener distance between the boolean vectors. (see \texttt{sokalmichener} function documentation)

21. \( Y = \text{cdist}(XA, XB, 'sokalsneath') \)

Computes the Sokal-Sneath distance between the vectors. (see \texttt{sokalsneath} function documentation)

22. \( Y = \text{cdist}(XA, XB, 'wminkowski', p=2., w=w) \)

Computes the weighted Minkowski distance between the vectors. (see \texttt{wminkowski} function documentation)

23. \( Y = \text{cdist}(XA, XB, f) \)

Computes the distance between all pairs of vectors in \( X \) using the user supplied 2-arity function \( f \). For example, Euclidean distance between the vectors could be computed as follows:
```python
dm = cdist(XA, XB, lambda u, v: np.sqrt(((u-v)**2).sum()))
```

Note that you should avoid passing a reference to one of the distance functions defined in this library. For example:

```python
dm = cdist(XA, XB, sokalsneath)
```

would calculate the pair-wise distances between the vectors in X using the Python function `sokalsneath`. This would result in sokalsneath being called \( \binom{n}{2} \) times, which is inefficient. Instead, the optimized C version is more efficient, and we call it using the following syntax:

```python
dm = cdist(XA, XB, 'sokalsneath')
```

### Examples

Find the Euclidean distances between four 2-D coordinates:

```python
>>> from scipy.spatial import distance
>>> coords = [(35.0456, -85.2672),
           ... (35.1174, -89.9711),
           ... (35.9728, -83.9422),
           ... (36.1667, -86.7833)]
>>> distance.cdist(coords, coords, 'euclidean')
array([[ 0. , 4.7044, 1.6172, 1.8856],
       [ 4.7044, 0. , 6.0893, 3.3561],
       [ 1.6172, 6.0893, 0. , 2.8477],
       [ 1.8856, 3.3561, 2.8477, 0. ]])
```

Find the Manhattan distance from a 3-D point to the corners of the unit cube:

```python
>>> a = np.array([[0, 0, 0],
                ... [0, 0, 1],
                ... [0, 1, 0],
                ... [0, 1, 1],
                ... [1, 0, 0],
                ... [1, 0, 1],
                ... [1, 1, 0],
                ... [1, 1, 1]])
>>> b = np.array([[0.1, 0.2, 0.4]])
>>> distance.cdist(a, b, 'cityblock')
array([[ 0.7],
       [ 0.9],
       [ 1.3],
       [ 1.5],
       [ 1.5],
       [ 1.7],
       [ 2.1],
       [ 2.3]])
```

`scipy.spatial.distance.squareform(X, force='no', checks=True)`

Converts a vector-form distance vector to a square-form distance matrix, and vice-versa.

**Parameters**

- `X`: ndarray
  - Either a condensed or redundant distance matrix.
- `force`: str, optional
  - As with MATLAB(TM), if force is equal to 'tovector' or 'tomatrix', the input will be treated as a distance matrix or distance vector respectively.
checks : bool, optional
If set to False, no checks will be made for matrix symmetry nor zero diagonals. This is useful if it is known that $X - X.T1$ is small and $\text{diag}(X)$ is close to zero. These values are ignored any way so they do not disrupt the squareform transformation.

Returns

$Y$ : ndarray
If a condensed distance matrix is passed, a redundant one is returned, or if a redundant one is passed, a condensed distance matrix is returned.

Notes

1. $v = \text{squareform}(X)$

Given a square d-by-d symmetric distance matrix $X$, $v = \text{squareform}(X)$ returns a $d \times (d-1) / 2$ (or $\binom{n}{2}$) sized vector $v$.

$v[\binom{n}{2} - \binom{n-i}{2} + (j - i - 1)]$ is the distance between points $i$ and $j$. If $X$ is non-square or asymmetric, an error is returned.

2. $X = \text{squareform}(v)$

Given a $d \times (d-1) / 2$ sized $v$ for some integer $d \geq 2$ encoding distances as described, $X = \text{squareform}(v)$ returns a d by d distance matrix $X$. The $X[i, j]$ and $X[j, i]$ values are set to $v[\binom{n}{2} - \binom{n-i}{2} + (j - i - 1)]$ and all diagonal elements are zero.

In Scipy 0.19.0, $\text{squareform}$ stopped casting all input types to float64, and started returning arrays of the same dtype as the input.

 scipy.spatial.distance.directed_hausdorff ($u$, $v$, seed=0)

Computes the directed Hausdorff distance between two N-D arrays.

Distances between pairs are calculated using a Euclidean metric.

Parameters

$u$ : (M,N) ndarray
Input array.

$v$ : (O,N) ndarray
Input array.

seed : int or None
Local $\text{np.random.RandomState}$ seed. Default is 0, a random shuffling of $u$ and $v$ that guarantees reproducibility.

Returns

$d$ : double
The directed Hausdorff distance between arrays $u$ and $v$.

$\text{index}_1$ : int
Index of point contributing to Hausdorff pair in $u$.

$\text{index}_2$ : int
Index of point contributing to Hausdorff pair in $v$.

See also:

scipy.spatial.procrustes
Another similarity test for two data sets

Notes

Uses the early break technique and the random sampling approach described by [R44]. Although worst-case performance is $O(m \times o)$ (as with the brute force algorithm), this is unlikely in practice as the input data would have to require the algorithm to explore every single point interaction, and after the algorithm shuffles the input points at that. The best case performance is $O(m)$, which is satisfied by selecting an inner loop distance.
that is less than cmax and leads to an early break as often as possible. The authors have formally shown that the average runtime is closer to O(m).

New in version 0.19.0.

References

[R44]

Examples

Find the directed Hausdorff distance between two 2-D arrays of coordinates:

```python
>>> from scipy.spatial.distance import directed_hausdorff
>>> u = np.array([(1.0, 0.0),
...                (0.0, 1.0),
...                (-1.0, 0.0),
...                (0.0, -1.0)])
>>> v = np.array([(2.0, 0.0),
...                (0.0, 2.0),
...                (-2.0, 0.0),
...                (0.0, -4.0)])
```

```python
>>> directed_hausdorff(u, v)[0]
2.23606797749979
```

```python
>>> directed_hausdorff(v, u)[0]
3.0
```

Find the general (symmetric) Hausdorff distance between two 2-D arrays of coordinates:

```python
>>> max(directed_hausdorff(u, v)[0], directed_hausdorff(v, u)[0])
3.0
```

Find the indices of the points that generate the Hausdorff distance (the Hausdorff pair):

```python
>>> directed_hausdorff(v, u)[1:]
(3, 3)
```

Predicates for checking the validity of distance matrices, both condensed and redundant. Also contained in this module are functions for computing the number of observations in a distance matrix.

```python
is_valid_dm(D[, tol, throw, name, warning])
```

Returns True if input array is a valid distance matrix. Distance matrices must be 2-dimensional numpy arrays. They must have a zero-diagonal, and they must be symmetric.

```python
is_valid_y(y[, warning, throw, name])
```

Returns True if the input array is a valid condensed distance matrix.

```python
num_obs_dm(d)
```

Returns the number of original observations that correspond to a square, redundant distance matrix.

```python
num_obs_y(Y)
```

Returns the number of original observations that correspond to a condensed distance matrix.

```python
scipy.spatial.distance.is_valid_dm(D, tol=0.0, throw=False, name='D', warning=False)
```

Returns True if input array is a valid distance matrix.
The distance matrix should be symmetric. `tol` is the maximum difference between entries $ij$ and $ji$ for the distance metric to be considered symmetric.

An exception is thrown if the distance matrix passed is not valid.

The name of the variable to checked. This is useful if `throw` is set to True so the offending variable can be identified in the exception message when an exception is thrown.

Instead of throwing an exception, a warning message is raised.

True if the variable $D$ passed is a valid distance matrix.

Small numerical differences in $D$ and $D.T$ and non-zeroness of the diagonal are ignored if they are within the tolerance specified by `tol`.

Condensed distance matrices must be 1-dimensional numpy arrays. Their length must be a binomial coefficient $\binom{n}{2}$ for some positive integer $n$.

The condensed distance matrix.

Invokes a warning if the variable passed is not a valid condensed distance matrix. The warning message explains why the distance matrix is not valid. `name` is used when referencing the offending variable.

Throws an exception if the variable passed is not a valid condensed distance matrix.

Used when referencing the offending variable in the warning or exception message.

Returns the number of original observations that correspond to a square, redundant distance matrix.

The target distance matrix.

The number of observations in the redundant distance matrix.

Returns the number of original observations that correspond to a condensed distance matrix.

Condensed distance matrix.

The number of observations in the condensed distance matrix $Y$.

Distance functions between two numeric vectors $u$ and $v$. Computing distances over a large collection of vectors is inefficient for these functions. Use `pdist` for this purpose.

**scipy.spatial.distance.braycurtis**(u, v, w=None)

Computes the Bray-Curtis distance between two 1-D arrays.

Bray-Curtis distance is defined as

\[
\sum |u_i - v_i| / \sum |u_i + v_i|
\]

The Bray-Curtis distance is in the range [0, 1] if all coordinates are positive, and is undefined if the inputs are of length zero.

**Parameters**

- **u**: (N,) array_like
  - Input array.
- **v**: (N,) array_like
  - Input array.
- **w**: (N,) array_like, optional
  - The weights for each value in u and v. Default is None, which gives each value a weight of 1.0

**Returns**

- **braycurtis**: double
  - The Bray-Curtis distance between 1-D arrays u and v.

**scipy.spatial.distance.canberra**(u, v, w=None)

Computes the Canberra distance between two 1-D arrays.

The Canberra distance is defined as

\[
d(u, v) = \sum_i \frac{|u_i - v_i|}{|u_i| + |v_i|}
\]

**Parameters**

- **u**: (N,) array_like
  - Input array.
- **v**: (N,) array_like
  - Input array.
- **w**: (N,) array_like, optional
  - The weights for each value in u and v. Default is None, which gives each value a weight of 1.0

**Returns**

- **canberra**: double
  - The Canberra distance between vectors u and v.
Notes

When \(u[i] \text{ and } v[i]\) are 0 for given i, then the fraction \(0/0 = 0\) is used in the calculation.

```python
scipy.spatial.distance.chebyshev(u, v)
```

Computes the Chebyshev distance.

Computes the Chebyshev distance between two 1-D arrays \(u\) and \(v\), which is defined as

\[
\max_i |u_i - v_i|.
\]

**Parameters**
- \(u\) : (N,) array_like
  - Input vector.
- \(v\) : (N,) array_like
  - Input vector.

**Returns**
- \(\text{chebyshev}\) : double
  - The Chebyshev distance between vectors \(u\) and \(v\).

```python
scipy.spatial.distance.cityblock(u, v, w=None)
```

Computes the City Block (Manhattan) distance.

Computes the Manhattan distance between two 1-D arrays \(u\) and \(v\), which is defined as

\[
\sum_i |u_i - v_i|.
\]

**Parameters**
- \(u\) : (N,) array_like
  - Input array.
- \(v\) : (N,) array_like
  - Input array.
- \(w\) : (N,) array_like, optional
  - The weights for each value in \(u\) and \(v\). Default is None, which gives each value a weight of 1.0

**Returns**
- \(\text{cityblock}\) : double
  - The City Block (Manhattan) distance between vectors \(u\) and \(v\).

```python
scipy.spatial.distance.correlation(u, v, w=None, centered=True)
```

Computes the correlation distance between two 1-D arrays. The correlation distance between \(u\) and \(v\), is defined as

\[
1 - \frac{(u - \bar{u}) \cdot (v - \bar{v})}{\| (u - \bar{u}) \|_2 \| (v - \bar{v}) \|_2}
\]

where \(\bar{u}\) is the mean of the elements of \(u\) and \(x \cdot y\) is the dot product of \(x\) and \(y\).

**Parameters**
- \(u\) : (N,) array_like
  - Input array.
- \(v\) : (N,) array_like
  - Input array.
- \(w\) : (N,) array_like, optional
  - The weights for each value in \(u\) and \(v\). Default is None, which gives each value a weight of 1.0

**Returns**
- \(\text{correlation}\) : double
  - The correlation distance between 1-D array \(u\) and \(v\).

```python
scipy.spatial.distance.cosine(u, v, w=None)
```

Computes the Cosine distance between 1-D arrays. The Cosine distance between \(u\) and \(v\), is defined as

\[
1 - \frac{u \cdot v}{\|u\|_2 \|v\|_2}
\]

where \(u \cdot v\) is the dot product of \(u\) and \(v\).
**Parameters**

- **u**: (N,) array_like
  - Input array.
- **v**: (N,) array_like
  - Input array.
- **w**: (N,) array_like, optional
  - The weights for each value in u and v. Default is None, which gives each value a weight of 1.0

**Returns**

- **cosine**: double
  - The Cosine distance between vectors u and v.

```python
scipy.spatial.distance.euclidean(u, v, w=None)
```

- Computes the Euclidean distance between two 1-D arrays.

The Euclidean distance between 1-D arrays u and v, is defined as

\[
|u - v|_2 = \left( \sum (w_i(u_i - v_i)^2) \right)^{1/2}
\]

**Parameters**

- **u**: (N,) array_like
  - Input array.
- **v**: (N,) array_like
  - Input array.
- **w**: (N,) array_like, optional
  - The weights for each value in u and v. Default is None, which gives each value a weight of 1.0

**Returns**

- **euclidean**: double
  - The Euclidean distance between vectors u and v.

```python
scipy.spatial.distance.mahalanobis(u, v, VI)
```

- Computes the Mahalanobis distance between two 1-D arrays.

The Mahalanobis distance between 1-D arrays u and v, is defined as

\[
\sqrt{(u - v)^\top V^{-1}(u - v)}
\]

where V is the covariance matrix. Note that the argument VI is the inverse of V.

**Parameters**

- **u**: (N,) array_like
  - Input array.
- **v**: (N,) array_like
  - Input array.
- **VI**: ndarray
  - The inverse of the covariance matrix.

**Returns**

- **mahalanobis**: double
  - The Mahalanobis distance between vectors u and v.

```python
scipy.spatial.distance.minkowski(u, v, p=2, w=None)
```

- Computes the Minkowski distance between two 1-D arrays.

The Minkowski distance between 1-D arrays u and v, is defined as

\[
|u - v|_p = \left( \sum w_i|u_i - v_i|^p \right)^{1/p}.
\]

**Parameters**

- **u**: (N,) array_like
  - Input array.
- **v**: (N,) array_like
  - Input array.
p : int
The order of the norm of the difference $||u - v||_p$.

w : (N,) array_like, optional
The weights for each value in u and v. Default is None, which gives each value a weight of 1.0

Returns
minkowski : double
The Minkowski distance between vectors u and v.

scipy.spatial.distance.seuclidean(u, v, V)
Returns the standardized Euclidean distance between two 1-D arrays.

The standardized Euclidean distance between u and v.

Parameters
u : (N,) array_like
Input array.

v : (N,) array_like
Input array.

V : (N,) array_like
V is an 1-D array of component variances. It is usually computed among a larger collection vectors.

Returns
seuclidean : double
The standardized Euclidean distance between vectors u and v.

scipy.spatial.distance.sqeuclidean(u, v, w=None)
Computes the squared Euclidean distance between two 1-D arrays.

The squared Euclidean distance between u and v is defined as

$$||u - v||_2^2 = \left( \sum (w_i |(u_i - v_i)|^2) \right)$$

Parameters
u : (N,) array_like
Input array.

v : (N,) array_like
Input array.

w : (N,) array_like, optional
The weights for each value in u and v. Default is None, which gives each value a weight of 1.0

Returns
sqeuclidean : double
The squared Euclidean distance between vectors u and v.

scipy.spatial.distance.wminkowski(u, v, p, w)
Computes the weighted Minkowski distance between two 1-D arrays. The weighted Minkowski distance between u and v, defined as

$$\left( \sum (|w_i(u_i - v_i)|^p) \right)^{1/p}.$$  

Parameters
u : (N,) array_like
Input array.

v : (N,) array_like
Input array.

p : int
The order of the norm of the difference $||u - v||_p$.

w : (N,) array_like
The weight vector.

Returns
wminkowski : double
The weighted Minkowski distance between vectors u and v.
Notes

wminkowski is DEPRECATED. It implements a definition where weights are powered. It is recommended to use the weighted version of minkowski instead. This function will be removed in a future version of scipy.

Distance functions between two boolean vectors (representing sets) u and v. As in the case of numerical vectors, pdist is more efficient for computing the distances between all pairs.

</tbody>
</table>

scipy.spatial.distance.dice (u, v, w=None)
Computes the Dice dissimilarity between two boolean 1-D arrays.

The Dice dissimilarity between u and v, is

\[
\frac{c_{TF} + c_{FT}}{2c_{TT} + c_{FT} + c_{TF}}
\]

where \(c_{ij}\) is the number of occurrences of \(u[k] = i\) and \(v[k] = j\) for \(k < n\).

Parameters
- u : (N,) ndarray, bool
  Input 1-D array.
- v : (N,) ndarray, bool
  Input 1-D array.
- w : (N,) array_like, optional
  The weights for each value in u and v. Default is None, which gives each value a weight of 1.0

Returns
- dice : double
  The Dice dissimilarity between 1-D arrays u and v.

scipy.spatial.distance.hamming (u, v, w=None)
Computes the Hamming distance between two 1-D arrays.

The Hamming distance between 1-D arrays u and v, is simply the proportion of disagreeing components in u and v. If u and v are boolean vectors, the Hamming distance is

\[
\frac{c_{01} + c_{10}}{n}
\]

where \(c_{ij}\) is the number of occurrences of \(u[k] = i\) and \(v[k] = j\) for \(k < n\).

Parameters
- u : (N,) array_like
  Input array.
SciPy Reference Guide, Release 1.0.0

v : (N,) array_like
Input array.
w : (N,) array_like, optional
The weights for each value in u and v. Default is None, which gives each value a weight of 1.0

Returns

hamming : double
The Hamming distance between vectors u and v.

scipy.spatial.distance.jaccard(u, v, w=None)
Computes the Jaccard-Needham dissimilarity between two boolean 1-D arrays.
The Jaccard-Needham dissimilarity between 1-D boolean arrays u and v, is defined as

\[
\frac{c_{TF} + c_{FT}}{c_{TT} + c_{FT} + c_{TF}}
\]

where \( c_{ij} \) is the number of occurrences of \( u[k] = i \) and \( v[k] = j \) for \( k < n \).

Parameters

u : (N,) array_like, bool
Input array.
v : (N,) array_like, bool
Input array.
w : (N,) array_like, optional
The weights for each value in u and v. Default is None, which gives each value a weight of 1.0

Returns

jaccard : double
The Jaccard distance between vectors u and v.

scipy.spatial.distance.kulsinski(u, v, w=None)
Computes the Kulsinski dissimilarity between two boolean 1-D arrays.
The Kulsinski dissimilarity between two boolean 1-D arrays u and v, is defined as

\[
\frac{c_{TF} + c_{FT} - c_{TT} + n}{c_{FT} + c_{TF} + n}
\]

where \( c_{ij} \) is the number of occurrences of \( u[k] = i \) and \( v[k] = j \) for \( k < n \).

Parameters

u : (N,) array_like, bool
Input array.
v : (N,) array_like, bool
Input array.
w : (N,) array_like, optional
The weights for each value in u and v. Default is None, which gives each value a weight of 1.0

Returns

kulsinski : double
The Kulsinski distance between vectors u and v.

scipy.spatial.distance.rogerstanimoto(u, v, w=None)
Computes the Rogers-Tanimoto dissimilarity between two boolean 1-D arrays.
The Rogers-Tanimoto dissimilarity between two boolean 1-D arrays u and v, is defined as

\[
R \frac{c_{TT}}{c_{TT} + c_{FF} + R}
\]

where \( c_{ij} \) is the number of occurrences of \( u[k] = i \) and \( v[k] = j \) for \( k < n \) and \( R = 2(c_{TF} + c_{FT}) \).

Parameters

u : (N,) array_like, bool
Input array.
v : (N,) array_like, bool
Input array.
SciPy Reference Guide, Release 1.0.0

w : (N,) array_like, optional
The weights for each value in u and v. Default is None, which gives each value a weight of 1.0

Returns rogerstanimoto : double
The Rogers-Tanimoto dissimilarity between vectors u and v.

scipy.spatial.distance.russellrao(u, v, w=None)
Computes the Russell-Rao dissimilarity between two boolean 1-D arrays.
The Russell-Rao dissimilarity between two boolean 1-D arrays, u and v, is defined as

\[ \frac{n - c_{TT}}{n} \]

where \( c_{ij} \) is the number of occurrences of \( u[k] = i \) and \( v[k] = j \) for \( k < n \).

Parameters u : (N,) array_like, bool
Input array.
v : (N,) array_like, bool
Input array.
w : (N,) array_like, optional
The weights for each value in u and v. Default is None, which gives each value a weight of 1.0

Returns russellrao : double
The Russell-Rao dissimilarity between vectors u and v.

scipy.spatial.distance.sokalmichener(u, v, w=None)
Computes the Sokal-Michener dissimilarity between two boolean 1-D arrays.
The Sokal-Michener dissimilarity between boolean 1-D arrays u and v, is defined as

\[ \frac{R}{S + R} \]

where \( c_{ij} \) is the number of occurrences of \( u[k] = i \) and \( v[k] = j \) for \( k < n \), \( R = 2 * (c_{TF} + c_{FT}) \) and \( S = c_{FF} + c_{TT} \).

Parameters u : (N,) array_like, bool
Input array.
v : (N,) array_like, bool
Input array.
w : (N,) array_like, optional
The weights for each value in u and v. Default is None, which gives each value a weight of 1.0

Returns sokalmichener : double
The Sokal-Michener dissimilarity between vectors u and v.

scipy.spatial.distance.sokalsneath(u, v, w=None)
Computes the Sokal-Sneath dissimilarity between two boolean 1-D arrays.
The Sokal-Sneath dissimilarity between u and v, is defined as

\[ \frac{R}{c_{TT} + 2R} \]

where \( c_{ij} \) is the number of occurrences of \( u[k] = i \) and \( v[k] = j \) for \( k < n \) and \( R = 2(c_{TF} + c_{FT}) \).

Parameters u : (N,) array_like, bool
Input array.
v : (N,) array_like, bool
Input array.
w : (N,) array_like, optional
The weights for each value in $u$ and $v$. Default is None, which gives each value a weight of 1.0.

Returns

sokalsneath : double

The Sokal-Sneath dissimilarity between vectors $u$ and $v$.

SciPy Reference Guide, Release 1.0.0

scipy.spatial.distance.yule($u$, $v$, $w$=None)

Computes the Yule dissimilarity between two boolean 1-D arrays.

The Yule dissimilarity is defined as

$$R = \frac{c_{TF} * c_{FT} + R}{2}$$

where $c_{ij}$ is the number of occurrences of $u[k] = i$ and $v[k] = j$ for $k < n$ and $R = 2.0 * c_{TF} * c_{FT}$.

Parameters

$u$ : (N,) array_like, bool

Input array.

$v$ : (N,) array_like, bool

Input array.

$w$ : (N,) array_like, optional

The weights for each value in $u$ and $v$. Default is None, which gives each value a weight of 1.0.

Returns

yule : double

The Yule dissimilarity between vectors $u$ and $v$.

hamming also operates over discrete numerical vectors.

Functions

braycurtis($u$, $v$, $w$)

Computes the Bray-Curtis distance between two 1-D arrays.

callable((object) -> bool)

Return whether the object is callable (i.e., some kind of function).

canberra($u$, $v$, $w$)

Computes the Canberra distance between two 1-D arrays.

cdist($XA$, $XB$, [metric])

Computes distance between each pair of the two collections of inputs.

chebyshev($u$, $v$)

Computes the Chebyshev distance.

cityblock($u$, $v$, $w$)

Computes the City Block (Manhattan) distance.

correlation($u$, $v$, [w, centered])

Computes the correlation distance between two 1-D arrays.

cosine($u$, $v$, [w])

Computes the Cosine distance between 1-D arrays.

dice($u$, $v$, [w])

Computes the Dice dissimilarity between two boolean 1-D arrays.

directed_hausdorff($u$, $v$, [seed])

Computes the directed Hausdorff distance between two N-D arrays.

euclidean($u$, $v$, $w$)

Computes the Euclidean distance between two 1-D arrays.

hamming($u$, $v$, $w$)

Computes the Hamming distance between two 1-D arrays.

is_valid_dm($D$, [tol, throw, name, warning])

Returns True if input array is a valid distance matrix.

is_valid_y($y$, [warning, throw, name])

Returns True if the input array is a valid condensed distance matrix.

jaccard($u$, $v$, $w$)

Computes the Jaccard-Needham dissimilarity between two boolean 1-D arrays.

kulsinski($u$, $v$, $w$)

Computes the Kulsinski dissimilarity between two boolean 1-D arrays.

mahalanobis($u$, $v$, VI)

Computes the Mahalanobis distance between two 1-D arrays.

matching(*args, **kwds)

matching is deprecated!

**Classes**

- **MetricInfo**
  - **Attributes**
    - `partial(func, *args, **keywords)` - new function with partial application
    - `xrange(start, stop[, step])` -> xrange object

**class** `scipy.spatial.Rectangle(maxes, mins)`

Hyperrectangle class.

Represents a Cartesian product of intervals.

**Methods**

- `max_distance_point(x[, p])` Return the maximum distance between input and points in the hyperrectangle.
- `max_distance_rectangle(other[, p])` Compute the maximum distance between points in the two hyperrectangles.
- `min_distance_point(x[, p])` Return the minimum distance between input and points in the hyperrectangle.
Table 5.229 – continued from previous page

<table>
<thead>
<tr>
<th>Function</th>

</tr>
</tbody>
</table>

`Rectangle.max_distance_point(x, p=2.0)`

Return the maximum distance between input and points in the hyperrectangle.

Parameters:
- `x`: array_like  
  Input array.
- `p`: float, optional  
  Input.

`Rectangle.max_distance_rectangle(other, p=2.0)`

Compute the maximum distance between points in the two hyperrectangles.

Parameters:
- `other`: hyperrectangle  
  Input.
- `p`: float, optional  
  Input.

`Rectangle.min_distance_point(x, p=2.0)`

Return the minimum distance between input and points in the hyperrectangle.

Parameters:
- `x`: array_like  
  Input.
- `p`: float, optional  
  Input.

`Rectangle.min_distance_rectangle(other, p=2.0)`

Compute the minimum distance between points in the two hyperrectangles.

Parameters:
- `other`: hyperrectangle  
  Input.
- `p`: float  
  Input.

`Rectangle.split(d, split)`

Produce two hyperrectangles by splitting.

In general, if you need to compute maximum and minimum distances to the children, it can be done more efficiently by updating the maximum and minimum distances to the parent.

Parameters:
- `d`: int  
  Axis to split hyperrectangle along.
- `split`: float  
  Position along axis `d` to split at.

`Rectangle.volume()`

Total volume.

5.24.2 Delaunay Triangulation, Convex Hulls and Voronoi Diagrams

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Delaunay(points[, furthest_site, ...])</code></td>
<td>Delaunay tessellation in N dimensions.</td>
</tr>
<tr>
<td><code>ConvexHull(points[, incremental, qhull_options])</code></td>
<td>Convex hulls in N dimensions.</td>
</tr>
</tbody>
</table>

Continued on next page
class scipy.spatial.Delaunay(points, furthest_site=False, incremental=False, qhull_options=None)

Delaunay tesselation in N dimensions.

New in version 0.9.

Parameters:
- points : ndarray of floats, shape (npoints, ndim)
  Coordinates of points to triangulate
- furthest_site : bool, optional
  Whether to compute a furthest-site Delaunay triangulation. Default: False
  New in version 0.12.0.
- incremental : bool, optional
  Allow adding new points incrementally. This takes up some additional resources.
- qhull_options : str, optional
  Additional options to pass to Qhull. See Qhull manual for details. Option “Qt” is always enabled. Default: “Qbb Qc Qz Qx Q12” for ndim > 4 and “Qbb Qc Qz Q12” otherwise. Incremental mode omits “Qz”.
  New in version 0.12.0.

Raises:
- QhullError
  Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.
- ValueError
  Raised if an incompatible array is given as input.

Notes:
The tesselation is computed using the Qhull library Qhull library.

Note: Unless you pass in the Qhull option “QJ”, Qhull does not guarantee that each input point appears as a vertex in the Delaunay triangulation. Omitted points are listed in the coplanar attribute.

Examples:
Triangulation of a set of points:

```python
>>> points = np.array([[0, 0], [0, 1.1], [1, 0], [1, 1]])
>>> from scipy.spatial import Delaunay
>>> tri = Delaunay(points)
```

We can plot it:

```python
>>> import matplotlib.pyplot as plt
>>> plt.triplot(points[:,0], points[:,1], tri.simplices.copy())
>>> plt.plot(points[:,0], points[:,1], 'o')
>>> plt.show()
```
Point indices and coordinates for the two triangles forming the triangulation:

```python
>>> tri.simplices
array([[2, 3, 0],  # may vary
       [3, 1, 0]], dtype=int32)
```

Note that depending on how rounding errors go, the simplices may be in a different order than above.

```python
>>> points[tri.simplices]
array([[[ 1. , 0. ],  # may vary
        [ 1. , 1. ],
        [ 0. , 0. ]],
       [[ 1. , 1. ],
        [ 0. , 1.1],
        [ 0. , 0. ]]])
```

Triangle 0 is the only neighbor of triangle 1, and it’s opposite to vertex 1 of triangle 1:

```python
>>> tri.neighbors[1]
array([-1, 0, -1], dtype=int32)
>>> points[tri.simplices[1,1]]
array([ 0. , 1.1])
```

We can find out which triangle points are in:

```python
>>> p = np.array(((0.1, 0.2), (1.5, 0.5), (0.5, 1.05)))
>>> tri.find_simplex(p)
array([-1, -1, 1], dtype=int32)
```

The returned integers in the array are the indices of the simplex the corresponding point is in. If -1 is returned, the point is in no simplex. Be aware that the shortcut in the following example only works correctly for valid points as invalid points result in -1 which is itself a valid index for the last simplex in the list.

```python
>>> p_valids = np.array(((0.1, 0.2), (0.5, 1.05)))
>>> tri.simplices[tri.find_simplex(p_valids)]
array([[3, 1, 0],  # may vary
       [3, 1, 0]], dtype=int32)
```
We can also compute barycentric coordinates in triangle 1 for these points:

```python
>>> b = tri.transform[1,:2].dot(np.transpose(p - tri.transform[1,2]))
>>> np.c_[np.transpose(b), 1 - b.sum(axis=0)]
array([[ 0.1 , 0.09090909, 0.80909091],
      [ 1.5 , -0.90909091, 0.40909091],
      [ 0.5 , 0.5 , 0. ]])
```

The coordinates for the first point are all positive, meaning it is indeed inside the triangle. The third point is on a vertex, hence its null third coordinate.

**Attributes**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>transform</strong></td>
<td>Affine transform from x to the barycentric coordinates c.</td>

<td>Vertices of facets forming the convex hull of the point set.</td>
</tr>
<tr>
<td><strong>vertex_neighbor_vertices</strong></td>
<td>Neighboring vertices of vertices.</td>
</tr>
</tbody>
</table>

**Delaunay.transform**

Affine transform from x to the barycentric coordinates c.

*Type* | ndarray of double, shape (nsimplex, ndim+1, ndim)

This is defined by:

```
T c = x - r
```

At vertex j, c_j = 1 and the other coordinates zero.

For simplex i, `transform[i,:ndim,:ndim]` contains inverse of the matrix T, and `transform[i,ndim,:]` contains the vector r.

**Delaunay.vertex_to_simplex**

Lookup array, from a vertex, to some simplex which it is a part of.

*Type* | ndarray of int, shape (npoints,)

**Delaunay.convex_hull**

Vertices of facets forming the convex hull of the point set.

*Type* | ndarray of int, shape (nfaces, ndim)

The array contains the indices of the points belonging to the (N-1)-dimensional facets that form the convex hull of the triangulation.

**Note:** Computing convex hulls via the Delaunay triangulation is inefficient and subject to increased numerical instability. Use `ConvexHull` instead.

**Delaunay.vertex_neighbor_vertices**

Neighboring vertices of vertices.

Tuple of two ndarrays of int: (indptr, indices). The indices of neighboring vertices of vertex k are `indices[indptr[k]:indptr[k+1]]`. 
points (ndarray of double, shape (npoints, ndim)) Coordinates of input points.
simplices (ndarray of ints, shape (nsimplex, ndim+1)) Indices of the points forming the simplices in the triangulation. For 2-D, the points are oriented counterclockwise.
neighbors (ndarray of ints, shape (nsimplex, ndim+1)) Indices of neighbor simplices for each simplex. The kth neighbor is opposite to the kth vertex. For simplices at the boundary, -1 denotes no neighbor.
equations (ndarray of double, shape (nsimplex, ndim+2)) [normal, offset] forming the hyperplane equation of the facet on the paraboloid (see Qhull documentation for more).
paraboloid_scale, paraboloid_shift (float) Scale and shift for the extra paraboloid dimension (see Qhull documentation for more).
coplanar (ndarray of int, shape (ncoplanar, 3)) Indices of coplanar points and the corresponding indices of the nearest facet and the nearest vertex. Coplanar points are input points which were not included in the triangulation due to numerical precision issues. If option “Qc” is not specified, this list is not computed. .. versionadded:: 0.12.0
vertices Same as simplices, but deprecated.

Methods

```
add_points(points[, restart])  Process a set of additional new points.
close()  Finish incremental processing.
find_simplex(self, xi[, bruteforce, tol])  Find the simplices containing the given points.
lift_points(self, x)  Lift points to the Qhull paraboloid.
plane_distance(self, xi)  Compute hyperplane distances to the point xi from all simplices.
```

**Delaunay**: `.add_points(points, restart=False)`
Process a set of additional new points.

**Parameters**
- `points` : ndarray
  New points to add. The dimensionality should match that of the initial points.
- `restart` : bool, optional
  Whether to restart processing from scratch, rather than adding points incrementally.

**Raises**
- `QhullError`
  Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

**See also:**
- `close`

**Notes**
You need to specify `incremental=True` when constructing the object to be able to add points incrementally. Incremental addition of points is also not possible after `close` has been called.

**Delaunay**: `.close()`
Finish incremental processing.

Call this to free resources taken up by Qhull, when using the incremental mode. After calling this, adding more points is no longer possible.

**Delaunay**: `.find_simplex(self, xi[, bruteforce, tol=None])`
Find the simplices containing the given points.

**Parameters**
- `tri` : DelaunayInfo

5.24. Spatial algorithms and data structures (`scipy.spatial`) 1523
SciPy Reference Guide, Release 1.0.0

Delaunay triangulation

\[ \text{xi} : \text{ndarray of double, shape (..., ndim)} \]
Points to locate

\[ \text{bruteforce} : \text{bool, optional} \]
Whether to only perform a brute-force search

\[ \text{tol} : \text{float, optional} \]
Tolerance allowed in the inside-triangle check. Default is 100*\(\varepsilon\).

Returns

\[ \text{i} : \text{ndarray of int, same shape as xi} \]
Indices of simplices containing each point. Points outside the triangulation get the value -1.

Notes

This uses an algorithm adapted from Qhull’s \text{qh\_findbestfacet}, which makes use of the connection between a convex hull and a Delaunay triangulation. After finding the simplex closest to the point in N+1 dimensions, the algorithm falls back to directed search in N dimensions.

```
Delaunay.lift_points(self, x)
```

Lift points to the Qhull paraboloid.

```
Delaunay.plane_distance(self, xi)
```

Compute hyperplane distances to the point \(xi\) from all simplices.

class scipy.spatial.ConvexHull (points, incremental=False, qhull_options=None)

Convex hulls in N dimensions.

New in version 0.12.0.

Parameters

\[ \text{points} : \text{ndarray of floats, shape (npoints, ndim)} \]
Coordinates of points to construct a convex hull from

\[ \text{incremental} : \text{bool, optional} \]
Allow adding new points incrementally. This takes up some additional resources.

\[ \text{qhull_options} : \text{str, optional} \]
Additional options to pass to Qhull. See Qhull manual for details. (Default: “Qx” for ndim > 4 and “” otherwise) Option “Qt” is always enabled.

Raises

\[ \text{QhullError} \]
Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

\[ \text{ValueError} \]
Raised if an incompatible array is given as input.

Notes

The convex hull is computed using the Qhull library.

References

[Qhull]

Examples

Convex hull of a random set of points:

```python
>>> from scipy.spatial import ConvexHull
>>> points = np.random.rand(30, 2) # 30 random points in 2-D
>>> hull = ConvexHull(points)
```

Plot it:
We could also have directly used the vertices of the hull, which for 2-D are guaranteed to be in counterclockwise order:

```python
>>> plt.plot(points[hull.vertices,0], points[hull.vertices,1], 'r--', lw=2)
>>> plt.plot(points[hull.vertices[0],0], points[hull.vertices[0],1], 'ro')
>>> plt.show()
```

**Attributes**

- **points** *(ndarray of double, shape (npoints, ndim))* Coordinates of input points.
- **vertices** *(ndarray of ints, shape (nvertices,))* Indices of points forming the vertices of the convex hull. For 2-D convex hulls, the vertices are in counterclockwise order. For other dimensions, they are in input order.
- **simplices** *(ndarray of ints, shape (nfacet, ndim))* Indices of points forming the simplical facets of the convex hull.
- **neighbors** *(ndarray of ints, shape (nfacet, ndim))* Indices of neighbor facets for each facet. The kth neighbor is opposite to the kth vertex. -1 denotes no neighbor.
- **equations** *(ndarray of double, shape (nfacet, ndim+1))* [normal, offset] forming the hyperplane equation of the facet (see Qhull documentation for more).
- **coplanar** *(ndarray of int, shape (ncoplanar, 3))* Indices of coplanar points and the corresponding indices of the nearest facets and nearest vertex indices. Coplanar points are input points which were not included in the triangulation due to numerical precision issues. If option “Qc” is not specified, this list is not computed.
- **area** *(float)* Area of the convex hull
- **volume** *(float)* Volume of the convex hull

**Methods**
convexhull.add_points(points, restart=False)
Process a set of additional new points.

Parameters:
points : ndarray
New points to add. The dimensionality should match that of the initial points.
restart : bool, optional
Whether to restart processing from scratch, rather than adding points incrementally.

Raises:
QhullError
Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

Notes
You need to specify incremental=True when constructing the object to be able to add points incrementally. Incremental addition of points is also not possible after close has been called.

convexhull.close()
Finish incremental processing.
Call this to free resources taken up by Qhull, when using the incremental mode. After calling this, adding more points is no longer possible.

class scipy.spatial.Voronoi(points, furthest_site=False, incremental=False, qhull_options=None)
V oronoi diagrams in N dimensions.
New in version 0.12.0.

Parameters:
points : ndarray of floats, shape (npoints, ndim)
Coordinates of points to construct a convex hull from
furthest_site : bool, optional
Whether to compute a furthest-site Voronoi diagram. Default: False
incremental : bool, optional
Allow adding new points incrementally. This takes up some additional resources.
qhull_options : str, optional
Additional options to pass to Qhull. See Qhull manual for details. (Default: “Qbb Qc Qz Qx” for ndim > 4 and “Qbb Qc Qz” otherwise. Incremental mode omits “Qz”.)

Raises:
QhullError
Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.
ValueError
Raised if an incompatible array is given as input.

Notes
The Voronoi diagram is computed using the Qhull library.
Examples

Voronoi diagram for a set of point:

```python
>>> points = np.array([[0, 0], [0, 1], [0, 2], [1, 0], [1, 1], [1, 2],
                     [2, 0], [2, 1], [2, 2]])
>>> from scipy.spatial import Voronoi, voronoi_plot_2d
>>> vor = Voronoi(points)

Plot it:

```python
>>> import matplotlib.pyplot as plt
>>> voronoi_plot_2d(vor)
>>> plt.show()
```

The Voronoi vertices:

```python
>>> vor.vertices
array([[ 0.5, 0.5],
       [ 1.5, 0.5],
       [ 0.5, 1.5],
       [ 1.5, 1.5]])
```

There is a single finite Voronoi region, and four finite Voronoi ridges:

```python
>>> vor.regions
[[], [-1, 0], [-1, 1], [1, -1, 0], [3, -1, 2], [-1, 3], [-1, 2], [3, 2, 0, 1], [2,
  -1, 0], [3, -1, 1]]
```

The ridges are perpendicular between lines drawn between the following input points:

```python
>>> vor.ridge_vertices
[[-1, 0], [-1, 0], [-1, 1], [-1, 1], [0, 1], [-1, 3], [-1, 2], [2, 3], [-1, 3], [-
  1, 2], [0, 2], [1, 3]]
```
```
[3, 4],
[5, 8],

**Voronoi.add_points** *(points, restart=False)*

Process a set of additional new points.

**Parameters**

- **points** : ndarray
  New points to add. The dimensionality should match that of the initial points.
- **restart** : bool, optional
  Whether to restart processing from scratch, rather than adding points incrementally.

**Raises**

- **QhullError**
  Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

**See also:**

- close

**Notes**

You need to specify incremental=True when constructing the object to be able to add points incrementally. Incremental addition of points is also not possible after close has been called.

**Voronoi.close()**

Finish incremental processing.

Call this to free resources taken up by Qhull, when using the incremental mode. After calling this, adding more points is no longer possible.
class scipy.spatial.SphericalVoronoi(points, radius=None, center=None, threshold=1e-06)

Voronoi diagrams on the surface of a sphere.

New in version 0.18.0.

Parameters

points : ndarray of floats, shape (npoints, 3)
Coordinates of points to construct a spherical Voronoi diagram from

radius : float, optional
Radius of the sphere (Default: 1)

center : ndarray of floats, shape (3,)
Center of sphere (Default: origin)

threshold : float
Threshold for detecting duplicate points and mismatches between points and sphere parameters. (Default: 1e-06)

Raises

ValueError
If there are duplicates in points. If the provided radius is not consistent with points.

See also:

Voronoi
Conventional Voronoi diagrams in N dimensions.

Notes
The spherical Voronoi diagram algorithm proceeds as follows. The Convex Hull of the input points (generators) is calculated, and is equivalent to their Delaunay triangulation on the surface of the sphere [Caroli]. A 3D Delaunay tetrahedralization is obtained by including the origin of the coordinate system as the fourth vertex of each simplex of the Convex Hull. The circumcenters of all tetrahedra in the system are calculated and projected to the surface of the sphere, producing the Voronoi vertices. The Delaunay tetrahedralization neighbour information is then used to order the Voronoi region vertices around each generator. The latter approach is substantially less sensitive to floating point issues than angle-based methods of Voronoi region vertex sorting.

The surface area of spherical polygons is calculated by decomposing them into triangles and using L’Huilier’s Theorem to calculate the spherical excess of each triangle [Weisstein]. The sum of the spherical excesses is multiplied by the square of the sphere radius to obtain the surface area of the spherical polygon. For nearly-degenerate spherical polygons an area of approximately 0 is returned by default, rather than attempting the unstable calculation.

Empirical assessment of spherical Voronoi algorithm performance suggests quadratic time complexity (loglinear is optimal, but algorithms are more challenging to implement). The reconstitution of the surface area of the sphere, measured as the sum of the surface areas of all Voronoi regions, is closest to 100 % for larger (>> 10) numbers of generators.

</tr>
</tbody>
</table>
Methods

sort_vertices_of_regions() For each region in regions, it sorts the indices of the Voronoi vertices such that the resulting points are in a clockwise or counterclockwise order around the generator point.

SphericalVoronoi.sort_vertices_of_regions() For each region in regions, it sorts the indices of the Voronoi vertices such that the resulting points are in a clockwise or counterclockwise order around the generator point.

This is done as follows: Recall that the n-th region in regions surrounds the n-th generator in points and that the k-th Voronoi vertex in vertices is the projected circumcenter of the tetrahedron obtained by the k-th triangle in _tri.simplices (and the origin). For each region n, we choose the first triangle (=Voronoi vertex) in _tri.simplices and a vertex of that triangle not equal to the center n. These determine a unique neighbor of that triangle, which is then chosen as the second triangle. The second triangle will have a unique vertex not equal to the current vertex or the center. This determines a unique neighbor of the second triangle, which is then chosen as the third triangle and so forth. We proceed through all the triangles (=Voronoi vertices) belonging to the generator in points and obtain a sorted version of the vertices of its surrounding region.

class scipy.spatial.HalfspaceIntersection(halfspaces, interior_point, incremental=False, qhull_options=None)

Halfspace intersections in N dimensions.

New in version 0.19.0.

Parameters

- halfspaces: ndarray of floats, shape (nineq, ndim+1)
  Stacked Inequalities of the form Ax + b <= 0 in format [A; b]
- interior_point: ndarray of floats, shape (ndim,)
  Point clearly inside the region defined by halfspaces. Also called a feasible point, it can be obtained by linear programming.
- incremental: bool, optional
  Allow adding new halfspaces incrementally. This takes up some additional resources.
- qhull_options: str, optional
  Additional options to pass to Qhull. See Qhull manual for details. (Default: “Qx” for ndim > 4 and “” otherwise) Option “H” is always enabled.

Raises

- QhullError Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.
- ValueError Raised if an incompatible array is given as input.

Notes

The intersections are computed using the Qhull library. This reproduces the “qhalf” functionality of Qhull.

>>>
>>>

from scipy.spatial import HalfspaceIntersection
import numpy as np
halfspaces = np.array([[-1, 0., 0.],
[0., -1., 0.],
[2., 1., -4.],
[-0.5, 1., -2.]])
feasible_point = np.array([0.5, 0.5])
hs = HalfspaceIntersection(halfspaces, feasible_point)

Plot halfspaces as filled regions and intersection points:
>>>
>>>
>>>
>>>
>>>
>>>
>>>
>>>
>>>
>>>
>>>
...
...
...
...
...
...
...
...
...
>>>
>>>

import matplotlib.pyplot as plt
fig = plt.figure()
ax = fig.add_subplot('111', aspect='equal')
xlim, ylim = (-1, 3), (-1, 3)
ax.set_xlim(xlim)
ax.set_ylim(ylim)
x = np.linspace(-1, 3, 100)
symbols = ['-', '+', 'x', '*']
signs = [0, 0, -1, -1]
fmt = {"color": None, "edgecolor": "b", "alpha": 0.5}
for h, sym, sign in zip(halfspaces, symbols, signs):
hlist = h.tolist()
fmt["hatch"] = sym
if h[1]== 0:
ax.axvline(-h[2]/h[0], label='{}x+{}y+{}=0'.format(*hlist))
xi = np.linspace(xlim[sign], -h[2]/h[0], 100)
ax.fill_between(xi, ylim[0], ylim[1], **fmt)
else:
ax.plot(x, (-h[2]-h[0]*x)/h[1], label='{}x+{}y+{}=0'.format(*hlist))
ax.fill_between(x, (-h[2]-h[0]*x)/h[1], ylim[sign], **fmt)
x, y = zip(*hs.intersections)
ax.plot(x, y, 'o', markersize=8)

By default, qhull does not provide with a way to compute an interior point. This can easily be computed using
linear programming. Considering halfspaces of the form 𝐴𝑥 + 𝑏 ≤ 0, solving the linear program:
𝑚𝑎𝑥 𝑦
𝑠.𝑡.𝐴𝑥 + 𝑦||𝐴𝑖 || ≤ −𝑏
With 𝐴𝑖 being the rows of A, i.e. the normals to each plane.
Will yield a point x that is furthest inside the convex polyhedron. To be precise, it is the center of the largest
hypersphere of radius y inscribed in the polyhedron. This point is called the Chebyshev center of the polyhedron
(see [R395] 4.3.1, pp148-149). The equations outputted by Qhull are always normalized.

5.24. Spatial algorithms and data structures (scipy.spatial) 1533
Whether to restart processing from scratch, rather than adding halfspaces incrementally.

Raises QhullError

Raised when Qhull encounters an error condition, such as geometrical degeneracy when options to resolve are not enabled.

See also:

close

Notes

You need to specify incremental=True when constructing the object to be able to add halfspaces incrementally. Incremental addition of halfspaces is also not possible after close has been called.

HalfspaceIntersection.close()

Finish incremental processing.

Call this to free resources taken up by Qhull, when using the incremental mode. After calling this, adding more points is no longer possible.

5.24.3 Plotting Helpers

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>

</tr>
</tbody>
</table>

scipy.spatial.delaunay_plot_2d(tri, ax=None)

Plot the given Delaunay triangulation in 2-D

Parameters

- tri : scipy.spatial.Delaunay instance
  - Triangulation to plot
- ax : matplotlib.axes.Axes instance, optional
  - Axes to plot on

Returns

- fig : matplotlib.figure.Figure instance
  - Figure for the plot

See also:

Delaunay, matplotlib.pyplot.triplot

Notes

Requires Matplotlib.

scipy.spatial.convex_hull_plot_2d(hull, ax=None)

Plot the given convex hull diagram in 2-D

Parameters

- hull : scipy.spatial.ConvexHull instance
  - Convex hull to plot
- ax : matplotlib.axes.Axes instance, optional
  - Axes to plot on

Returns

- fig : matplotlib.figure.Figure instance
  - Figure for the plot

See also:

ConvexHull
Notes

Requires Matplotlib.

```
scipy.spatial.voronoi_plot_2d(vor, ax=None, **kw)
```

Plot the given Voronoi diagram in 2-D

**Parameters**

- `vor`: scipy.spatial.Voronoi instance
  Diagram to plot
- `ax`: matplotlib.axes.Axes instance, optional
  Axes to plot on
- `show_points`: bool, optional
  Add the Voronoi points to the plot.
- `show_vertices`: bool, optional
  Add the Voronoi vertices to the plot.
- `line_colors`: string, optional
  Specifies the line color for polygon boundaries
- `line_width`: float, optional
  Specifies the line width for polygon boundaries
- `line_alpha`: float, optional
  Specifies the line alpha for polygon boundaries

**Returns**

- `fig`: matplotlib.figure.Figure instance
  Figure for the plot

See also:

- Voronoi

Notes

Requires Matplotlib.

See also:

- Tutorial

### 5.24.4 Simplex representation

The simplices (triangles, tetrahedra, ...) appearing in the Delaunay tessellation (N-dim simplices), convex hull facets, and Voronoi ridges (N-1 dim simplices) are represented in the following scheme:

```
tess = Delaunay(points)
hull = ConvexHull(points)
voro = Voronoi(points)

# coordinates of the j-th vertex of the i-th simplex
tess.points[tess.simplices[i, j], :]  # tesselation element
hull.points[hull.simplices[i, j], :]  # convex hull facet
voro.vertices[voro.ridge_vertices[i, j], :]  # ridge between Voronoi cells
```

For Delaunay triangulations and convex hulls, the neighborhood structure of the simplices satisfies the condition:

```
tess.neighbors[i, j] is the neighboring simplex of the i-th simplex, opposite to the j-vertex. It is -1 in case of no neighbor.
```

Convex hull facets also define a hyperplane equation:

```
(hull.equations[i, :-1] * coord).sum() + hull.equations[i, -1] == 0
```
Similar hyperplane equations for the Delaunay triangulation correspond to the convex hull facets on the corresponding \( N+1 \) dimensional paraboloid.

The Delaunay triangulation objects offer a method for locating the simplex containing a given point, and barycentric coordinate computations.

**Functions**

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{tsearch(tri, xi)}</td>
<td>Find simplices containing the given points. This function does the same thing as \texttt{Delaunay.find_simplex}. New in version 0.9. See also: \texttt{Delaunay.find_simplex}.</td>
</tr>
<tr>
<td>\texttt{distance_matrix(x, y, p=2, threshold=1000000)}</td>
<td>Compute the distance matrix. Returns the matrix of all pair-wise distances.</td>
</tr>
<tr>
<td>\texttt{minkowski_distance(x, y, p=2)}</td>
<td>Compute the ( L^p ) distance between two arrays.</td>
</tr>
<tr>
<td>\texttt{minkowski_distance_p(x, y, p)}</td>
<td>Compute the p-th power of the ( L^p ) distance between two arrays.</td>
</tr>
<tr>
<td>\texttt{procrustes(data1, data2)}</td>
<td>Procrustes analysis, a similarity test for two data sets.</td>
</tr>
</tbody>
</table>

### scipy.spatial.\texttt{tsearch(tri, xi)}

Find simplices containing the given points. This function does the same thing as \texttt{Delaunay.find_simplex}. New in version 0.9.

**See also:**

\texttt{Delaunay.find_simplex}

### scipy.spatial.\texttt{distance_matrix(x, y, p=2, threshold=1000000)}

Compute the distance matrix.

Returns the matrix of all pair-wise distances.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>( x ) : (M, K) array_like</td>
<td>Matrix of M vectors in K dimensions.</td>
</tr>
<tr>
<td>( y ) : (N, K) array_like</td>
<td>Matrix of N vectors in K dimensions.</td>
</tr>
<tr>
<td>( p ) : float, 1 \leq p \leq \infty</td>
<td>Which Minkowski p-norm to use.</td>
</tr>
<tr>
<td>( \text{threshold} ) : positive int</td>
<td>If ( M \times N \times K &gt; \text{threshold} ), algorithm uses a Python loop instead of large temporary arrays.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Result</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \text{result} ) : (M, N) \text{ndarray}</td>
<td>Matrix containing the distance from every vector in ( x ) to every vector in ( y ).</td>
</tr>
</tbody>
</table>

### Examples

```
>>> from scipy.spatial import distance_matrix
>>> distance_matrix([[0,0],[0,1]], [[1,0],[1,1]])
array([[ 1. , 1.41421356],
       [ 1.41421356, 1. ]])
```

### scipy.spatial.\texttt{minkowski_distance(x, y, p=2)}

Compute the \( L^p \) distance between two arrays.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>( x ) : (M, K) array_like</td>
<td>Input array.</td>
</tr>
<tr>
<td>( y ) : (N, K) array_like</td>
<td>Input array.</td>
</tr>
<tr>
<td>( p ) : float, 1 \leq p \leq \infty</td>
<td></td>
</tr>
</tbody>
</table>
Which Minkowski p-norm to use.

Examples

```python
>>> from scipy.spatial import minkowski_distance
>>> minkowski_distance([[0,0],[0,0]], [[1,1],[0,1]])
array([ 1.41421356,  1.])
```

scipy.spatial.minkowski_distance_p(x, y, p=2)
Compute the p-th power of the L**p distance between two arrays.

For efficiency, this function computes the L**p distance but does not extract the pth root. If \( p \) is 1 or infinity, this is equal to the actual L**p distance.

**Parameters**
- \( x \): (M, K) array_like
  Input array.
- \( y \): (N, K) array_like
  Input array.
- \( p \): float, 1 <= \( p \) <= infinity
  Which Minkowski p-norm to use.

Examples

```python
>>> from scipy.spatial import minkowski_distance_p
>>> minkowski_distance_p([[0,0],[0,0]], [[1,1],[0,1]])
array([2, 1])
```

scipy.spatial.procrustes(data1, data2)
Procrustes analysis, a similarity test for two data sets.

Each input matrix is a set of points or vectors (the rows of the matrix). The dimension of the space is the number of columns of each matrix. Given two identically sized matrices, procrustes standardizes both such that:

- \( tr(AA^T) = 1 \).
- Both sets of points are centered around the origin.

Procrustes ([R410], [R411]) then applies the optimal transform to the second matrix (including scaling/dilation, rotations, and reflections) to minimize \( M^2 = \sum (data1 - data2)^2 \), or the sum of the squares of the pointwise differences between the two input datasets.

This function was not designed to handle datasets with different numbers of datapoints (rows). If two data sets have different dimensionality (different number of columns), simply add columns of zeros to the smaller of the two.

**Parameters**
- \( data1 \): array_like
  Matrix, n rows represent points in k (columns) space \( data1 \) is the reference data, after it is standardised, the data from \( data2 \) will be transformed to fit the pattern in \( data1 \) (must have >1 unique points).
- \( data2 \): array_like
  n rows of data in k space to be fit to \( data1 \). Must be the same shape (numrows, numcols) as \( data1 \) (must have >1 unique points).

**Returns**
- \( mtx1 \): array_like
  A standardized version of \( data1 \).
- \( mtx2 \): array_like
  The orientation of \( data2 \) that best fits \( data1 \). Centered, but not necessarily \( tr(AA^T) = 1 \).
- \( disparity \): float
  \( M^2 \) as defined above.

**Raises**
- ValueError
  If the input arrays are not two-dimensional. If the shape of the input arrays is different. If the input arrays have zero columns or zero rows.
See also:

- `scipy.linalg.orthogonal_procrustes`
- `scipy.spatial.distance.directed_hausdorff`

Another similarity test for two data sets

Notes

- The disparity should not depend on the order of the input matrices, but the output matrices will, as only the first output matrix is guaranteed to be scaled such that $\text{tr}(AA^T) = 1$.
- Duplicate data points are generally ok, duplicating a data point will increase its effect on the procrustes fit.
- The disparity scales as the number of points per input matrix.

References

[R410], [R411]

Examples

```python
>>> from scipy.spatial import procrustes

The matrix `b` is a rotated, shifted, scaled and mirrored version of `a` here:

```python
>>> a = np.array([[1, 3], [1, 2], [1, 1], [2, 1]], 'd')
>>> b = np.array([[4, -2], [4, -4], [4, -6], [2, -6]], 'd')
>>> mtx1, mtx2, disparity = procrustes(a, b)
>>> round(disparity)
0.0
```

5.25 Distance computations (`scipy.spatial.distance`)

5.25.1 Function Reference

Distance matrix computation from a collection of raw observation vectors stored in a rectangular array.

- `pdist(X[, metric])`: Pairwise distances between observations in n-dimensional space.
- `cdist(XA, XB[, metric])`: Computes distance between each pair of the two collections of inputs.
- `squareform(X[, force, checks])`: Converts a vector-form distance vector to a square-form distance matrix, and vice-versa.
- `directed_hausdorff(u, v[, seed])`: Computes the directed Hausdorff distance between two N-D arrays.

`scipy.spatial.distance.pdist(X, metric='euclidean', *args, **kwargs)`: Pairwise distances between observations in n-dimensional space.

See Notes for common calling conventions.

- **Parameters**
  - `X`: ndarray
    - An m by n array of m original observations in an n-dimensional space.
  - `metric`: str or function, optional

References

[R410], [R411]

*args : tuple. Deprecated.

Additional arguments should be passed as keyword arguments

**kwargs : dict, optional

Extra arguments to metric: refer to each metric documentation for a list of all possible arguments.

Some possible arguments:

- p : scalar The p-norm to apply for Minkowski, weighted and unweighted. Default: 2.
- w : ndarray The weight vector for metrics that support weights (e.g., Minkowski).
- V : ndarray The variance vector for standardized Euclidean. Default: var(X, axis=0, ddof=1)
- VI : ndarray The inverse of the covariance matrix for Mahalanobis. Default: inv(cov(X.T)).T

out : ndarray. The output array If not None, condensed distance matrix Y is stored in this array. Note: metric independent, it will become a regular keyword arg in a future scipy version

Returns

Y : ndarray

Returns a condensed distance matrix Y. For each i and j (where i < j < m), where m is the number of original observations. The metric dist(u=X[i], v=X[j]) is computed and stored in entry i j.

See also:

squareform converts between condensed distance matrices and square distance matrices.

Notes

See squareform for information on how to calculate the index of this entry or to convert the condensed distance matrix to a redundant square matrix.

The following are common calling conventions.

1. Y = pdist(X, 'euclidean')

Computes the distance between m points using Euclidean distance (2-norm) as the distance metric between the points. The points are arranged as m n-dimensional row vectors in the matrix X.

2. Y = pdist(X, 'minkowski', p=2.)

Computes the distances using the Minkowski distance \( ||u - v||_p \) (p-norm) where \( p \geq 1 \).

3. Y = pdist(X, 'cityblock')

Computes the city block or Manhattan distance between the points.

4. Y = pdist(X, 'seuclidean', V=None)

Computes the standardized Euclidean distance. The standardized Euclidean distance between two n-vectors u and v is

\[
\sqrt{\sum (u_i - v_i)^2 / V[x_i]}
\]

V is the variance vector; V[i] is the variance computed over all the i’th components of the points. If not passed, it is automatically computed.

5. Y = pdist(X, 'sqeuclidean')

Computes the squared Euclidean distance \( ||u - v||^2 \) between the vectors.
6. $Y = \text{pdist}(X, 'cosine')$

Computes the cosine distance between vectors $u$ and $v$,

$$1 - \frac{u \cdot v}{||u||_2 ||v||_2}$$

where $||*||_2$ is the 2-norm of its argument $*$, and $u \cdot v$ is the dot product of $u$ and $v$.

7. $Y = \text{pdist}(X, 'correlation')$

Computes the correlation distance between vectors $u$ and $v$. This is

$$1 - \frac{(u - \bar{u}) \cdot (v - \bar{v})}{||(u - \bar{u})||_2 ||(v - \bar{v})||_2}$$

where $\bar{v}$ is the mean of the elements of vector $v$, and $x \cdot y$ is the dot product of $x$ and $y$.

8. $Y = \text{pdist}(X, 'hamming')$

Computes the normalized Hamming distance, or the proportion of those vector elements between two $n$-vectors $u$ and $v$ which disagree. To save memory, the matrix $X$ can be of type boolean.

9. $Y = \text{pdist}(X, 'jaccard')$

Computes the Jaccard distance between the points. Given two vectors, $u$ and $v$, the Jaccard distance is the proportion of those elements $u[i]$ and $v[i]$ that disagree.

10. $Y = \text{pdist}(X, 'chebyshev')$

Computes the Chebyshev distance between the points. The Chebyshev distance between two $n$-vectors $u$ and $v$ is the maximum norm-1 distance between their respective elements. More precisely, the distance is given by

$$d(u, v) = \max_i |u_i - v_i|$$

11. $Y = \text{pdist}(X, 'canberra')$

Computes the Canberra distance between the points. The Canberra distance between two points $u$ and $v$ is

$$d(u, v) = \sum_i \frac{|u_i - v_i|}{|u_i| + |v_i|}$$

12. $Y = \text{pdist}(X, 'braycurtis')$

Computes the Bray-Curtis distance between the points. The Bray-Curtis distance between two points $u$ and $v$ is

$$d(u, v) = \sum \frac{|u_i - v_i|}{|u_i| + |v_i|}$$

13. $Y = \text{pdist}(X, 'mahalanobis', V=\text{None})$

Computes the Mahalanobis distance between the points. The Mahalanobis distance between two points $u$ and $v$ is $\sqrt{(u - v)(1/V)(u - v)^T}$ where $(1/V)$ (the $V$ variable) is the inverse covariance. If $V$ is not None, $V$ will be used as the inverse covariance matrix.

14. $Y = \text{pdist}(X, 'yule')$

Computes the Yule distance between each pair of boolean vectors. (see yule function documentation)

15. $Y = \text{pdist}(X, 'matching')$

Synonym for ‘hamming’.
16. \( Y = \text{pdist}(X, \ 'dice') \)
Computes the Dice distance between each pair of boolean vectors. (see dice function documentation)

17. \( Y = \text{pdist}(X, \ 'kulsinski') \)
Computes the Kulsinski distance between each pair of boolean vectors. (see kulsinski function documentation)

18. \( Y = \text{pdist}(X, \ 'rogerstanimoto') \)
Computes the Rogers-Tanimoto distance between each pair of boolean vectors. (see rogerstanimoto function documentation)

19. \( Y = \text{pdist}(X, \ 'russellrao') \)
Computes the Russell-Rao distance between each pair of boolean vectors. (see russellrao function documentation)

20. \( Y = \text{pdist}(X, \ 'sokalmichener') \)
Computes the Sokal-Michener distance between each pair of boolean vectors. (see sokalmichener function documentation)

21. \( Y = \text{pdist}(X, \ 'sokalsneath') \)
Computes the Sokal-Sneath distance between each pair of boolean vectors. (see sokalsneath function documentation)

22. \( Y = \text{pdist}(X, \ 'wminkowski', p=2, w=w) \)
Computes the weighted Minkowski distance between each pair of vectors. (see wminkowski function documentation)

23. \( Y = \text{pdist}(X, f) \)
Computes the distance between all pairs of vectors in X using the user supplied 2-arity function f. For example, Euclidean distance between the vectors could be computed as follows:

\[
\text{dm} = \text{pdist}(X, \ \text{lambda} \ u, v: \ \text{np.sqrt(((u-v)**2).sum()))}
\]

Note that you should avoid passing a reference to one of the distance functions defined in this library. For example,:

\[
\text{dm} = \text{pdist}(X, \ \text{sokalsneath})
\]
would calculate the pair-wise distances between the vectors in X using the Python function sokalsneath. This would result in sokalsneath being called \( \binom{n}{2} \) times, which is inefficient. Instead, the optimized C version is more efficient, and we call it using the following syntax.:

\[
\text{dm} = \text{pdist}(X, \ 'sokalsneath')
\]

\textbf{scipy.spatial.distance.cdist} \((XA, XB, metric='euclidean', *args, **kwargs)\)
Computes distance between each pair of the two collections of inputs.

See Notes for common calling conventions.

\textbf{Parameters}
\begin{itemize}
\item \textbf{XA} : ndarray
\end{itemize}
An \( m_A \) by \( n \) array of \( m_A \) original observations in an \( n \)-dimensional space. Inputs are converted to float type.
XB : ndarray
An \( m_B \) by \( n \) array of \( m_B \) original observations in an \( n \)-dimensional space. Inputs are converted to float type.

metric : str or callable, optional

*args : tuple. Deprecated.
Additional arguments should be passed as keyword arguments

**kwargs : dict, optional
Extra arguments to metric: refer to each metric documentation for a list of all possible arguments.
Some possible arguments:
p : scalar The p-norm to apply for Minkowski, weighted and unweighted. Default: 2.
w : ndarray The weight vector for metrics that support weights (e.g., Minkowski).
V : ndarray The weight vector for standardized Euclidean. Default: var(vstack([XA, XB]), axis=0, ddof=1)
VI : ndarray The inverse of the covariance matrix for Mahalanobis. Default: inv(cov(vstack([XA, XB].T))).T
out : ndarray The output array If not None, the distance matrix Y is stored in this array. Note: metric independent, it will become a regular keyword arg in a future scipy version

Returns
Y : ndarray
A \( m_A \) by \( m_B \) distance matrix is returned. For each \( i \) and \( j \), the metric \( \text{dist}(u=XA[i], v=XB[j]) \) is computed and stored in the \( ij \) th entry.

Raises
ValueError
An exception is thrown if \( XA \) and \( XB \) do not have the same number of columns.

Notes
The following are common calling conventions:
1. \( Y = cdist(XA, XB, 'euclidean') \)
Computes the distance between \( m \) points using Euclidean distance (2-norm) as the distance metric between the points. The points are arranged as \( m \) \( n \)-dimensional row vectors in the matrix \( X \).

2. \( Y = cdist(XA, XB, 'minkowski', p=2.) \)
Computes the distances using the Minkowski distance \( ||u - v||_p \) (p-norm) where \( p \geq 1 \).

3. \( Y = cdist(XA, XB, 'cityblock') \)
Computes the city block or Manhattan distance between the points.

4. \( Y = cdist(XA, XB, 'seuclidean', V=None) \)
Computes the standardized Euclidean distance. The standardized Euclidean distance between two \( n \)-vectors \( u \) and \( v \) is

\[
\sqrt{\sum (u_i - v_i)^2 / V[x_i]}.
\]

\( V \) is the variance vector; \( V[i] \) is the variance computed over all the \( i \)’th components of the points. If not passed, it is automatically computed.

5. \( Y = cdist(XA, XB, 'sqeuclidean') \)
Computes the squared Euclidean distance \( ||u - v||_2^2 \) between the vectors.
6. \( Y = \text{cdist}(XA, XB, \text{'cosine'}) \)

Computes the cosine distance between vectors \( u \) and \( v \),
\[
1 - \frac{u \cdot v}{||u||_2||v||_2}
\]
where \( ||*||_2 \) is the 2-norm of its argument *, and \( u \cdot v \) is the dot product of \( u \) and \( v \).

7. \( Y = \text{cdist}(XA, XB, \text{'correlation'}) \)

Computes the correlation distance between vectors \( u \) and \( v \). This is
\[
1 - \frac{(u - \bar{u}) \cdot (v - \bar{v})}{||(u - \bar{u})||_2||(v - \bar{v})||_2}
\]
where \( \bar{v} \) is the mean of the elements of vector \( v \), and \( x \cdot y \) is the dot product of \( x \) and \( y \).

8. \( Y = \text{cdist}(XA, XB, \text{'hamming'}) \)

Computes the normalized Hamming distance, or the proportion of those vector elements between two n-vectors \( u \) and \( v \) which disagree. To save memory, the matrix \( X \) can be of type boolean.

9. \( Y = \text{cdist}(XA, XB, \text{'jaccard'}) \)

Computes the Jaccard distance between the points. Given two vectors, \( u \) and \( v \), the Jaccard distance is the proportion of those elements \( u[i] \) and \( v[i] \) that disagree where at least one of them is non-zero.

10. \( Y = \text{cdist}(XA, XB, \text{'chebyshev'}) \)

Computes the Chebyshev distance between the points. The Chebyshev distance between two n-vectors \( u \) and \( v \) is the maximum norm-1 distance between their respective elements. More precisely, the distance is given by
\[
d(u, v) = \max_i |u_i - v_i|.
\]

11. \( Y = \text{cdist}(XA, XB, \text{'canberra'}) \)

Computes the Canberra distance between the points. The Canberra distance between two points \( u \) and \( v \) is
\[
d(u, v) = \sum_i \frac{|u_i - v_i|}{|u_i| + |v_i|}.
\]

12. \( Y = \text{cdist}(XA, XB, \text{'braycurtis'}) \)

Computes the Bray-Curtis distance between the points. The Bray-Curtis distance between two points \( u \) and \( v \) is
\[
d(u, v) = \frac{\sum_i (|u_i - v_i|)}{\sum_i (|u_i + v_i|)}
\]

13. \( Y = \text{cdist}(XA, XB, \text{'mahalanobis'}, \text{VI=None}) \)

Computes the Mahalanobis distance between the points. The Mahalanobis distance between two points \( u \) and \( v \) is \( \sqrt{(u - v)(1/V)(u - v)^T} \) where \( (1/V) \) (the VI variable) is the inverse covariance. If \( VI \) is not None, \( VI \) will be used as the inverse covariance matrix.

14. \( Y = \text{cdist}(XA, XB, \text{'yule'}) \)

Computes the Yule distance between the boolean vectors. (see \text{yule} function documentation)

15. \( Y = \text{cdist}(XA, XB, \text{'matching'}) \)

Synonym for ‘hamming’.
16. \[ Y = \text{cdist}(X_A, X_B, 'dice') \]

Computes the Dice distance between the boolean vectors. (see dice function documentation)

17. \[ Y = \text{cdist}(X_A, X_B, 'kulsinski') \]

Computes the Kulinski distance between the boolean vectors. (see kulsinski function documentation)

18. \[ Y = \text{cdist}(X_A, X_B, 'rogerstanimoto') \]

Computes the Rogers-Tanimoto distance between the boolean vectors. (see rogerstanimoto function documentation)

19. \[ Y = \text{cdist}(X_A, X_B, 'russellrao') \]

Computes the Russell-Rao distance between the boolean vectors. (see russellrao function documentation)

20. \[ Y = \text{cdist}(X_A, X_B, 'sokalmichener') \]

Computes the Sokal-Michener distance between the boolean vectors. (see sokalmichener function documentation)

21. \[ Y = \text{cdist}(X_A, X_B, 'sokalsneath') \]

Computes the Sokal-Sneath distance between the vectors. (see sokalsneath function documentation)

22. \[ Y = \text{cdist}(X_A, X_B, 'wminkowski', p=2., w=w) \]

Computes the weighted Minkowski distance between the vectors. (see wminkowski function documentation)

23. \[ Y = \text{cdist}(X_A, X_B, f) \]

Computes the distance between all pairs of vectors in \(X\) using the user supplied 2-arity function \(f\). For example, Euclidean distance between the vectors could be computed as follows:

\[
\begin{align*}
\text{dm} &= \text{dist}(X_A, X_B, \text{lambda } u, v: \text{np.sqrt}(((u-v)**2).\text{sum}()))
\end{align*}
\]

Note that you should avoid passing a reference to one of the distance functions defined in this library. For example:

\[
\begin{align*}
\text{dm} &= \text{dist}(X_A, X_B, \text{sokalsneath})
\end{align*}
\]

would calculate the pair-wise distances between the vectors in \(X\) using the Python function sokalsneath. This would result in sokalsneath being called \(n^2\) times, which is inefficient. Instead, the optimized C version is more efficient, and we call it using the following syntax:

\[
\begin{align*}
\text{dm} &= \text{dist}(X_A, X_B, 'sokalsneath')
\end{align*}
\]

**Examples**

Find the Euclidean distances between four 2-D coordinates:

```python
>>> from scipy.spatial import distance

>>> coords = [(35.0456, -85.2672),
            ..., (35.1174, -89.9711),
            ..., (35.9728, -83.9422),
            ..., (36.1667, -86.7833)]
```
Find the Manhattan distance from a 3-D point to the corners of the unit cube:

```python
>>> a = np.array([[0, 0, 0],
    ... [0, 0, 1],
    ... [0, 1, 0],
    ... [0, 1, 1],
    ... [1, 0, 0],
    ... [1, 0, 1],
    ... [1, 1, 0],
    ... [1, 1, 1]])
>>> b = np.array([[0.1, 0.2, 0.4]])
>>> distance.cdist(a, b, 'cityblock')
array([[ 0.7],
    [ 0.9],
    [ 1.3],
    [ 1.5],
    [ 1.5],
    [ 1.7],
    [ 2.1],
    [ 2.3]])
```

SciPy Reference Guide, Release 1.0.0

SciPy Reference Guide, Release 1.0.0

```python
>>> distance.cdist(coords, coords, 'euclidean')
array([[ 0. , 4.7044, 1.6172, 1.8856],
    [ 4.7044, 0. , 6.0893, 3.3561],
    [ 1.6172, 6.0893, 0. , 2.8477],
    [ 1.8856, 3.3561, 2.8477, 0. ]])
```

**scipy.spatial.distance.squareform**(X, force='no', checks=True)

Converts a vector-form distance vector to a square-form distance matrix, and vice-versa.

**Parameters**

- **X**: ndarray
  - Either a condensed or redundant distance matrix.
- **force**: str, optional
  - As with MATLAB(TM), if force is equal to 'tovector' or 'tomatrix', the input will be treated as a distance matrix or distance vector respectively.
- **checks**: bool, optional
  - If set to False, no checks will be made for matrix symmetry nor zero diagonals. This is useful if it is known that \( X - X^T \) is small and \( \text{diag}(X) \) is close to zero. These values are ignored any way so they do not disrupt the squareform transformation.

**Returns**

- **Y**: ndarray
  - If a condensed distance matrix is passed, a redundant one is returned, or if a redundant one is passed, a condensed distance matrix is returned.

**Notes**

1. \( v = \text{squareform}(X) \)
   - Given a square \( d \)-by-\( d \) symmetric distance matrix \( X \), \( v = \text{squareform}(X) \) returns a \( d \times (d-1) / 2 \) or \( \binom{d}{2} \) sized vector \( v \).
   - \( v[i(\binom{d}{2}) + (n-i) + (j-i-1)] \) is the distance between points \( i \) and \( j \). If \( X \) is non-square or asymmetric, an error is returned.
2. \( X = \text{squareform}(v) \)
Given a \(d \times (d-1)/2\) sized \(v\) for some integer \(d \geq 2\) encoding distances as described, \(X = \text{squareform}(v)\) returns a \(d \times d\) distance matrix \(X\). The \(X[i, j]\) and \(X[j, i]\) values are set to \(v[{n \choose 2} - {n-i \choose 2} + (j - i - 1)]\) and all diagonal elements are zero.

In Scipy 0.19.0, \texttt{squareform} stopped casting all input types to float64, and started returning arrays of the same dtype as the input.

\texttt{scipy.spatial.distance.directed_hausdorff}(u, v, seed=0)

Computes the directed Hausdorff distance between two N-D arrays.

Distances between pairs are calculated using a Euclidean metric.

**Parameters**

- \(u\) : (M,N) ndarray
  Input array.
- \(v\) : (O,N) ndarray
  Input array.
- \(seed\) : int or None
  Local \texttt{np.random.RandomState} seed. Default is 0, a random shuffling of \(u\) and \(v\) that guarantees reproducibility.

**Returns**

- \(d\) : double
  The directed Hausdorff distance between arrays \(u\) and \(v\),
- \(index_1\) : int
  Index of point contributing to Hausdorff pair in \(u\)
- \(index_2\) : int
  Index of point contributing to Hausdorff pair in \(v\)

**See also:**

\texttt{scipy.spatial.procrustes}

Another similarity test for two data sets

**Notes**

Uses the early break technique and the random sampling approach described by [R409]. Although worst-case performance is \(O(m \times o)\) (as with the brute force algorithm), this is unlikely in practice as the input data would have to require the algorithm to explore every single point interaction, and after the algorithm shuffles the input points at that. The best case performance is \(O(m)\), which is satisfied by selecting an inner loop distance that is less than \(c_{\text{max}}\) and leads to an early break as often as possible. The authors have formally shown that the average runtime is closer to \(O(m)\).

New in version 0.19.0.

**References**

[R409]

**Examples**

Find the directed Hausdorff distance between two 2-D arrays of coordinates:

```python
from scipy.spatial.distance import directed_hausdorff
u = np.array([[1.0, 0.0],
              [0.0, 1.0],
              [-1.0, 0.0],
              [0.0, -1.0]])
v = np.array([[2.0, 0.0],
              [0.0, 2.0],
              [-2.0, 0.0],
              [0.0, -4.0]])
```
Find the general (symmetric) Hausdorff distance between two 2-D arrays of coordinates:

```python
>>> max(directed_hausdorff(u, v)[0], directed_hausdorff(v, u)[0])
3.0
```

Find the indices of the points that generate the Hausdorff distance (the Hausdorff pair):

```python
>>> directed_hausdorff(v, u)[1:]
(3, 3)
```

Predicates for checking the validity of distance matrices, both condensed and redundant. Also contained in this module are functions for computing the number of observations in a distance matrix.

**Notes**

Small numerical differences in $D$ and $D.T$ and non-zeroness of the diagonal are ignored if they are within the tolerance specified by `tol`.

```python
scipy.spatial.distance.is_valid_y(y, warning=False, throw=False, name=None)
```

Returns True if the input array is a valid condensed distance matrix.

## 5.25. Distance computations (scipy.spatial.distance)
Condensed distance matrices must be 1-dimensional numpy arrays. Their length must be a binomial coefficient \( \binom{n}{2} \) for some positive integer n.

**Parameters**
- `y` : ndarray
  The condensed distance matrix.

  **warning** : bool, optional
  Invokes a warning if the variable passed is not a valid condensed distance matrix. The warning message explains why the distance matrix is not valid. `name` is used when referencing the offending variable.

  **throw** : bool, optional
  Throws an exception if the variable passed is not a valid condensed distance matrix.

  **name** : bool, optional
  Used when referencing the offending variable in the warning or exception message.

**scipy.spatial.distance.num_obs_dm**

Returns the number of original observations that correspond to a square, redundant distance matrix.

**Parameters**
- `d` : ndarray
  The target distance matrix.

**Returns**
- `num_obs_dm` : int
  The number of observations in the redundant distance matrix.

**scipy.spatial.distance.num_obs_y**

Returns the number of original observations that correspond to a condensed distance matrix.

**Parameters**
- `Y` : ndarray
  Condensed distance matrix.

**Returns**
- `n` : int
  The number of observations in the condensed distance matrix `Y`.

Distance functions between two numeric vectors `u` and `v`. Computing distances over a large collection of vectors is inefficient for these functions. Use `pdist` for this purpose.

- `braycurtis(u, v[, w])` Computes the Bray-Curtis distance between two 1-D arrays.
- `canberra(u, v[, w])` Computes the Canberra distance between two 1-D arrays.
- `chebyshev(u, v)` Computes the Chebyshev distance.
- `cityblock(u, v[, w])` Computes the City Block (Manhattan) distance.
- `correlation(u, v[, w, centered])` Computes the correlation distance between two 1-D arrays.
- `cosine(u, v[, w])` Computes the Cosine distance between 1-D arrays.
- `euclidean(u, v[, w])` Computes the Euclidean distance between two 1-D arrays.
- `mahalanobis(u, v, VI)` Computes the Mahalanobis distance between two 1-D arrays.
- `minkowski(u, v[, p, w])` Computes the Minkowski distance between two 1-D arrays.
- `seuclidean(u, v, V)` Returns the standardized Euclidean distance between two 1-D arrays.
- `sqeuclidean(u, v[, w])` Computes the squared Euclidean distance between two 1-D arrays.
- `wminkowski(u, v, p)` Computes the weighted Minkowski distance between two 1-D arrays.

**scipy.spatial.distance.braycurtis**

Computes the Bray-Curtis distance between two 1-D arrays.
Bray-Curtis distance is defined as
\[
\sum \frac{|u_i - v_i|}{\sum |u_i + v_i|}
\]

The Bray-Curtis distance is in the range [0, 1] if all coordinates are positive, and is undefined if the inputs are of length zero.

**Parameters**
- `u` : (N,) array_like
  Input array.
- `v` : (N,) array_like
  Input array.
- `w` : (N,) array_like, optional
  The weights for each value in u and v. Default is None, which gives each value a weight of 1.0

**Returns**
- `braycurtis` : double
  The Bray-Curtis distance between 1-D arrays u and v.

**scipy.spatial.distance.canberra** *(u, v, w=None)*

Computes the Canberra distance between two 1-D arrays.

The Canberra distance is defined as
\[
d(u, v) = \sum \frac{|u_i - v_i|}{|u_i| + |v_i|}
\]

**Parameters**
- `u` : (N,) array_like
  Input vector.
- `v` : (N,) array_like
  Input vector.
- `w` : (N,) array_like, optional
  The weights for each value in u and v. Default is None, which gives each value a weight of 1.0

**Returns**
- `canberra` : double
  The Canberra distance between vectors u and v.

**Notes**

When `u[i]` and `v[i]` are 0 for given i, then the fraction 0/0 = 0 is used in the calculation.

**scipy.spatial.distance.chebyshev** *(u, v)*

Computes the Chebyshev distance.

Computes the Chebyshev distance between two 1-D arrays u and v, which is defined as
\[
\max_i |u_i - v_i|.
\]

**Parameters**
- `u` : (N,) array_like
  Input vector.
- `v` : (N,) array_like
  Input vector.

**Returns**
- `chebyshev` : double
  The Chebyshev distance between vectors u and v.

**scipy.spatial.distance.cityblock** *(u, v, w=None)*

Computes the City Block (Manhattan) distance.

Computes the Manhattan distance between two 1-D arrays u and v, which is defined as
\[
\sum_i |u_i - v_i|.
\]
**Parameters**

- `u` : (N,) array_like
  Input array.
- `v` : (N,) array_like
  Input array.
- `w` : (N,) array_like, optional
  The weights for each value in `u` and `v`. Default is None, which gives each value a weight of 1.0

**Returns**

- `cityblock` : double
  The City Block (Manhattan) distance between vectors `u` and `v`.

```python
scipy.spatial.distance.correlation(u, v, w=None, centered=True)
```

Computes the correlation distance between two 1-D arrays. The correlation distance between `u` and `v`, is defined as

\[
1 - \frac{(u - \bar{u}) \cdot (v - \bar{v})}{||(u - \bar{u})||_2||(v - \bar{v})||_2}
\]

where \(\bar{u}\) is the mean of the elements of `u` and \(x \cdot y\) is the dot product of `x` and `y`.

**Parameters**

- `u` : (N,) array_like
  Input array.
- `v` : (N,) array_like
  Input array.
- `w` : (N,) array_like, optional
  The weights for each value in `u` and `v`. Default is None, which gives each value a weight of 1.0

**Returns**

- `correlation` : double
  The correlation distance between 1-D array `u` and `v`.

```python
scipy.spatial.distance.cosine(u, v, w=None)
```

Computes the Cosine distance between 1-D arrays. The Cosine distance between `u` and `v`, is defined as

\[
1 - \frac{u \cdot v}{||u||_2 ||v||_2}
\]

where \(u \cdot v\) is the dot product of `u` and `v`.

**Parameters**

- `u` : (N,) array_like
  Input array.
- `v` : (N,) array_like
  Input array.
- `w` : (N,) array_like, optional
  The weights for each value in `u` and `v`. Default is None, which gives each value a weight of 1.0

**Returns**

- `cosine` : double
  The Cosine distance between vectors `u` and `v`.

```python
scipy.spatial.distance.euclidean(u, v, w=None)
```

Computes the Euclidean distance between two 1-D arrays.

The Euclidean distance between 1-D arrays `u` and `v`, is defined as

\[
||(u - v)||_2 \left( \sum (w_i(u_i - v_i)^2) \right)^{1/2}
\]

**Parameters**

- `u` : (N,) array_like
  Input array.
- `v` : (N,) array_like
  Input array.
scipy.spatial.distance.mahalanobis(u, v, VI)
Computes the Mahalanobis distance between two 1-D arrays.

The Mahalanobis distance between 1-D arrays \( u \) and \( v \), is defined as

\[
\sqrt{(u - v)^T V^{-1} (u - v)}
\]

where \( V \) is the covariance matrix. Note that the argument \( VI \) is the inverse of \( V \).

Parameters
- \( u \): (N,) array_like
  - Input array.
- \( v \): (N,) array_like
  - Input array.
- \( VI \): ndarray
  - The inverse of the covariance matrix.

Returns
- \( mahalanobis \): double
  - The Mahalanobis distance between vectors \( u \) and \( v \).

scipy.spatial.distance.minkowski(u, v, p=2, w=None)
Computes the Minkowski distance between two 1-D arrays.

The Minkowski distance between 1-D arrays \( u \) and \( v \), is defined as

\[
||u - v||_p = \left( \sum |u_i - v_i|^p \right)^{1/p}.
\]

\[
\left( \sum w_i \left( |u_i - v_i|^p \right) \right)^{1/p}.
\]

Parameters
- \( u \): (N,) array_like
  - Input array.
- \( v \): (N,) array_like
  - Input array.
- \( p \): int
  - The order of the norm of the difference \( ||u - v||_p \).
- \( w \): (N,) array_like, optional
  - The weights for each value in \( u \) and \( v \). Default is None, which gives each value a weight of 1.0

Returns
- \( minkowski \): double
  - The Minkowski distance between vectors \( u \) and \( v \).

scipy.spatial.distance.seuclidean(u, v, V)
Returns the standardized Euclidean distance between two 1-D arrays.

The standardized Euclidean distance between \( u \) and \( v \).

Parameters
- \( u \): (N,) array_like
  - Input array.
- \( v \): (N,) array_like
  - Input array.
- \( V \): (N,) array_like
  - \( V \) is an 1-D array of component variances. It is usually computed among a larger collection vectors.

Returns
- \( seuclidean \): double
  - The standardized Euclidean distance between vectors \( u \) and \( v \).
scipy.spatial.distance.sqeuclidean(u, v, w=None)

Computes the squared Euclidean distance between two 1-D arrays.

The squared Euclidean distance between \( u \) and \( v \) is defined as

\[
\|u - v\|_2^2 = \left( \sum (w_i|u_i - v_i|^2) \right)
\]

**Parameters**

- **u** : (N,) array_like
  - Input array.
- **v** : (N,) array_like
  - Input array.
- **w** : (N,) array_like, optional
  - The weights for each value in \( u \) and \( v \). Default is None, which gives each value a weight of 1.0

**Returns**

- **sqeuclidean** : double
  - The squared Euclidean distance between vectors \( u \) and \( v \).

scipy.spatial.distance.wminkowski(u, v, p, w)

Computes the weighted Minkowski distance between two 1-D arrays. The weighted Minkowski distance between \( u \) and \( v \), defined as

\[
\left( \sum (|w_i(u_i - v_i)|^p) \right)^{1/p}
\]

**Parameters**

- **u** : (N,) array_like
  - Input array.
- **v** : (N,) array_like
  - Input array.
- **p** : int
  - The order of the norm of the difference \( \|u - v\|_p \).
- **w** : (N,) array_like
  - The weight vector.

**Returns**

- **wminkowski** : double
  - The weighted Minkowski distance between vectors \( u \) and \( v \).

**Notes**

- **wminkowski** is DEPRECATED. It implements a definition where weights are powered. It is recommended to use the weighted version of **minkowski** instead. This function will be removed in a future version of scipy.

Distance functions between two boolean vectors (representing sets) \( u \) and \( v \). As in the case of numerical vectors, **pdist** is more efficient for computing the distances between all pairs.

- **dice** \( u, v[, w] \)
  - Computes the Dice dissimilarity between two boolean 1-D arrays.
- **hamming** \( u, v[, w] \)
  - Computes the Hamming distance between two 1-D arrays.
- **jaccard** \( u, v[, w] \)
  - Computes the Jaccard-Needham dissimilarity between two boolean 1-D arrays.
- **kulsinski** \( u, v[, w] \)
  - Computes the Kulsinski dissimilarity between two boolean 1-D arrays.
- **rogerstanimoto** \( u, v[, w] \)
  - Computes the Rogers-Tanimoto dissimilarity between two boolean 1-D arrays.
- **russellrao** \( u, v[, w] \)
  - Computes the Russell-Rao dissimilarity between two boolean 1-D arrays.
- **sokalmichener** \( u, v[, w] \)
  - Computes the Sokal-Michener dissimilarity between two boolean 1-D arrays.
sokalsneath(u, v[, w])
Computes the Sokal-Sneath dissimilarity between two boolean 1-D arrays.

yule(u, v[, w])
Computes the Yule dissimilarity between two boolean 1-D arrays.

scipy.spatial.distance.dice(u, v, w=None)
Computes the Dice dissimilarity between two boolean 1-D arrays.

The Dice dissimilarity between $u$ and $v$, is

$$\frac{c_{TF} + c_{FT}}{2c_{TT} + c_{FT} + c_{TF}}$$

where $c_{ij}$ is the number of occurrences of $u[k] = i$ and $v[k] = j$ for $k < n$.

**Parameters**
- $u$: (N,) ndarray, bool
  Input 1-D array.
- $v$: (N,) ndarray, bool
  Input 1-D array.
- $w$: (N,) array_like, optional
  The weights for each value in $u$ and $v$. Default is None, which gives each value a weight of 1.0

**Returns**
- dice: double
  The Dice dissimilarity between 1-D arrays $u$ and $v$.

scipy.spatial.distance.hamming(u, v, w=None)
Computes the Hamming distance between two 1-D arrays.

The Hamming distance between 1-D arrays $u$ and $v$, is simply the proportion of disagreeing components in $u$ and $v$. If $u$ and $v$ are boolean vectors, the Hamming distance is

$$\frac{c_{01} + c_{10}}{n}$$

where $c_{ij}$ is the number of occurrences of $u[k] = i$ and $v[k] = j$ for $k < n$.

**Parameters**
- $u$: (N,) array_like, bool
  Input array.
- $v$: (N,) array_like, bool
  Input array.
- $w$: (N,) array_like, optional
  The weights for each value in $u$ and $v$. Default is None, which gives each value a weight of 1.0

**Returns**
- hamming: double
  The Hamming distance between vectors $u$ and $v$.

scipy.spatial.distance.jaccard(u, v, w=None)
Computes the Jaccard-Needham dissimilarity between two boolean 1-D arrays.

The Jaccard-Needham dissimilarity between 1-D boolean arrays $u$ and $v$, is defined as

$$\frac{c_{TF} + c_{FT}}{c_{TT} + c_{FT} + c_{TF}}$$

where $c_{ij}$ is the number of occurrences of $u[k] = i$ and $v[k] = j$ for $k < n$.

**Parameters**
- $u$: (N,) array_like, bool
  Input array.
- $v$: (N,) array_like, bool
  Input array.
w : (N,) array_like, optional

The weights for each value in u and v. Default is None, which gives each value a weight of 1.0

Returns jaccard : double

The Jaccard distance between vectors u and v.

scipy.spatial.distance.kulsinski(u, v, w=None)

Computes the Kulsinski dissimilarity between two boolean 1-D arrays.

The Kulsinski dissimilarity between two boolean 1-D arrays u and v, is defined as

\[
\frac{c_{TF} + c_{FT} - c_{TT} + n}{c_{FT} + c_{TF} + n}
\]

where \(c_{ij}\) is the number of occurrences of \(u[k] = i\) and \(v[k] = j\) for \(k < n\).

Parameters u : (N,) array_like, bool

Input array.

v : (N,) array_like, bool

Input array.

w : (N,) array_like, optional

The weights for each value in u and v. Default is None, which gives each value a weight of 1.0

Returns kulsinski : double

The Kulsinski distance between vectors u and v.

scipy.spatial.distance.rogerstanimoto(u, v, w=None)

Computes the Rogers-Tanimoto dissimilarity between two boolean 1-D arrays.

The Rogers-Tanimoto dissimilarity between two boolean 1-D arrays u and v, is defined as

\[
\frac{R}{c_{TT} + c_{FF} + R}
\]

where \(c_{ij}\) is the number of occurrences of \(u[k] = i\) and \(v[k] = j\) for \(k < n\) and \(R = 2(c_{TF} + c_{FT})\).

Parameters u : (N,) array_like, bool

Input array.

v : (N,) array_like, bool

Input array.

w : (N,) array_like, optional

The weights for each value in u and v. Default is None, which gives each value a weight of 1.0

Returns rogerstanimoto : double

The Rogers-Tanimoto dissimilarity between vectors u and v.

scipy.spatial.distance.russellrao(u, v, w=None)

Computes the Russell-Rao dissimilarity between two boolean 1-D arrays.

The Russell-Rao dissimilarity between two boolean 1-D arrays, u and v, is defined as

\[
\frac{n - c_{TT}}{n}
\]

where \(c_{ij}\) is the number of occurrences of \(u[k] = i\) and \(v[k] = j\) for \(k < n\).

Parameters u : (N,) array_like, bool

Input array.

v : (N,) array_like, bool

Input array.

w : (N,) array_like, optional

The weights for each value in u and v. Default is None, which gives each value a weight of 1.0

1554 Chapter 5. API Reference
scipy.spatial.distance\texttt{sokalmichener}(u, v, w=\texttt{None})

Computes the Sokal-Michener dissimilarity between two boolean 1-D arrays.

The Sokal-Michener dissimilarity between boolean 1-D arrays \( u \) and \( v \), is defined as

\[
\frac{R}{S + R}
\]

where \( c_{ij} \) is the number of occurrences of \( u[k] = i \) and \( v[k] = j \) for \( k < n \), \( R = 2 \times (c_{TF} + c_{FT}) \) and \( S = c_{FF} + c_{TT} \).

Parameters  
\( u \) : (N,) array_like, bool
  Input array.
\( v \) : (N,) array_like, bool
  Input array.
\( w \) : (N,) array_like, optional
  The weights for each value in \( u \) and \( v \). Default is None, which gives each value a weight of 1.0

Returns  
\texttt{sokalmichener} : double
  The Sokal-Michener dissimilarity between vectors \( u \) and \( v \).

scipy.spatial.distance\texttt{sokalsneath}(u, v, w=\texttt{None})

Computes the Sokal-Sneath dissimilarity between two boolean 1-D arrays.

The Sokal-Sneath dissimilarity between \( u \) and \( v \),

\[
\frac{R}{c_{TT} + R}
\]

where \( c_{ij} \) is the number of occurrences of \( u[k] = i \) and \( v[k] = j \) for \( k < n \) and \( R = 2(c_{TF} + c_{FT}) \).

Parameters  
\( u \) : (N,) array_like, bool
  Input array.
\( v \) : (N,) array_like, bool
  Input array.
\( w \) : (N,) array_like, optional
  The weights for each value in \( u \) and \( v \). Default is None, which gives each value a weight of 1.0

Returns  
\texttt{sokalsneath} : double
  The Sokal-Sneath dissimilarity between vectors \( u \) and \( v \).

scipy.spatial.distance\texttt{yule}(u, v, w=\texttt{None})

Computes the Yule dissimilarity between two boolean 1-D arrays.

The Yule dissimilarity is defined as

\[
\frac{R}{c_{TT} \times c_{FF} + \frac{R}{2}}
\]

where \( c_{ij} \) is the number of occurrences of \( u[k] = i \) and \( v[k] = j \) for \( k < n \) and \( R = 2.0 \times c_{TF} \times c_{FT} \).

Parameters  
\( u \) : (N,) array_like, bool
  Input array.
\( v \) : (N,) array_like, bool
  Input array.
\( w \) : (N,) array_like, optional
  The weights for each value in \( u \) and \( v \). Default is None, which gives each value a weight of 1.0

Returns  
\texttt{yule} : double
  The Yule dissimilarity between vectors \( u \) and \( v \).
The Yule dissimilarity between vectors \( u \) and \( v \).

`hamming` also operates over discrete numerical vectors.

## 5.26 Special functions (scipy.special)

Nearly all of the functions below are universal functions and follow broadcasting and automatic array-looping rules. Exceptions are noted.

See also:

`scipy.special.cython_special` — Typed Cython versions of special functions

### 5.26.1 Error handling

Errors are handled by returning NaNs or other appropriate values. Some of the special function routines can emit warnings or raise exceptions when an error occurs. By default this is disabled; to query and control the current error handling state the following functions are provided.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>geterr</code></td>
<td>Get the current way of handling special-function errors.</td>
</tr>
<tr>
<td><code>seterr</code></td>
<td>Set how special-function errors are handled.</td>
</tr>
<tr>
<td><code>errstate</code></td>
<td>Context manager for special-function error handling.</td>
</tr>
<tr>
<td><code>SpecialFunctionWarning</code></td>
<td>Warning that can be emitted by special functions.</td>
</tr>
<tr>
<td><code>SpecialFunctionError</code></td>
<td>Exception that can be raised by special functions.</td>
</tr>
</tbody>
</table>

### scipy.special.geterr()

Get the current way of handling special-function errors.

**Returns**

err : dict

A dictionary with keys “singular”, “underflow”, “overflow”, “slow”, “loss”, “no_result”, “domain”, “arg”, and “other”, whose values are from the strings “ignore”, “warn”, and “raise”. The keys represent possible special-function errors, and the values define how these errors are handled.

See also:

`seterr` set how special-function errors are handled
`errstate` context manager for special-function error handling
`numpy.geterr` similar numpy function for floating-point errors

**Notes**

For complete documentation of the types of special-function errors and treatment options, see `seterr`.

**Examples**

By default all errors are ignored.

```python
>>> import scipy.special as sc
>>> for key, value in sorted(sc.geterr().items()):
...     print(f"{key}: /{value}"
...     arg: ignore
...     domain: ignore
```
scipy.special.seterr()

Set how special-function errors are handled.

Parameters

**all**: {'ignore', 'warn', 'raise'}, optional
Set treatment for all type of special-function errors at once. The options are:

- 'ignore': Take no action when the error occurs
- 'warn': Print a `SpecialFunctionWarning` when the error occurs (via the Python `warnings` module)
- 'raise': Raise a `SpecialFunctionError` when the error occurs.

The default is to not change the current behavior. If behaviors for additional categories of special-function errors are specified, then `all` is applied first, followed by the additional categories.

**singular**: {'ignore', 'warn', 'raise'}, optional
Treatment for singularities.

**underflow**: {'ignore', 'warn', 'raise'}, optional
Treatment for underflow.

**overflow**: {'ignore', 'warn', 'raise'}, optional
Treatment for overflow.

**slow**: {'ignore', 'warn', 'raise'}, optional
Treatment for slow convergence.

**loss**: {'ignore', 'warn', 'raise'}, optional
Treatment for loss of accuracy.

**no_result**: {'ignore', 'warn', 'raise'}, optional
Treatment for failing to find a result.

**domain**: {'ignore', 'warn', 'raise'}, optional
Treatment for an invalid argument to a function.

**arg**: {'ignore', 'warn', 'raise'}, optional
Treatment for an invalid parameter to a function.

**other**: {'ignore', 'warn', 'raise'}, optional
Treatment for an unknown error.

Returns

`olderr` : dict
Dictionary containing the old settings.

See also:

* `geterr` get the current way of handling special-function errors
* `errstate` context manager for special-function error handling
* `numpy.seterr` similar numpy function for floating-point errors

Examples

```python
>>> import scipy.special as sc
>>> from pytest import raises
>>> sc.gammaln(0)
inf
>>> olderr = sc.seterr(singular='raise')
```
>>> with raises(sc.SpecialFunctionError):
...    sc.gammafn(0)
...    sc.spence(-1)

We can also raise for every category except one.

```python
olderr = sc.seterr(all='raise', singular='ignore')
sc.gammafn(0)  # inf
>>> with raises(sc.SpecialFunctionError):
...    sc.gammafn(0)
...    sc.spence(-1)

_ = sc.seterr(**olderr)
```

class `scipy.special.errstate`
Context manager for special-function error handling.

Using an instance of `errstate` as a context manager allows statements in that context to execute with a known error handling behavior. Upon entering the context the error handling is set with `seterr`, and upon exiting it is restored to what it was before.

**Parameters**

`kwargs` : {all, singular, underflow, overflow, slow, loss, no_result, domain, arg, other}
Keyword arguments. The valid keywords are possible special-function errors. Each keyword should have a string value that defines the treatment for the particular type of error. Values must be ‘ignore’, ‘warn’, or ‘other’. See :func:`seterr` for details.

**See also:**

- :func:`geterr` to get the current way of handling special-function errors
- :func:`seterr` to set how special-function errors are handled
- :func:`numpy.errstate` for similar numpy function for floating-point errors

**Examples**

```python
>>> import scipy.special as sc
>>> from pytest import raises

>>> sc.gammafn(0)  # inf
>>> with sc.errstate(singular='raise'):
...    with raises(sc.SpecialFunctionError):
...        sc.gammafn(0)
...        sc.spence(-1)

_ = sc.gammafn(0)  # inf
```

We can also raise on every category except one.

```python
>>> with sc.errstate(all='raise', singular='ignore'):
...    sc.gammafn(0)
...    with raises(sc.SpecialFunctionError):
...        sc.spence(-1)
...        inf
```
exception scipy.special.SpecialFunctionWarning
Warning that can be emitted by special functions.

exception scipy.special.SpecialFunctionError
Exception that can be raised by special functions.

## 5.26.2 Available functions

### Airy functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>airy(z)</td>
<td>Airy functions and their derivatives.</td>
</tr>
<tr>
<td>airye(z)</td>
<td>Exponentially scaled Airy functions and their derivatives.</td>
</tr>
<tr>
<td>ai_zeros(nt)</td>
<td>Compute nt zeros and values of the Airy function Ai and its derivative.</td>
</tr>
<tr>
<td>bi_zeros(nt)</td>
<td>Compute nt zeros and values of the Airy function Bi and its derivative.</td>
</tr>
<tr>
<td>itairy(x)</td>
<td>Integrals of Airy functions</td>
</tr>
</tbody>
</table>

**scipy.special.airy(z) = <ufunc ‘airy’>**

Airy functions and their derivatives.

**Parameters**

- `z`: array_like
  Real or complex argument.

**Returns**

- `Ai, Aip, Bi, Bip`: ndarrays
  Airy functions Ai and Bi, and their derivatives Aip and Bip.

**See also:**

- airy: exponentially scaled Airy functions.

**Notes**

The Airy functions Ai and Bi are two independent solutions of

\[ y''(x) = xy(x). \]

For real \( z \) in \([-10, 10]\), the computation is carried out by calling the Cephes [R413] airy routine, which uses power series summation for small \( z \) and rational minimax approximations for large \( z \).

Outside this range, the AMOS [R414] zairy and zbiry routines are employed. They are computed using power series for \(|z| < 1\) and the following relations to modified Bessel functions for larger \( z \) (where \( t \equiv 2z^{3/2}/3 \)):

\[
Ai(z) = \frac{1}{\pi \sqrt{3}} K_{1/3}(t)
\]

\[
Ai'(z) = -\frac{z}{\pi \sqrt{3}} K_{2/3}(t)
\]

\[
Bi(z) = \sqrt{\frac{z}{3}} (I_{-1/3}(t) + I_{1/3}(t))
\]

\[
Bi'(z) = \frac{z}{\sqrt{3}} (I_{-2/3}(t) + I_{2/3}(t))
\]

**References**

[R413], [R414]
Examples

Compute the Airy functions on the interval [-15, 5].

```python
>>> from scipy import special
>>> x = np.linspace(-15, 5, 201)
>>> ai, aip, bi, bip = special.airy(x)
```

Plot Ai(x) and Bi(x).

```python
>>> import matplotlib.pyplot as plt

>>> plt.plot(x, ai, 'r', label='Ai(x)')
>>> plt.plot(x, bi, 'b--', label='Bi(x)')
>>> plt.ylim(-0.5, 1.0)
>>> plt.grid()
>>> plt.legend(loc='upper left')
>>> plt.show()
```

```
scipy.special.airy(z) = <ufunc 'airy'>
```

Exponentially scaled Airy functions and their derivatives.

Scaling:

```
EAi = Ai * exp(2.0/3.0*z*sqrt(z))
EAlp = Aip * exp(2.0/3.0*z*sqrt(z))
EBi = Bi * exp(-abs(2.0/3.0*(z*sqrt(z)).real))
EBip = Bip * exp(-abs(2.0/3.0*(z*sqrt(z)).real))
```

- **Parameters**
  - `z`: array_like

- **Returns**
  - `eAi, eAlp, eBi, eBip`: array_like

  Airy functions Ai and Bi, and their derivatives Aip and Bip

See also:

airy
Notes
Wrapper for the AMOS [R415] routines zairy and zbiry.

References
[R415]
scipy.special.ai_zeros(nt)
Compute nt zeros and values of the Airy function Ai and its derivative.
Computes the first nt zeros, a, of the Airy function Ai(x); first nt zeros, ap, of the derivative of the Airy function Ai’(x); the corresponding values Ai(a’); and the corresponding values Ai’(a).

Parameters
- nt : int
  Number of zeros to compute

Returns
- a : ndarray
  First nt zeros of Ai(x)
- ap : ndarray
  First nt zeros of Ai’(x)
- ai : ndarray
  Values of Ai(x) evaluated at first nt zeros of Ai’(x)
- aip : ndarray
  Values of Ai’(x) evaluated at first nt zeros of Ai(x)

References
[R412]
scipy.special.bi_zeros(nt)
Compute nt zeros and values of the Airy function Bi and its derivative.
Computes the first nt zeros, b, of the Airy function Bi(x); first nt zeros, b’, of the derivative of the Airy function Bi’(x); the corresponding values Bi(b’); and the corresponding values Bi’(b).

Parameters
- nt : int
  Number of zeros to compute

Returns
- b : ndarray
  First nt zeros of Bi(x)
- bp : ndarray
  First nt zeros of Bi’(x)
- bi : ndarray
  Values of Bi(x) evaluated at first nt zeros of Bi’(x)
- bip : ndarray
  Values of Bi’(x) evaluated at first nt zeros of Bi(x)

References
[R428]
scipy.special.itairy(x) = <ufunc ‘itairy’>
Integrals of Airy functions
Calculates the integrals of Airy functions from 0 to x.

Parameters
- x: array_like
  Upper limit of integration (float).

Returns
- Apt
  Integral of Ai(t) from 0 to x.
- Bpt
  Integral of Bi(t) from 0 to x.
- Ant

5.26. Special functions (scipy.special) 1561
Integral of Ai(-t) from 0 to x.

\[ B_{nt} \]

Integral of Bi(-t) from 0 to x.

Notes

Wrapper for a Fortran routine created by Shanjie Zhang and Jianming Jin [R496].

</tbody>
</table>

\[ \text{scipy.special.ellipj}(u, m) = \langle \text{ufunc `ellipj'} > \]

Calculates the Jacobian elliptic functions of parameter \( m \) between 0 and 1, and real argument \( u \).

**Parameters**

- \( m \) : array_like
  Parameter.
- \( u \) : array_like
  Argument.

**Returns**

- \( \text{sn}, \text{cn}, \text{dn}, \text{ph} \) : ndarrays
  The returned functions:
  \[ \text{sn}(u|m), \text{cn}(u|m), \text{dn}(u|m) \]
  The value \( ph \) is such that if \( u = \text{ellipk}(ph, m) \), then \( \text{sn}(u|m) = \sin(ph) \) and \( \text{cn}(u|m) = \cos(ph) \).

See also:

- `ellipk` Complete elliptic integral of the first kind.

Notes

Wrapper for the Cephes [R451] routine `ellpj`.

These functions are periodic, with quarter-period on the real axis equal to the complete elliptic integral `ellipk(m).`

Relation to incomplete elliptic integral: If \( u = \text{ellipk}(\phi, m) \), then \( \text{sn}(u|m) = \sin(\phi) \) and \( \text{cn}(u|m) = \cos(\phi) \). The \( \phi \) is called the amplitude of \( u \).

Computation is by means of the arithmetic-geometric mean algorithm, except when \( m \) is within 1e-9 of 0 or 1. In the latter case with \( m \) close to 1, the approximation applies only for \( \phi < \pi/2 \).

References

[R451]
scipy.special.ellipk(m)
Complete elliptic integral of the first kind.

This function is defined as

\[ K(m) = \int_0^{\pi/2} \frac{1}{\sqrt{1 - m \sin^2(t)}} dt \]

**Parameters**  
\( m \) : array_like  

**Returns**  
\( K \) : array_like  
The parameter of the elliptic integral.  
Value of the elliptic integral.

See also:
- ellipkm1 Complete elliptic integral of the first kind around \( m = 1 \)
- ellipkinc Incomplete elliptic integral of the first kind
- ellipe Complete elliptic integral of the second kind
- ellipeinc Incomplete elliptic integral of the second kind

Notes
For more precision around point \( m = 1 \), use ellipkm1, which this function calls.

The parameterization in terms of \( m \) follows that of section 17.2 in [R452]. Other parameterizations in terms of the complementary parameter \( 1 - m \), modular angle \( \sin^2(\alpha) = m \), or modulus \( k^2 = m \) are also used, so be careful that you choose the correct parameter.

References
[R452]

scipy.special.ellipkm1(p) = <ufunc 'ellipkm1'>
Complete elliptic integral of the first kind around \( m = 1 \)

This function is defined as

\[ K(p) = \int_0^{\pi/2} \frac{1}{\sqrt{1 - m \sin^2(t)}} dt \]

where \( m = 1 - p \).

**Parameters**  
\( p \) : array_like  

**Returns**  
\( K \) : ndarray  
Defines the parameter of the elliptic integral as \( m = 1 - p \).  
Value of the elliptic integral.

See also:
- ellipk Complete elliptic integral of the first kind
- ellipkinc Incomplete elliptic integral of the first kind
- ellipe Complete elliptic integral of the second kind
- ellipeinc Incomplete elliptic integral of the second kind

Notes
Wrapper for the Cephes [R455] routine ellpk.

For \( p \leq 1 \), computation uses the approximation,

\[ K(p) \approx P(p) - \log(p)Q(p), \]
where \( P \) and \( Q \) are tenth-order polynomials. The argument \( p \) is used internally rather than \( m \) so that the logarithmic singularity at \( m = 1 \) will be shifted to the origin; this preserves maximum accuracy. For \( p > 1 \), the identity

\[
K(p) = K(1/p)/\sqrt(p)
\]

is used.

References

[R455]

scipy.special.ellipkinc \((phi, m) = \text{<ufunc 'ellipkinc'>}
Incomplete elliptic integral of the first kind

This function is defined as

\[
K(\phi, m) = \int_0^\phi \left[1 - m \sin(t)^2\right]^{-1/2} dt
\]

This function is also called \( F(\phi, m) \).

Parameters

- **phi**: array_like
  amplitude of the elliptic integral
- **m**: array_like

Returns

- **K**: ndarray
  Value of the elliptic integral

See also:

- ellipkm1 Complete elliptic integral of the first kind, near \( m = 1 \)
- ellipk Complete elliptic integral of the first kind
- ellipe Complete elliptic integral of the second kind
- ellipeinc Incomplete elliptic integral of the second kind

Notes

Wrapper for the Cephes [R453] routine ellik. The computation is carried out using the arithmetic-geometric mean algorithm.

The parameterization in terms of \( m \) follows that of section 17.2 in [R454]. Other parameterizations in terms of the complementary parameter \( 1 - m \), modular angle \( \sin^2(\alpha) = m \), or modulus \( k^2 = m \) are also used, so be careful that you choose the correct parameter.

References

[R453], [R454]

scipy.special.ellipe \((m) = \text{<ufunc 'ellipe'>}
Complete elliptic integral of the second kind

This function is defined as

\[
E(m) = \int_0^{\pi/2} [1 - m \sin(t)^2]^{1/2} dt
\]

Parameters

- **m**: array_like

Returns

- **E**: ndarray
  Defines the parameter of the elliptic integral.

Value of the elliptic integral.

See also:
ellipkm1  Complete elliptic integral of the first kind, near \( m = 1 \)
ellipk  Complete elliptic integral of the first kind
ellipkinc  Incomplete elliptic integral of the first kind
ellipeinc  Incomplete elliptic integral of the second kind

Notes
Wrapper for the Cephes [R447] routine ellpe.
For \( m > 0 \) the computation uses the approximation,

\[
E(m) \approx P(1-m) - (1-m) \log(1-m)Q(1-m),
\]

where \( P \) and \( Q \) are tenth-order polynomials. For \( m < 0 \), the relation

\[
E(m) = E(m/(m-1)) \sqrt{1-m}
\]

is used.
The parameterization in terms of \( m \) follows that of section 17.2 in [R448]. Other parameterizations in terms of the complementary parameter \( 1-m \), modular angle \( \sin^2(\alpha) = m \), or modulus \( k^2 = m \) are also used, so be careful that you choose the correct parameter.

References
[R447], [R448]

scipy.special.ellipeinc(phi, m) = <ufunc ‘ellipeinc’>
Incomplete elliptic integral of the second kind
This function is defined as

\[
E(\phi, m) = \int_0^\phi \left[ 1 - m \sin(t)^2 \right]^{1/2} dt
\]

Parameters
phi : array_like
amplitude of the elliptic integral.
m : array_like

Returns
E : ndarray
Value of the elliptic integral.

See also:
ellipkm1  Complete elliptic integral of the first kind, near \( m = 1 \)
ellipk  Complete elliptic integral of the first kind
ellipkinc  Incomplete elliptic integral of the first kind
ellipe  Complete elliptic integral of the second kind

Notes
Wrapper for the Cephes [R449] routine ellie.
Computation uses arithmetic-geometric means algorithm.
The parameterization in terms of \( m \) follows that of section 17.2 in [R450]. Other parameterizations in terms of the complementary parameter \( 1-m \), modular angle \( \sin^2(\alpha) = m \), or modulus \( k^2 = m \) are also used, so be careful that you choose the correct parameter.

References
[R449], [R450]
Bessel Functions

\( jv(v, z) \) Bessel function of the first kind of real order and complex argument.

\( jn(n, x) \) Bessel function of the second kind of integer order and real argument.

\( jv(n, x) \) Bessel function of the second kind of real order and complex argument.

\( jve(v, z) \) Exponentially scaled Bessel function of order \( v \).

\( yn(v, z) \) Bessel function of the second kind of integer order and real argument.

\( yv(v, z) \) Bessel function of the second kind of real order and complex argument.

\( yve(v, z) \) Exponentially scaled Bessel function of the second kind of real order.

\( kn(n, x) \) Modified Bessel function of the second kind of integer order \( n \).

\( kv(v, z) \) Modified Bessel function of the second kind of real order \( v \).

\( kve(v, z) \) Exponentially scaled modified Bessel function of the second kind.

\( iv(v, z) \) Modified Bessel function of the first kind of real order.

\( ive(v, z) \) Exponentially scaled modified Bessel function of the first kind.

\( hankel1(v, z) \) Hankel function of the first kind.

\( hankel2e(v, z) \) Exponentially scaled Hankel function of the first kind.

\( hankel2(v, z) \) Hankel function of the second kind.

\( hankel2e(v, z) \) Exponentially scaled Hankel function of the second kind.

\texttt{scipy.special.jv(v, z) = <ufunc ‘jv’>}

Bessel function of the first kind of real order and complex argument.

\textbf{Parameters}

\begin{itemize}
  \item \( v \) : array_like
    Order (float).
  \item \( z \) : array_like
    Argument (float or complex).
\end{itemize}

\textbf{Returns}

\( J \) : ndarray
   Value of the Bessel function, \( J_v(z) \).

\textbf{See also:}

\texttt{jve} \( J_v \) with leading exponential behavior stripped off.

\texttt{spherical_jn} spherical Bessel functions.

\textbf{Notes}

For positive \( v \) values, the computation is carried out using the AMOS \texttt{zbessj} routine, which exploits the connection to the modified Bessel function \( I_v \),

\[
J_v(z) = \exp(v\pi i/2)I_v(-iz) \quad (\Im z > 0)
\]

\[
J_v(z) = \exp(-v\pi i/2)I_v(iz) \quad (\Im z < 0)
\]

For negative \( v \) values the formula,

\[
J_{-v}(z) = J_v(z) \cos(\pi v) - Y_v(z) \sin(\pi v)
\]

is used, where \( Y_v(z) \) is the Bessel function of the second kind, computed using the AMOS routine \texttt{zbessy}. Note that the second term is exactly zero for integer \( v \); to improve accuracy the second term is explicitly omitted for \( v \) values such that \( v = \text{floor}(v) \).
Not to be confused with the spherical Bessel functions (see `spherical_jn`).

**References**

[R511]

```python
scipy.special.jn(v, z) = <ufunc 'jv'>
```

Bessel function of the first kind of real order and complex argument.

**Parameters**

- `v`: array_like
  Order (float).
- `z`: array_like
  Argument (float or complex).

**Returns**

- `J`: ndarray
  Value of the Bessel function, $J_v(z)$.

**See also:**

- `jve`: $J_v$ with leading exponential behavior stripped off.
- `spherical_jn`: spherical Bessel functions.

**Notes**

For positive $v$ values, the computation is carried out using the AMOS [R506] `zbesj` routine, which exploits the connection to the modified Bessel function $I_v$,

$$
J_v(z) = \exp(v\pi i/2)I_v(-iz) \quad (\Im z > 0)
$$

$$
J_v(z) = \exp(-v\pi i/2)I_v(iz) \quad (\Im z < 0)
$$

For negative $v$ values the formula,

$$
J_{-v}(z) = J_v(z) \cos(\pi v) - Y_v(z) \sin(\pi v)
$$

is used, where $Y_v(z)$ is the Bessel function of the second kind, computed using the AMOS routine `zbesy`. Note that the second term is exactly zero for integer $v$; to improve accuracy the second term is explicitly omitted for $v$ values such that $v = \text{floor}(v)$.

Not to be confused with the spherical Bessel functions (see `spherical_jn`).

**References**

[R506]

```python
scipy.special.jve(v, z) = <ufunc 'jve'>
```

Exponentially scaled Bessel function of order $v$.

Defined as:

$$jve(v, z) = jv(v, z) \times \exp(-\text{abs}(z.\text{imag}))$$

**Parameters**

- `v`: array_like
  Order (float).
- `z`: array_like
  Argument (float or complex).

**Returns**

- `J`: ndarray
  Value of the exponentially scaled Bessel function.
Notes

For positive $v$ values, the computation is carried out using the AMOS [R512] zbesj routine, which exploits the connection to the modified Bessel function $I_v$.

\[
J_v(z) = \exp(v\pi i/2)I_v(-iz) \quad (3z > 0)
\]
\[
J_v(z) = \exp(-v\pi i/2)I_v(iz) \quad (3z < 0)
\]

For negative $v$ values the formula,

\[
J_{-v}(z) = J_v(z) \cos(\pi v) - Y_v(z) \sin(\pi v)
\]

is used, where $Y_v(z)$ is the Bessel function of the second kind, computed using the AMOS routine zbesy. Note that the second term is exactly zero for integer $v$; to improve accuracy the second term is explicitly omitted for $v$ values such that $v = \text{floor}(v)$.

References

[R512]

scipy.special.yn(n, x) = <ufunc ‘yn’>
Bessel function of the second kind of integer order and real argument.

Parameters

- $n$: array_like
  Order (integer).
- $z$: array_like
  Argument (float).

Returns

- $Y$: ndarray
  Value of the Bessel function, $Y_n(x)$.

See also:

yv
For real order and real or complex argument.

Notes

Wrapper for the Cephes [R594] routine yn.

The function is evaluated by forward recurrence on $n$, starting with values computed by the Cephes routines y0 and y1. If $n = 0$ or 1, the routine for y0 or y1 is called directly.

References

[R594]

scipy.special.yv(v, z) = <ufunc ‘yv’>
Bessel function of the second kind of real order and complex argument.

Parameters

- $v$: array_like
  Order (float).
- $z$: array_like
  Argument (float or complex).

Returns

- $Y$: ndarray
  Value of the Bessel function of the second kind, $Y_v(x)$.

See also:

yve
$Y_v$ with leading exponential behavior stripped off.
Notes

For positive $v$ values, the computation is carried out using the AMOS [R597] zbesy routine, which exploits the connection to the Hankel Bessel functions $H^{(1)}_v$ and $H^{(2)}_v$:

$$Y_v(z) = \frac{1}{2i} (H^{(1)}_v - H^{(2)}_v).$$

For negative $v$ values the formula,

$$Y_{-v}(z) = Y_v(z) \cos(\pi v) + J_v(z) \sin(\pi v)$$

is used, where $J_v(z)$ is the Bessel function of the first kind, computed using the AMOS routine zbesj. Note that the second term is exactly zero for integer $v$; to improve accuracy the second term is explicitly omitted for $v$ values such that $v = \text{floor}(v)$.

References

[R597]

scipy.special.yve(v, z) = <ufunc ‘yve’>

Exponentially scaled Bessel function of the second kind of real order.

Returns the exponentially scaled Bessel function of the second kind of real order $v$ at complex $z$:

\[
yve(v, z) = yv(v, z) \times \exp(-\text{abs}(z.\text{imag}))
\]

Parameters

$v$ : array_like

Order (float).

$z$ : array_like

Argument (float or complex).

Returns

$Y$ : ndarray

Value of the exponentially scaled Bessel function.

Notes

For positive $v$ values, the computation is carried out using the AMOS [R598] zbesy routine, which exploits the connection to the Hankel Bessel functions $H^{(1)}_v$ and $H^{(2)}_v$:

$$Y_v(z) = \frac{1}{2i} (H^{(1)}_v - H^{(2)}_v).$$

For negative $v$ values the formula,

$$Y_{-v}(z) = Y_v(z) \cos(\pi v) + J_v(z) \sin(\pi v)$$

is used, where $J_v(z)$ is the Bessel function of the first kind, computed using the AMOS routine zbesj. Note that the second term is exactly zero for integer $v$; to improve accuracy the second term is explicitly omitted for $v$ values such that $v = \text{floor}(v)$.

References

[R598]

scipy.special.kn(n, x) = <ufunc ‘kn’>

Modified Bessel function of the second kind of integer order $n$

Returns the modified Bessel function of the second kind for integer order $n$ at real $z$.

These are also sometimes called functions of the third kind, Basset functions, or Macdonald functions.

Parameters

$n$ : array_like of int
Order of Bessel functions (floats will truncate with a warning)

\[
z : \text{array_like of float}
\]

\[
\text{out : ndarray}
\]

Returns

Argument at which to evaluate the Bessel functions

The results

See also:

- \text{kv}
  Same function, but accepts real order and complex argument
- \text{kvp}
  Derivative of this function

Notes

Wrapper for AMOS [R523] routine \text{zbesk}. For a discussion of the algorithm used, see [R524] and the references therein.

References

[R523], [R524]

Examples

Plot the function of several orders for real input:

```python
gf

>>> from scipy.special import kn
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(0, 5, 1000)
>>> for N in range(6):
...     plt.plot(x, kn(N, x), label='$K_{\text{0}}(x)$'.format(N))
>>> plt.ylim(0, 10)
>>> plt.legend()
>>> plt.title(r'Modified Bessel function of the second kind $K_n(x)$')
>>> plt.show()
```

Calculate for a single value at multiple orders:

```python

>>> kn([4, 5, 6], 1)
a\text{array}([44.23241585, 360.9605896 , 3653.83831186])
```
scipy.special.kv(v, z) = <ufunc 'kv'>

Modified Bessel function of the second kind of real order \( v \)

Returns the modified Bessel function of the second kind for real order \( v \) at complex \( z \).

These are also sometimes called functions of the third kind, Basset functions, or Macdonald functions. They are defined as those solutions of the modified Bessel equation for which,

\[
K_v(x) \sim \sqrt{\pi/(2x)} \exp(-x)
\]

as \( x \to \infty \) [R527].

**Parameters**

- \( v \) : array_like of float
  
  Order of Bessel functions

- \( z \) : array_like of complex
  
  Argument at which to evaluate the Bessel functions

**Returns**

- \( out \) : ndarray
  
  The results. Note that input must be of complex type to get complex output, e.g.
  
  \( \text{kv}(3, -2+0j) \) instead of \( \text{kv}(3, -2) \).

**See also:**

- `kve`
  
  This function with leading exponential behavior stripped off.

- `kvp`
  
  Derivative of this function

**Notes**

Wrapper for AMOS [R525] routine `zbek`. For a discussion of the algorithm used, see [R526] and the references therein.

**References**

[R525], [R526], [R527]

**Examples**

Plot the function of several orders for real input:

```python
>>> from scipy.special import kv
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(0, 5, 1000)
>>> for N in np.linspace(0, 6, 5):
...     plt.plot(x, kv(N, x), label='$K_{\{\}}(x)$'.format(N))
>>> plt.ylim(0, 10)
>>> plt.legend()
>>> plt.title(r'Modified Bessel function of the second kind $K_\nu(x)$')
>>> plt.show()
```
Calculate for a single value at multiple orders:

```python
>>> kv([4, 4.5, 5], 1+2j)
aarray([ 0.1992+2.3892j, 2.3493+3.6j , 7.2827+3.8104j])
```

scipy.special.kve(v, z) = <ufunc ‘kve’>

Exponentially scaled modified Bessel function of the second kind.

Returns the exponentially scaled, modified Bessel function of the second kind (sometimes called the third kind) for real order v at complex z:

\[
\text{kve}(v, z) = \text{kv}(v, z) \times \exp(z)
\]

Parameters

- v : array_like of float
  Order of Bessel functions
- z : array_like of complex
  Argument at which to evaluate the Bessel functions

Returns

- out : ndarray
  The exponentially scaled modified Bessel function of the second kind.

Notes

Wrapper for AMOS [R528] routine zbesk. For a discussion of the algorithm used, see [R529] and the references therein.

References

[R528], [R529]

scipy.special.iv(v, z) = <ufunc ‘iv’>

Modified Bessel function of the first kind of real order.

Parameters

- v : array_like
  Order. If z is of real type and negative, v must be integer valued.
- z : array_like of float or complex
  Argument.

Returns

- out : ndarray
  Values of the modified Bessel function.
See also:

kve

This function with leading exponential behavior stripped off.

Notes

For real $z$ and $v \in [-50, 50]$, the evaluation is carried out using Temme’s method [R499]. For larger orders, uniform asymptotic expansions are applied.

For complex $z$ and positive $v$, the AMOS [R500] zbesi routine is called. It uses a power series for small $z$, the asymptotic expansion for large $\text{abs}(z)$, the Miller algorithm normalized by the Wronskian and a Neumann series for intermediate magnitudes, and the uniform asymptotic expansions for $I_v(z)$ and $J_v(z)$ for large orders. Backward recurrence is used to generate sequences or reduce orders when necessary.

The calculations above are done in the right half plane and continued into the left half plane by the formula,

$$I_v(z \exp(\pm i\pi)) = \exp(\pm \pi v) I_v(z)$$

(valid when the real part of $z$ is positive). For negative $v$, the formula

$$I_{-v}(z) = I_v(z) + 2\pi \sin(\pi v) K_v(z)$$

is used, where $K_v(z)$ is the modified Bessel function of the second kind, evaluated using the AMOS routine zbesk.

References

[R499], [R500]

\texttt{scipy.special.ive}(v, z) = \texttt{ufunc ‘ive’}

Exponentially scaled modified Bessel function of the first kind

Defined as:

\[
\text{ive}(v, z) = \text{iv}(v, z) \times \exp(-\text{abs}(z.\text{real}))
\]

Parameters

- $v$: array_like of float
  Order.
- $z$: array_like of float or complex
  Argument.

Returns

- $\text{out}$: ndarray
  Values of the exponentially scaled modified Bessel function.

Notes

For positive $v$, the AMOS [R501] zbesi routine is called. It uses a power series for small $z$, the asymptotic expansion for large $\text{abs}(z)$, the Miller algorithm normalized by the Wronskian and a Neumann series for intermediate magnitudes, and the uniform asymptotic expansions for $I_v(z)$ and $J_v(z)$ for large orders. Backward recurrence is used to generate sequences or reduce orders when necessary.

The calculations above are done in the right half plane and continued into the left half plane by the formula,

$$I_v(z \exp(\pm i\pi)) = \exp(\pm \pi v) I_v(z)$$

(valid when the real part of $z$ is positive). For negative $v$, the formula

$$I_{-v}(z) = I_v(z) + 2\pi \sin(\pi v) K_v(z)$$

is used, where $K_v(z)$ is the modified Bessel function of the second kind, evaluated using the AMOS routine zbesk.
References

[R501]

`scipy.special.hankel1(v, z) = <ufunc 'hankell'>`

Hankel function of the first kind

Parameters
- `v`: array_like
  Order (float).
- `z`: array_like
  Argument (float or complex).

Returns
- `out`: Values of the Hankel function of the first kind.

See also:
- `hankel1e` this function with leading exponential behavior stripped off.

Notes
A wrapper for the AMOS [R484] routine `zbesh`, which carries out the computation using the relation,

\[
H_v^{(1)}(z) = \frac{2}{\pi} \exp(-i\pi v/2) K_v(z \exp(-i\pi/2))
\]

where \(K_v\) is the modified Bessel function of the second kind. For negative orders, the relation

\[
H_{-v}^{(1)}(z) = H_v^{(1)}(z) \exp(i\pi v)
\]

is used.

References

[R484]

`scipy.special.hankel1e(v, z) = <ufunc 'hankelle'>`

Exponentially scaled Hankel function of the first kind

Defined as:

\[
hankelle(v, z) = hankell(v, z) \times \exp(-1j \times z)
\]

Parameters
- `v`: array_like
  Order (float).
- `z`: array_like
  Argument (float or complex).

Returns
- `out`: Values of the exponentially scaled Hankel function.

Notes
A wrapper for the AMOS [R485] routine `zbesh`, which carries out the computation using the relation,

\[
H_v^{(1)}(z) = \frac{2}{\pi} \exp(-i\pi v/2) K_v(z \exp(-i\pi/2))
\]

where \(K_v\) is the modified Bessel function of the second kind. For negative orders, the relation

\[
H_{-v}^{(1)}(z) = H_v^{(1)}(z) \exp(i\pi v)
\]

is used.
References

[R485]

`scipy.special.hankel2(v, z) <ufunc ‘hankel2’>`

Hankel function of the second kind

Parameters

- `v`: array_like
  Order (float).
- `z`: array_like
  Argument (float or complex).

Returns

- `out`: Values of the Hankel function of the second kind.

See also:

- `hankel2e` this function with leading exponential behavior stripped off.

Notes

A wrapper for the AMOS [R486] routine `zbesh`, which carries out the computation using the relation,

\[ H^{(2)}_v(z) = -\frac{2}{i\pi} \exp(i\pi v/2) K_v(z \exp(i\pi/2)) \]

where \( K_v \) is the modified Bessel function of the second kind. For negative orders, the relation

\[ H^{(2)}_{-v}(z) = H^{(2)}_v(z) \exp(-i\pi v) \]

is used.

References

[R486]

`scipy.special.hankel2e(v, z) <ufunc ‘hankel2e’>`

Exponentially scaled Hankel function of the second kind

Defined as:

\[
\text{hankel2e}(v, z) = \text{hankel2}(v, z) \times \exp(1j \times z)
\]

Parameters

- `v`: array_like
  Order (float).
- `z`: array_like
  Argument (float or complex).

Returns

- `out`: Values of the exponentially scaled Hankel function of the second kind.

Notes

A wrapper for the AMOS [R487] routine `zbesh`, which carries out the computation using the relation,

\[ H^{(2)}_v(z) = -\frac{2}{i\pi} \exp(i\pi v/2) K_v(z \exp(i\pi/2)) \]

where \( K_v \) is the modified Bessel function of the second kind. For negative orders, the relation

\[ H^{(2)}_{-v}(z) = H^{(2)}_v(z) \exp(-i\pi v) \]

is used.

References

[R487]

The following is not an universal function:
\texttt{scipy.special.lmbda(v, x)}

Jahnke-Emden Lambda function, \( \texttt{Lambdav(x)} \).

This function is defined as \[ R535 \],

\[ \Lambda_v(x) = \Gamma(v + 1) J_v \left( \frac{x}{2} \right)^v, \]

where \( \Gamma \) is the gamma function and \( J_v \) is the Bessel function of the first kind.

**Parameters**
- \( v \): float
  - Order of the Lambda function
- \( x \): float
  - Value at which to evaluate the function and derivatives

**Returns**
- \( vl \): ndarray
  - Values of \( \text{Lambda}_{vi}(x) \), for \( vi=v-\text{int}(v) \), \( vi=1+v-\text{int}(v) \), ..., \( vi=v \).
- \( dl \): ndarray
  - Derivatives \( \text{Lambda}_{vi}'(x) \), for \( vi=v-\text{int}(v) \), \( vi=1+v-\text{int}(v) \), ..., \( vi=v \).

**References**
- \[ R534 \], \[ R535 \]

**Zeros of Bessel Functions**

These are not universal functions:

\texttt{scipy.special.jnjp_zeros(nt)}

Compute zeros of integer-order Bessel functions \( J_n \) and \( J_n' \).

Results are arranged in order of the magnitudes of the zeros.

**Parameters**
- \( nt \): int
  - Number (\( \leq 1200 \)) of zeros to compute

**Returns**
- \( zo[l-1] \): ndarray
  - Value of the \( l \)th zero of \( J_n(x) \) and \( J_n'(x) \). Of length \( nt \).
- \( n[l-1] \): ndarray
  - Order of the \( J_n(x) \) or \( J_n'(x) \) associated with \( l \)th zero. Of length \( nt \).
m[l-1] : ndarray
    Serial number of the zeros of Jn(x) or Jn’(x) associated with lth zero. Of
    length n.

t[l-1] : ndarray
    0 if lth zero in zo is zero of Jn(x), 1 if it is a zero of Jn’(x). Of length n.

See also:
    jn_zeros, jnp_zeros

References
[R508]
scipy.special.jyn_zeros(n, nt)
    Compute nt zeros of Bessel functions Jn(x), Jn'(x), Yn(x), and Yn'(x).
    Returns 4 arrays of length nt, corresponding to the first nt zeros of Jn(x),
    Jn'(x), Yn(x), and Yn'(x), respectively.

    Parameters
    n : int
        Order of the Bessel functions
    nt : int
        Number (<=1200) of zeros to compute
    See jn_zeros, jnp_zeros, yn_zeros, ynp_zeros to get separate arrays.

References
[R510]
scipy.special.jn_zeros(n, nt)
    Compute zeros of integer-order Bessel function Jn(x).

    Parameters
    n : int
        Order of Bessel function
    nt : int
        Number of zeros to return

References
[R507]
scipy.special.jnp_zeros(n, nt)
    Compute zeros of integer-order Bessel function derivative Jn'(x).

    Parameters
    n : int
        Order of Bessel function
    nt : int
        Number of zeros to return

References
[R509]
scipy.special.yn_zeros(n, nt)
    Compute zeros of integer-order Bessel function Yn(x).

    Parameters
    n : int
        Order of Bessel function
    nt : int
        Number of zeros to return
References

[R595]

scipy.special.ynp_zeros(n, nt)
Compute zeros of integer-order Bessel function derivative Yn'(x).

Parameters
  n : int
    Order of Bessel function
  nt : int
    Number of zeros to return

References

[R596]

scipy.special.y0_zeros(nt, complex=False)
Compute nt zeros of Bessel function Y0(z), and derivative at each zero.
The derivatives are given by Y0'(z0) = -Y1(z0) at each zero z0.

Parameters
  nt : int
    Number of zeros to return
  complex : bool, default False
    Set to False to return only the real zeros; set to True to return only the
    complex zeros with negative real part and positive imaginary part. Note
    that the complex conjugates of the latter are also zeros of the function, but
    are not returned by this routine.

Returns
  z0n : ndarray
    Location of nth zero of Y0(z)
  y0pz0n : ndarray
    Value of derivative Y0'(z0) for nth zero

References

[R590]

scipy.special.y1_zeros(nt, complex=False)
Compute nt zeros of Bessel function Y1(z), and derivative at each zero.
The derivatives are given by Y1'(z1) = Y0(z1) at each zero z1.

Parameters
  nt : int
    Number of zeros to return
  complex : bool, default False
    Set to False to return only the real zeros; set to True to return only the
    complex zeros with negative real part and positive imaginary part. Note
    that the complex conjugates of the latter are also zeros of the function, but
    are not returned by this routine.

Returns
  z1n : ndarray
    Location of nth zero of Y1(z)
  y1pz1n : ndarray
    Value of derivative Y1'(z1) for nth zero

References

[R592]

scipy.special.y1p_zeros(nt, complex=False)
Compute nt zeros of Bessel derivative Y1'(z), and value at each zero.
The values are given by Y1(z1) at each z1 where Y1'(z1)=0.
Parameters

- `nt : int`
  Number of zeros to return
- `complex : bool, default False`
  Set to False to return only the real zeros; set to True to return only the complex zeros with negative real part and positive imaginary part. Note that the complex conjugates of the latter are also zeros of the function, but are not returned by this routine.

Returns

- `z1pn : ndarray`
  Location of nth zero of $Y_1'(z)$
- `y1z1pn : ndarray`
  Value of derivative $Y_1(z_1)$ for nth zero

References

[R593]

```
scipy.special.j0(x) = <ufunc 'j0'>
```

Bessel function of the first kind of order 0.

Parameters

- `x : array_like`
  Argument (float).

Returns

- `J : ndarray`
  Value of the Bessel function of the first kind of order 0 at $x$.

See also:

- `jv`: Bessel function of real order and complex argument.
- `spherical_jn`: spherical Bessel functions.

Notes

The domain is divided into the intervals [0, 5] and (5, infinity). In the first interval the following rational approximation is used:

$$J_0(x) \approx (w - r_1^2)(w - r_2^2) \frac{P_3(w)}{Q_8(w)},$$

where $w = x^2$ and $r_1, r_2$ are the zeros of $J_0$, and $P_3$ and $Q_8$ are polynomials of degrees 3 and 8, respectively.
In the second interval, the Hankel asymptotic expansion is employed with two rational functions of degree 6/6 and 7/7.

This function is a wrapper for the Cephes [R504] routine \( j_0 \). It should not to be confused with the spherical Bessel functions (see \( \text{spherical}_\text{jn} \)).

References

[R504]

\[
\text{scipy.special.} j_1(x) = \langle \text{ufunc } \text{\textquoteleft}j1\text{"} >
\]
Bessel function of the first kind of order 1.

Parameters

- \( x \) : array_like
  - Argument (float).

Returns

- \( J \) : ndarray
  - Value of the Bessel function of the first kind of order 1 at \( x \).

See also:

- \( jv \)
- \( \text{spherical}_\text{jn} \)
  spherical Bessel functions.

Notes

The domain is divided into the intervals \([0, 8]\) and \((8, \infty)\). In the first interval a 24 term Chebyshev expansion is used. In the second, the asymptotic trigonometric representation is employed using two rational functions of degree 5/5.

This function is a wrapper for the Cephes [R505] routine \( j_1 \). It should not to be confused with the spherical Bessel functions (see \( \text{spherical}_\text{jn} \)).

References

[R505]

\[
\text{scipy.special.} y_0(x) = \langle \text{ufunc } \text{\textquoteleft}y0\text{"} >
\]
Bessel function of the second kind of order 0.

Parameters

- \( x \) : array_like
  - Argument (float).

Returns

- \( Y \) : ndarray
  - Value of the Bessel function of the second kind of order 0 at \( x \).

See also:

- \( j0, yv \)

Notes

The domain is divided into the intervals \([0, 5]\) and \((5, \infty)\). In the first interval a rational approximation \( R(x) \) is employed to compute,

\[
Y_0(x) = R(x) + \frac{2 \log(x) J_0(x)}{\pi},
\]

where \( J_0 \) is the Bessel function of the first kind of order 0.

In the second interval, the Hankel asymptotic expansion is employed with two rational functions of degree 6/6 and 7/7.

This function is a wrapper for the Cephes [R589] routine \( y0 \).
**References**

[R589]

```
scipy.special.y1(x) = <ufunc 'y1'>
```

Bessel function of the second kind of order 1.

**Parameters**
- `x`: array_like

**Returns**
- `Y`: ndarray
  Value of the Bessel function of the second kind of order 1 at `x`.

**See also:**
- `j1`, `yn`, `yv`

**Notes**

The domain is divided into the intervals [0, 8] and (8, infinity). In the first interval a 25 term Chebyshev expansion is used, and computing $J_1$ (the Bessel function of the first kind) is required. In the second, the asymptotic trigonometric representation is employed using two rational functions of degree 5/5.

This function is a wrapper for the Cephes [R591] routine `y1`.

**References**

[R591]

```
scipy.special.i0(x) = <ufunc 'i0'>
```

Modified Bessel function of order 0.

Defined as,

$$I_0(x) = \sum_{k=0}^{\infty} \frac{(x^2/4)^k}{(k!)^2} = J_0(\nu x),$$

where $J_0$ is the Bessel function of the first kind of order 0.

**Parameters**
- `x`: array_like

**Returns**
- `I`: ndarray
  Value of the modified Bessel function of order 0 at `x`.

**See also:**
- `iv`, `i0e`

**Notes**

The range is partitioned into the two intervals [0, 8] and (8, infinity). Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephes [R491] routine `i0`.

**References**

[R491]

```
scipy.special.i0e(x) = <ufunc 'i0e'>
```

Exponentially scaled modified Bessel function of order 0.

Defined as:

$$i0e(x) = \exp(-|x|) \times i0(x).$$
Parameters  
  \(x\) : array_like  
  Argument (float)

Returns  
  \(I\) : ndarray  
  Value of the exponentially scaled modified Bessel function of order 0 at \(x\).

See also:
  \(iv, i0\)

Notes
The range is partitioned into the two intervals \([0, 8]\) and \((8, \infty)\). Chebyshev polynomial expansions are employed in each interval. The polynomial expansions used are the same as those in \(i0\), but they are not multiplied by the dominant exponential factor.

This function is a wrapper for the Cephes \([R492]\) routine \(i0e\).

References
\([R492]\)

```
special.i0(x) = ufunc 'i0'
```
Modified Bessel function of order 0.

Defined as,

\[
I_0(x) = \frac{1}{2} x \sum_{k=0}^{\infty} \frac{(x^2/4)^k}{k!(k + 1)!} = -iJ_1(ix),
\]

where \(J_1\) is the Bessel function of the first kind of order 1.

Parameters  
  \(x\) : array_like  
  Argument (float)

Returns  
  \(I\) : ndarray  
  Value of the modified Bessel function of order 0 at \(x\).

See also:
  \(iv, i0e\)

Notes
The range is partitioned into the two intervals \([0, 8]\) and \((8, \infty)\). Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephes \([R493]\) routine \(i1\).

References
\([R493]\)

```
special.i1(x) = ufunc 'i1'
```
Modified Bessel function of order 1.

Defined as,

\[
I_1(x) = \frac{1}{2} x \sum_{k=0}^{\infty} \frac{(x^2/4)^k}{k!(k + 1)!} = -iJ_1(ix),
\]

where \(J_1\) is the Bessel function of the first kind of order 1.

Parameters  
  \(x\) : array_like  
  Argument (float)

Returns  
  \(I\) : ndarray  
  Value of the modified Bessel function of order 1 at \(x\).

See also:
  \(iv, i1e\)

Notes
The range is partitioned into the two intervals \([0, 8]\) and \((8, \infty)\). Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephes \([R493]\) routine \(i1e\).

References
\([R493]\)

```
special.i1e(x) = ufunc 'i1e'
```
Exponentially scaled modified Bessel function of order 1.

Defined as:

\[
\text{i1e}(x) = \exp(-|x|) \times i1(x)
\]

Parameters  
  \(x\) : array_like  
  Argument (float)

Returns  
  \(I\) : ndarray  
  Value of the exponentially scaled modified Bessel function of order 1 at \(x\).
See also:

$iv, il$

Notes
The range is partitioned into the two intervals $[0, 8]$ and $(8, \infty)$. Chebyshev polynomial expansions are employed in each interval. The polynomial expansions used are the same as those in $i1$, but they are not multiplied by the dominant exponential factor.

This function is a wrapper for the Cephes $[R494]$ routine $i1e$.

References

$[R494]$

scipy.special.k0(x) = <ufunc ‘k0’>
Modified Bessel function of the second kind of order 0, $K_0$.

This function is also sometimes referred to as the modified Bessel function of the third kind of order 0.

Parameters

x : array_like

Returns

K : ndarray
Value of the modified Bessel function $K_0$ at $x$.

See also:

$kv, k0e$

Notes
The range is partitioned into the two intervals $[0, 2]$ and $(2, \infty)$. Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephes $[R515]$ routine $k0$.

References

$[R515]$

scipy.special.k0e(x) = <ufunc ‘k0e’>
Exponentially scaled modified Bessel function $K$ of order 0
Defined as:

\[ k0e(x) = \exp(x) \times k0(x). \]

Parameters

x : array_like

Returns

K : ndarray
Value of the exponentially scaled modified Bessel function $K$ of order 0 at $x$.

See also:

$kv, k0$

Notes
The range is partitioned into the two intervals $[0, 2]$ and $(2, \infty)$. Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephes $[R516]$ routine $k0e$.  

5.26. Special functions (scipy.special) 1583
References

scipy.special.k1(x) = <ufunc 'k1'>
Modified Bessel function of the second kind of order 1, \( K_1(x) \).

**Parameters**
x : array_like

**Returns**
K : ndarray
Value of the modified Bessel function \( K \) of order 1 at \( x \).

**See also:**
\( kv, k1e \)

**Notes**
The range is partitioned into the two intervals \([0, 2]\) and \((2, \infty)\). Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephes [R517] routine \( k1 \).

References

scipy.special.k1e(x) = <ufunc 'k1e'>
Exponentially scaled modified Bessel function \( K \) of order 1

Defined as:

\[ k1e(x) = \exp(x) \times k1(x) \]

**Parameters**
x : array_like

**Returns**
K : ndarray
Value of the exponentially scaled modified Bessel function \( K \) of order 1 at \( x \).

**See also:**
\( kv, k1 \)

**Notes**
The range is partitioned into the two intervals \([0, 2]\) and \((2, \infty)\). Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephes [R518] routine \( k1e \).

ik0  \int(k0(t)/t, t=x..\infty)\,dt

scipy.special.besselpoly(a, lmb, nu) = <ufunc ‘besselpoly’>
Weighted integral of a Bessel function.

\int_0^1 x^\lambda J_\nu(2ax) \,dx

where \( J_\nu \) is a Bessel function and \( \lambda = lmb, \nu = nu \).

Derivatives of Bessel Functions

\textbf{jvp}(v, z[, n])  
Compute nth derivative of Bessel function \( J_v(z) \) with respect to \( z \).

\textbf{yvp}(v, z[, n])  
Compute nth derivative of Bessel function \( Y_v(z) \) with respect to \( z \).

\textbf{kvp}(v, z[, n])  
Compute nth derivative of real-order modified Bessel function \( K_v(z) \).

\textbf{ivp}(v, z[, n])  
Compute nth derivative of modified Bessel function \( I_v(z) \) with respect to \( z \).

\textbf{h1vp}(v, z[, n])  
Compute nth derivative of Hankel function \( H_1v(z) \) with respect to \( z \).

\textbf{h2vp}(v, z[, n])  
Compute nth derivative of Hankel function \( H_2v(z) \) with respect to \( z \).

\textbf{jvp}(v, z, n=1)  
Compute nth derivative of Bessel function \( J_v(z) \) with respect to \( z \).
**Parameters**
- v : float
  Order of Bessel function
- z : complex
  Argument at which to evaluate the derivative
- n : int, default 1
  Order of derivative

**Notes**
The derivative is computed using the relation DLFM 10.6.7 [R514].

**References**
[R513], [R514]

`scipy.special.yvp(v, z, n=1)`
Compute nth derivative of Bessel function $Y_v(z)$ with respect to $z$.

**Parameters**
- v : float
  Order of Bessel function
- z : complex
  Argument at which to evaluate the derivative
- n : int, default 1
  Order of derivative

**Notes**
The derivative is computed using the relation DLFM 10.6.7 [R600].

**References**
[R599], [R600]

`scipy.special.kvp(v, z, n=1)`
Compute nth derivative of real-order modified Bessel function $K_v(z)$.

$K_v(z)$ is the modified Bessel function of the second kind. Derivative is calculated with respect to $z$.

**Parameters**
- v : array_like of float
  Order of Bessel function
- z : array_like of complex
  Argument at which to evaluate the derivative
- n : int

**Returns**
- out : ndarray
  Order of derivative. Default is first derivative.
  The results

**Notes**
The derivative is computed using the relation DLFM 10.29.5 [R531].

**References**
[R530], [R531]

**Examples**
Calculate multiple values at order 5:
Calculate for a single value at multiple orders:

```python
>>> kvp((4, 4.5, 5), 1)
array([-184.0309, -568.9585, -1849.0354])
```

scipy.special.ivp(v, z, n=1)
Compute nth derivative of modified Bessel function Iv(z) with respect to z.

**Parameters**
- v : array_like of float
  Order of Bessel function
- z : array_like of complex
  Argument at which to evaluate the derivative
- n : int, default 1
  Order of derivative

**Notes**
The derivative is computed using the relation DLMF 10.29.5 \[R503\].

**References**
[R502], [R503]

scipy.special.h1vp(v, z, n=1)
Compute nth derivative of Hankel function H1v(z) with respect to z.

**Parameters**
- v : float
  Order of Hankel function
- z : complex
  Argument at which to evaluate the derivative
- n : int, default 1
  Order of derivative

**Notes**
The derivative is computed using the relation DLMF 10.6.7 \[R481\].

**References**
[R480], [R481]

scipy.special.h2vp(v, z, n=1)
Compute nth derivative of Hankel function H2v(z) with respect to z.

**Parameters**
- v : float
  Order of Hankel function
- z : complex
  Argument at which to evaluate the derivative
- n : int, default 1
  Order of derivative

**Notes**
The derivative is computed using the relation DLMF 10.6.7 \[R483\].

[R482], [R483]

Spherical Bessel Functions

\[ \text{spherical\_jn}(n, z, \text{derivative}) \]
Spherical Bessel function of the first kind or its derivative.

\[ \text{spherical\_yn}(n, z, \text{derivative}) \]
Spherical Bessel function of the second kind or its derivative.

\[ \text{spherical\_in}(n, z, \text{derivative}) \]
Modified spherical Bessel function of the first kind or its derivative.

\[ \text{spherical\_kn}(n, z, \text{derivative}) \]
Modified spherical Bessel function of the second kind or its derivative.

scipy.special.spherical_jn\((n, z, \text{derivative}=False)\)
Spherical Bessel function of the first kind or its derivative.

Defined as [R578],

\[
j_n(z) = \sqrt{\frac{\pi}{2z}} J_{n+1/2}(z),
\]

where \(J_n\) is the Bessel function of the first kind.

**Parameters**

- **n**: int, array_like
  Order of the Bessel function \((n \geq 0)\).
- **z**: complex or float, array_like
  Argument of the Bessel function.
- **derivative**: bool, optional
  If True, the value of the derivative (rather than the function itself) is returned.

**Returns**

- **jn**: ndarray

**Notes**

For real arguments greater than the order, the function is computed using the ascending recurrence [R579]. For small real or complex arguments, the definitional relation to the cylindrical Bessel function of the first kind is used.

The derivative is computed using the relations [R580],

\[
j_n'(z) = j_{n-1}(z) - \frac{n + 1}{z} j_n(z).
\]

\[
j_0'(z) = -j_1(z)
\]

New in version 0.18.0.

**References**

[R578], [R579], [R580]

scipy.special.spherical_yn\((n, z, \text{derivative}=False)\)
Spherical Bessel function of the second kind or its derivative.

Defined as [R583],

\[
y_n(z) = \sqrt{\frac{\pi}{2z}} Y_{n+1/2}(z),
\]

where \(Y_n\) is the Bessel function of the second kind.
Parameters

- **n**: int, array_like
  
  Order of the Bessel function ($n \geq 0$).

- **z**: complex or float, array_like
  
  Argument of the Bessel function.

- **derivative**: bool, optional
  
  If True, the value of the derivative (rather than the function itself) is returned.

Returns

- **yn**: ndarray

Notes

For real arguments, the function is computed using the ascending recurrence [R584]. For complex arguments, the definitional relation to the cylindrical Bessel function of the second kind is used.

The derivative is computed using the relations [R585],

\[ y'_n = y_{n-1} - \frac{n+1}{2}y_n. \]
\[ y'_0 = -y_1 \]

New in version 0.18.0.

References

[R583], [R584], [R585]

```py
scipy.special.spherical_in(n, z, derivative=False)
```

Modified spherical Bessel function of the first kind or its derivative.

Defined as [R576],

\[ i_n(z) = \sqrt{\frac{\pi}{2z}} I_{n+1/2}(z), \]

where $I_n$ is the modified Bessel function of the first kind.

Parameters

- **n**: int, array_like
  
  Order of the Bessel function ($n \geq 0$).

- **z**: complex or float, array_like
  
  Argument of the Bessel function.

- **derivative**: bool, optional
  
  If True, the value of the derivative (rather than the function itself) is returned.

Returns

- **in**: ndarray

Notes

The function is computed using its definitional relation to the modified cylindrical Bessel function of the first kind.

The derivative is computed using the relations [R577],

\[ i'_n = i_{n-1} - \frac{n+1}{2}i_n. \]
\[ i'_1 = i_0 \]

New in version 0.18.0.
scipy.special.spherical_kn(n, z, derivative=False)

Modified spherical Bessel function of the second kind or its derivative.

Defined as \( k_n(z) = \sqrt{\frac{\pi}{2z}} K_{n+1/2}(z) \),

where \( K_n \) is the modified Bessel function of the second kind.

**Parameters**

- **n**: int, array_like
  Order of the Bessel function (\( n \geq 0 \)).
- **z**: complex or float, array_like
  Argument of the Bessel function.
- **derivative**: bool, optional
  If True, the value of the derivative (rather than the function itself) is returned.

**Returns**

- **kn**: ndarray

**Notes**

The function is computed using its definitional relation to the modified cylindrical Bessel function of the second kind.

The derivative is computed using the relations:
\[
\frac{d}{dz} k_n(z) = -k_n - \frac{n+1}{2} k_n.
\]

New in version 0.18.0.

**References**

[R581], [R582]
**Returns**

- **jn**: ndarray
  - Argument at which to evaluate
  - Value of \( j_0(x) \), ..., \( j_n(x) \)

- **jnp**: ndarray
  - First derivative \( j_0'(x) \), ..., \( j_n'(x) \)

**Notes**

The computation is carried out via backward recurrence, using the relation DLMF 10.51.1 [R565].

Wrapper for a Fortran routine created by Shanjie Zhang and Jianming Jin [R564].

**References**

[R564], [R565]

```
scipy.special.riccati_yn(n, x)
```

Compute Ricatti-Bessel function of the second kind and its derivative.

The Ricatti-Bessel function of the second kind is defined as \( x y_n(x) \), where \( y_n \) is the spherical Bessel function of the second kind of order \( n \).

This function computes the value and first derivative of the function for all orders up to and including \( n \).

**Parameters**

- **n**: int
  - Maximum order of function to compute
- **x**: float

**Returns**

- **yn**: ndarray
  - Argument at which to evaluate
  - Value of \( y_0(x) \), ..., \( y_n(x) \)
- **ynp**: ndarray
  - First derivative \( y_0'(x) \), ..., \( y_n'(x) \)

**Notes**

The computation is carried out via ascending recurrence, using the relation DLMF 10.51.1 [R567].

Wrapper for a Fortran routine created by Shanjie Zhang and Jianming Jin [R566].

**References**

[R566], [R567]

**Struve Functions**

```
struve(v, x)
modstruve(v, x)
itrstruve0(x)
it2struve0(x)
itmodstru0(x)
```

<table>
<thead>
<tr>
<th>Struve function</th>
</tr>
</thead>
<tbody>
<tr>
<td>struve(v, x)</td>
</tr>
<tr>
<td>modstruve(v, x)</td>
</tr>
<tr>
<td>itrstruve0(x)</td>
</tr>
<tr>
<td>it2struve0(x)</td>
</tr>
<tr>
<td>itmodstru0(x)</td>
</tr>
</tbody>
</table>

```
scipy.special.struve(v, x) = <ufunc 'struve'>
```

Struve function.

Return the value of the Struve function of order \( v \) at \( x \). The Struve function is defined as,

\[
H_v(x) = (z/2)^{v+1} \sum_{n=0}^{\infty} \frac{(-1)^n (z/2)^{2n}}{\Gamma(n + \frac{3}{2})\Gamma(n + v + \frac{3}{2})},
\]

where \( \Gamma \) is the gamma function.
**Parameters**

- **v** : array_like
  Order of the Struve function (float).
- **x** : array_like
  Argument of the Struve function (float; must be positive unless \( v \) is an integer).

**Returns**

- **H** : ndarray
  Value of the Struve function of order \( v \) at \( x \).

**See also:**

modstruve

**Notes**

Three methods discussed in [R586] are used to evaluate the Struve function:

- power series
- expansion in Bessel functions (if \(|z| < |v| + 20\))
- asymptotic large-\( z \) expansion (if \( z \geq 0.7v + 12 \))

Rounding errors are estimated based on the largest terms in the sums, and the result associated with the smallest error is returned.

**References**

[R586]

```
scipy.special.modstruve(v, x) = <ufunc 'modstruve'>
```

Modified Struve function.

Return the value of the modified Struve function of order \( v \) at \( x \). The modified Struve function is defined as,

\[
L_v(x) = -i \exp(-\pi v/2) H_v(x),
\]

where \( H_v \) is the Struve function.

**Parameters**

- **v** : array_like
  Order of the modified Struve function (float).
- **x** : array_like
  Argument of the Struve function (float; must be positive unless \( v \) is an integer).

**Returns**

- **L** : ndarray
  Value of the modified Struve function of order \( v \) at \( x \).

**See also:**

struve

**Notes**

Three methods discussed in [R545] are used to evaluate the function:

- power series
- expansion in Bessel functions (if \(|z| < |v| + 20\))
- asymptotic large-\( z \) expansion (if \( z \geq 0.7v + 12 \))

Rounding errors are estimated based on the largest terms in the sums, and the result associated with the smallest error is returned.

**References**

[R545]
scipy.special.itstruve0(x) = <ufunc ‘itstruve0’>
Integral of the Struve function of order 0.

\[ I = \int_0^x H_0(t) \, dt \]

**Parameters**
- `x`: array_like
  Upper limit of integration (float).

**Returns**
- `I`: ndarray
  The integral of \( H_0 \) from 0 to \( x \).

See also:
- struve

Notes
Wrapper for a Fortran routine created by Shanjie Zhang and Jianming Jin [R498].

References
[R498]

scipy.special.it2struve0(x) = <ufunc ‘it2struve0’>
Integral related to the Struve function of order 0.

Returns the integral,

\[ \int_x^\infty \frac{H_0(t)}{t} \, dt \]

where \( H_0 \) is the Struve function of order 0.

**Parameters**
- `x`: array_like
  Lower limit of integration.

**Returns**
- `I`: ndarray
  The value of the integral.

See also:
- struve

Notes
Wrapper for a Fortran routine created by Shanjie Zhang and Jianming Jin [R495].

References
[R495]

scipy.special.itmodstruve0(x) = <ufunc ‘itmodstruve0’>
Integral of the modified Struve function of order 0.

\[ I = \int_0^x L_0(t) \, dt \]

**Parameters**
- `x`: array_like
  Upper limit of integration (float).

**Returns**
- `I`: ndarray
  The integral of \( L_0 \) from 0 to \( x \).

Notes
Wrapper for a Fortran routine created by Shanjie Zhang and Jianming Jin [R497].

scipy.special.bdtr(k, n, p) = <ufunc 'bdtr'>

Binomial distribution cumulative distribution function.

Sum of the terms 0 through k of the Binomial probability density.

\[
bdtr(k, n, p) = \sum_{j=0}^{k} \binom{n}{j} p^j (1 - p)^{n-j}
\]

**Parameters**
- **k**: array_like
  - Number of successes (int).
- **n**: array_like
  - Number of events (int).
- **p**: array_like
  - Probability of success in a single event (float).

**Returns**
- **y**: ndarray
  - Probability of k or fewer successes in n independent events with success probabilities of p.
Notes

The terms are not summed directly; instead the regularized incomplete beta function is employed, according to the formula,

\[ \text{bdtr}(k, n, p) = I_{1-p}(n-k, k+1). \]

Wrapper for the Cephes [R416] routine \texttt{bdtr}.

References

[R416]

\texttt{scipy.special.bdtrc}(k, n, p) = <ufunc 'bdtrc'>

Binomial distribution survival function.

Sum of the terms \( k + 1 \) through \( n \) of the binomial probability density,

\[ \text{bdtrc}(k, n, p) = \sum_{j=k+1}^{n} \binom{n}{j} p^j (1 - p)^{n-j} \]

Parameters

- \( k \) : array_like
  - Number of successes (int).
- \( n \) : array_like
  - Number of events (int).
- \( p \) : array_like
  - Probability of success in a single event.

Returns

- \( y \) : ndarray
  - Probability of \( k + 1 \) or more successes in \( n \) independent events with success probabilities of \( p \).

See also:

\texttt{bdtr}, \texttt{betainc}

Notes

The terms are not summed directly; instead the regularized incomplete beta function is employed, according to the formula,

\[ \text{bdtrc}(k, n, p) = I_p(k+1, n-k). \]

Wrapper for the Cephes [R417] routine \texttt{bdtrc}.

References

[R417]

\texttt{scipy.special.bdtri}(k, n, y) = <ufunc 'bdtri'>

Inverse function to \texttt{bdtr} with respect to \( p \).

Finds the event probability \( p \) such that the sum of the terms 0 through \( k \) of the binomial probability density is equal to the given cumulative probability \( y \).

Parameters

- \( k \) : array_like
  - Number of successes (float).
- \( n \) : array_like
  - Number of events (float).
- \( y \) : array_like
  - Cumulative probability (probability of \( k \) or fewer successes in \( n \) events).

Returns

- \( p \) : ndarray
  - Event probability (probability of \( k + 1 \) or more successes in \( n \) events).
The event probability such that $bdtr(k, n, p) = y$.

See also:

$bdtr, betaincinv$

Notes

The computation is carried out using the inverse beta integral function and the relation:

$$1 - p = \text{betaincinv}(n - k, k + 1, y).$$

Wrapper for the Cephes [R418] routine $bdtri$.

References

[R418]

scipy.special.$bdtrik$ ($y, n, p$) = <ufunc ‘bdtrik’>

Inverse function to $bdtr$ with respect to $k$.

Finds the number of successes $k$ such that the sum of the terms 0 through $k$ of the Binomial probability density for $n$ events with probability $p$ is equal to the given cumulative probability $y$.

Parameters

$y$: array_like

Cumulative probability (probability of $k$ or fewer successes in $n$ events).

$n$: array_like

Number of events (float).

$p$: array_like

Success probability (float).

Returns

$k$: ndarray

The number of successes $k$ such that $bdtr(k, n, p) = y$.

See also:

$bdtr$

Notes

Formula 26.5.24 of [R419] is used to reduce the binomial distribution to the cumulative incomplete beta distribution.

Computation of $k$ involves a search for a value that produces the desired value of $y$. The search relies on the monotonicity of $y$ with $k$.

Wrapper for the CDFLIB [R420] Fortran routine $cdffin$.

References

[R419], [R420]

scipy.special.$bdtrin$ ($k, y, p$) = <ufunc ‘bdtrin’>

Inverse function to $bdtr$ with respect to $n$.

Finds the number of events $n$ such that the sum of the terms 0 through $k$ of the Binomial probability density for events with probability $p$ is equal to the given cumulative probability $y$.

Parameters

$k$: array_like

Number of successes (float).

$y$: array_like

Cumulative probability (probability of $k$ or fewer successes in $n$ events).

$p$: array_like

Success probability (float).

Returns

$n$: ndarray

Success probability (float).
The number of events \( n \) such that \( \text{bdtr}(k, n, p) = y \).

See also:

\texttt{bdtr}

Notes

Formula 26.5.24 of [R421] is used to reduce the binomial distribution to the cumulative incomplete beta distribution.

Computation of \( n \) involves a search for a value that produces the desired value of \( y \). The search relies on the monotonicity of \( y \) with \( n \).

Wrapper for the CDFLIB [R422] Fortran routine \texttt{cdfbin}.

References

[R421], [R422]

\texttt{scipy.special.bdtr(a, b, x) = <ufunc 'bdtr'>}

Cumulative density function of the beta distribution.

Returns the integral from zero to \( x \) of the beta probability density function,

\[
I = \int_0^x \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} t^{a-1} (1-t)^{b-1} \, dt
\]

where \( \Gamma \) is the gamma function.

Parameters

- \( a \) : array_like
  - Shape parameter \( (a > 0) \).
- \( b \) : array_like
  - Shape parameter \( (b > 0) \).
- \( x \) : array_like

Returns

- \( I \) : ndarray
  - Cumulative density function of the beta distribution with parameters \( a \) and \( b \) at \( x \).

See also:

\texttt{betainc}

Notes

This function is identical to the incomplete beta integral function \texttt{betainc}.

Wrapper for the Cephes [R429] routine \texttt{btdtr}.

References

[R429]

\texttt{scipy.special.btdtri(a, b, p) = <ufunc 'btdtri'>}

The \( p \)-th quantile of the beta distribution.

This function is the inverse of the beta cumulative distribution function, \texttt{btstdr}, returning the value of \( x \) for which \( \text{btstdr}(a, b, x) = p \), or

\[
p = \int_0^x \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} t^{a-1} (1-t)^{b-1} \, dt
\]

Parameters

- \( a \) : array_like
Shape parameter \((a > 0)\).

\[ b : \text{array_like} \]
Shape parameter \((b > 0)\).

\[ p : \text{array_like} \]
Cumulative probability, in \([0, 1]\).

\[ x : \text{ndarray} \]
The quantile corresponding to \(p\).

**See also:**

betaincinv, btdtr

**Notes**
The value of \(x\) is found by interval halving or Newton iterations.

Wrapper for the Cephes [R430] routine inchi, which solves the equivalent problem of finding the inverse of the incomplete beta integral.

**References**

[R430]

scipy.special.btdtria \((p, b, x) = \text{ufunc ‘btdtria’}\)

Inverse of btdtr with respect to \(a\).

This is the inverse of the beta cumulative distribution function, btdtr, considered as a function of \(a\), returning the value of \(a\) for which btdtr\((a, b, x) = p\), or

\[
p = \int_0^x \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} t^{a-1}(1-t)^{b-1} dt
\]

**Parameters**

\[ p : \text{array_like} \]
Cumulative probability, in \([0, 1]\).

\[ b : \text{array_like} \]
Shape parameter \((b > 0)\).

\[ x : \text{array_like} \]

**Returns**

\[ a : \text{ndarray} \]
The quantile, in \([0, 1]\).

The value of the shape parameter \(a\) such that btdtr\((a, b, x) = p\).

**See also:**

btdtr Cumulative density function of the beta distribution.

btdtri Inverse with respect to \(x\).

btdtrib Inverse with respect to \(b\).

**Notes**
Wrapper for the CDFLIB [R431] Fortran routine cdffbet.

The cumulative distribution function \(p\) is computed using a routine by DiDinato and Morris [R432]. Computation of \(a\) involves a search for a value that produces the desired value of \(p\). The search relies on the monotonicity of \(p\) with \(a\).

**References**

[R431], [R432]

scipy.special.btdtrib \((a, p, x) = \text{ufunc ‘btdtrib’}\)

Inverse of btdtr with respect to \(b\).
This is the inverse of the beta cumulative distribution function, \( btdtr \), considered as a function of \( b \), returning the value of \( b \) for which \( btdtr(a, b, x) = p \), or

\[
p = \int_0^x \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} t^{a-1}(1-t)^{b-1} \, dt
\]

**Parameters**
- \( a \): array_like
  - Shape parameter \((a > 0)\).
- \( p \): array_like
  - Cumulative probability, in [0, 1].
- \( x \): array_like
  - The quantile, in [0, 1].

**Returns**
- \( b \): ndarray
  - The value of the shape parameter \( b \) such that \( btdtr(a, b, x) = p \).

See also:
- \( btdtr \) Cumulative density function of the beta distribution.
- \( btdtri \) Inverse with respect to \( x \).
- \( btdtria \) Inverse with respect to \( a \).

**Notes**
Wrapper for the CDFLIB [R433] Fortran routine \( cdfbet \).

The cumulative distribution function \( p \) is computed using a routine by DiDinato and Morris [R434]. Computation of \( b \) involves a search for a value that produces the desired value of \( p \). The search relies on the monotonicity of \( p \) with \( b \).

**References**
[R433], [R434]

\[
\text{scipy.special.fdtz}(dfn, dfd, x) = \text{ufunc `fdtr'>}
\]

F cumulative distribution function.

Returns the value of the cumulative density function of the F-distribution, also known as Snedecor’s F-distribution or the Fisher-Snedecor distribution.

The F-distribution with parameters \( d_n \) and \( d_d \) is the distribution of the random variable,

\[
X = \frac{U_n/d_n}{U_d/d_d}
\]

where \( U_n \) and \( U_d \) are random variables distributed \( \chi^2 \), with \( d_n \) and \( d_d \) degrees of freedom, respectively.

**Parameters**
- \( dfn \): array_like
  - First parameter (positive float).
- \( dfd \): array_like
  - Second parameter (positive float).
- \( x \): array_like
  - Argument (nonnegative float).

**Returns**
- \( y \): ndarray
  - The CDF of the F-distribution with parameters \( dfn \) and \( dfd \) at \( x \).

**Notes**
The regularized incomplete beta function is used, according to the formula,

\[
F(d_n, d_d; x) = I_{xd_n/(d_d+xd_d)}(d_n/2, d_d/2).
\]

Wrapper for the Cephes [R464] routine \( fdtr \).
References

[R464]

scipy.special.fdtrc(dfn, dfd, x) = <ufunc ‘fdtrc’>

F survival function.

Returns the complemented F-distribution function (the integral of the density from $x$ to infinity).

Parameters

dfn : array_like
    First parameter (positive float).
dfd : array_like
    Second parameter (positive float).
x : array_like
    Argument (nonnegative float).

Returns

y : ndarray
    The complemented F-distribution function with parameters $dfn$ and $dfd$ at $x$.

See also:

fdtr

Notes

The regularized incomplete beta function is used, according to the formula,

\[ F(d_n, d_d; x) = I_{d_d/(d_d+x d_n)}(d_d/2, d_n/2). \]

Wrapper for the Cephes [R465] routine fdtrc.

References

[R465]

scipy.special.fdtri(dfn, dfd, p) = <ufunc ‘fdtri’>

The $p$-th quantile of the F-distribution.

This function is the inverse of the F-distribution CDF, $fdtr$, returning the $x$ such that $fdtr(dfn, dfd, x) = p$.

Parameters

dfn : array_like
    First parameter (positive float).
dfd : array_like
    Second parameter (positive float).
p : array_like
    Cumulative probability, in [0, 1].

Returns

x : ndarray
    The quantile corresponding to $p$.

Notes

The computation is carried out using the relation to the inverse regularized beta function, $I^{-1}_x(a, b)$. Let $z = I^{-1}_p(d_d/2, d_n/2)$. Then,

\[ x = \frac{d_d(1 - z)}{d_n z}. \]

If $p$ is such that $x < 0.5$, the following relation is used instead for improved stability: let $z' = I^{-1}_{1-p}(d_n/2, d_d/2)$. Then,

\[ x = \frac{d_d z'}{d_n(1 - z')}. \]

Wrapper for the Cephes [R466] routine fdtri.
References

[R466]

scipy.special.fdtridfd(dfn, p, x) = <ufunc ‘fdtridfd’>
Inverse to fdtr vs dfd
Finds the F density argument dfd such that fdtr(dfn, dfd, x) == p.

scipy.special.gdtr(a, b, x) = <ufunc ‘gdtr’>
Gamma distribution cumulative density function.
Returns the integral from zero to x of the gamma probability density function,
\[ F = \int_0^x \frac{a^b}{\Gamma(b)} t^{b-1} e^{-at} dt, \]
where \( \Gamma \) is the gamma function.

Parameters

- a : array_like
  The rate parameter of the gamma distribution, sometimes denoted \( \beta \) (float).
  It is also the reciprocal of the scale parameter \( \theta \).
- b : array_like
  The shape parameter of the gamma distribution, sometimes denoted \( \alpha \) (float).
- x : array_like
  The quantile (upper limit of integration; float).

Returns

- F : ndarray
  The CDF of the gamma distribution with parameters a and b evaluated at x.

See also:

gdtrc 1 - CDF of the gamma distribution.

Notes
The evaluation is carried out using the relation to the incomplete gamma integral (regularized gamma function).
Wrapper for the Cephes [R472] routine gdtr.

References

[R472]

scipy.special.gdtrc(a, b, x) = <ufunc ‘gdtrc’>
Gamma distribution survival function.
Integral from x to infinity of the gamma probability density function,
\[ F = \int_x^\infty \frac{a^b}{\Gamma(b)} t^{b-1} e^{-at} dt, \]
where \( \Gamma \) is the gamma function.

Parameters

- a : array_like
  The rate parameter of the gamma distribution, sometimes denoted \( \beta \) (float).
  It is also the reciprocal of the scale parameter \( \theta \).
- b : array_like
  The shape parameter of the gamma distribution, sometimes denoted \( \alpha \) (float).
- x : array_like
  The quantile (lower limit of integration; float).

Returns

- F : ndarray
  The quantile (lower limit of integration; float).
The survival function of the gamma distribution with parameters $a$ and $b$
evaluated at $x$.

See also:
gdtr, gdtri

Notes
The evaluation is carried out using the relation to the incomplete gamma integral (regularized gamma function).
Wrapper for the Cephes [R473] routine gdtrc.

References
[R473]

scipy.special.gdtria($p$, $b$, $x$, out=None) = <ufunc 'gdtria'>
Inverse of gdtr vs a.
Returns the inverse with respect to the parameter $a$ of $p = gdtr(a, b, x)$, the cumulative distribution function of the gamma distribution.

Parameters
\[ p : \text{array_like} \]
Probability values.
\[ b : \text{array_like} \]
\[ b \] parameter values of \( gdtr(a, b, x) \). \( b \) is the “shape” parameter of the gamma distribution.
\[ x : \text{array_like} \]
Nonnegative real values, from the domain of the gamma distribution.
\[ \text{out} : \text{ndarray, optional} \]
If a fourth argument is given, it must be a numpy.ndarray whose size matches the broadcast result of \( a \), \( b \) and \( x \). \( \text{out} \) is then the array returned by the function.

Returns
\[ a : \text{ndarray} \]
Values of the \( a \) parameter such that \( p = gdtr(a, b, x) \). \( 1/a \) is the “scale” parameter of the gamma distribution.

See also:
gdtr CDF of the gamma distribution.
gdtrib Inverse with respect to \( b \) of \( gdtr(a, b, x) \).
gdtrix Inverse with respect to \( x \) of \( gdtr(a, b, x) \).

Notes
Wrapper for the CDFLIB [R474] Fortran routine cdfigam.
The cumulative distribution function \( p \) is computed using a routine by DiDinato and Morris [R475]. Computation of \( a \) involves a search for a value that produces the desired value of \( p \). The search relies on the monotonicity of \( p \) with \( a \).

References
[R474], [R475]

Examples
First evaluate \( gdtr \).
>>> from scipy.special import gdtr, gdtria
>>> p = gdtr(1.2, 3.4, 5.6)
>>> print(p)
0.94378087442

Verify the inverse.

>>> gdtria(p, 3.4, 5.6)
1.2

scipy.special.gdtrib(a, p, x, out=None) = <ufunc 'gdtrib'>
Inverse of gdtr vs b.

Returns the inverse with respect to the parameter b of p = gdtr(a, b, x), the cumulative distribution function of the gamma distribution.

Parameters

- **a**: array_like
  - a parameter values of gdtr(a, b, x). 1/a is the “scale” parameter of the gamma distribution.

- **p**: array_like
  - Probability values.

- **x**: array_like
  - Nonnegative real values, from the domain of the gamma distribution.

- **out**: ndarray, optional
  - If a fourth argument is given, it must be a numpy.ndarray whose size matches the broadcast result of a, b and x. out is then the array returned by the function.

Returns

- **b**: ndarray
  - Values of the b parameter such that p = gdtr(a, b, x). b is the “shape” parameter of the gamma distribution.

See also:

gdtr CDF of the gamma distribution.
gdtria Inverse with respect to a of gdtr(a, b, x).
gdtrix Inverse with respect to x of gdtr(a, b, x).

Notes

Wrapper for the CDFLIB [R476] Fortran routine cdfgam.

The cumulative distribution function p is computed using a routine by DiDinato and Morris [R477]. Computation of b involves a search for a value that produces the desired value of p. The search relies on the monotonicity of p with b.

References

[R476], [R477]

Examples

First evaluate gdtr.

>>> from scipy.special import gdtr, gdtria
>>> p = gdtr(1.2, 3.4, 5.6)
>>> print(p)
0.94378087442

Verify the inverse.
scipy.special.gdtrix(a, b, p, out=None) = <ufunc ‘gdtrix’>
Inverse of \( gdtr \) vs \( x \).

Returns the inverse with respect to the parameter \( x \) of \( p = gdtr(a, b, x) \), the cumulative distribution function of the gamma distribution. This is also known as the \( p \)'th quantile of the distribution.

Parameters
- \( a \) : array_like
  \( a \) parameter values of \( gdtr(a, b, x) \). \( 1/a \) is the “scale” parameter of the gamma distribution.
- \( b \) : array_like
  \( b \) parameter values of \( gdtr(a, b, x) \). \( b \) is the “shape” parameter of the gamma distribution.
- \( p \) : array_like
  Probability values.
- \( out \) : ndarray, optional
  If a fourth argument is given, it must be a numpy.ndarray whose size matches the broadcast result of \( a, b \) and \( x \). \( out \) is then the array returned by the function.

Returns
- \( x \) : ndarray
  Values of the \( x \) parameter such that \( p = gdtr(a, b, x) \).

See also:
gdtr CDF of the gamma distribution.
gdtria Inverse with respect to \( a \) of \( gdtr(a, b, x) \).
gdtrib Inverse with respect to \( b \) of \( gdtr(a, b, x) \).

Notes
Wrapper for the CDFLIB \[R478\] Fortran routine \texttt{cdfgam}.
The cumulative distribution function \( p \) is computed using a routine by DiDinato and Morris \[R479\]. Computation of \( x \) involves a search for a value that produces the desired value of \( p \). The search relies on the monotonicity of \( p \) with \( x \).

References
\[R478\], \[R479\]

Examples
First evaluate \( gdtr \).

>>> from scipy.special import gdtr, gdtrix
>>> p = gdtr(1.2, 3.4, 5.6)
>>> print(p)
0.94378087442

Verify the inverse.

>>> gdtrix(1.2, 3.4, p)
5.5999999999999996

scipy.special.nbdtr(k, n, p) = <ufunc ‘nbdtr’>
Negative binomial cumulative distribution function.
Returns the sum of the terms 0 through k of the negative binomial distribution probability mass function,

\[ F = \sum_{j=0}^{k} \binom{n + j - 1}{j} p^n (1 - p)^j. \]

In a sequence of Bernoulli trials with individual success probabilities p, this is the probability that k or fewer failures precede the nth success.

**Parameters**
- **k**: array_like
  - The maximum number of allowed failures (nonnegative int).
- **n**: array_like
  - The target number of successes (positive int).
- **p**: array_like
  - Probability of success in a single event (float).

**Returns**
- **F**: ndarray
  - The probability of k or fewer failures before n successes in a sequence of events with individual success probability p.

**See also:**

*nbdtrc*

**Notes**

If floating point values are passed for k or n, they will be truncated to integers.

The terms are not summed directly; instead the regularized incomplete beta function is employed, according to the formula,

\[ nbdtr(k, n, p) = I_p(n, k + 1). \]

Wrapper for the Cephes [R546] routine *nbdtr*.

**References**

[R546]

scipy.special.nbdtrc(k, n, p) = <ufunc 'nbdtrc'>

Negative binomial survival function.

Returns the sum of the terms k + 1 to infinity of the negative binomial distribution probability mass function,

\[ F = \sum_{j=k+1}^{\infty} \binom{n + j - 1}{j} p^n (1 - p)^j. \]

In a sequence of Bernoulli trials with individual success probabilities p, this is the probability that more than k failures precede the nth success.

**Parameters**
- **k**: array_like
  - The maximum number of allowed failures (nonnegative int).
- **n**: array_like
  - The target number of successes (positive int).
- **p**: array_like
  - Probability of success in a single event (float).

**Returns**
- **F**: ndarray
  - The probability of k + 1 or more failures before n successes in a sequence of events with individual success probability p.
Notes

If floating point values are passed for k or n, they will be truncated to integers.

The terms are not summed directly; instead the regularized incomplete beta function is employed, according to the formula,

\[ \text{nbdtrc}(k, n, p) = I_{1-p}(k + 1, n). \]

Wrapper for the Cephes [R547] routine nbdtrc.

References

[R547]
scipy.special.nbdtri (k, n, y) = <ufunc 'nbdtri'>

Inverse of nbdtr vs p.

Returns the inverse with respect to the parameter p of y = nbdtr(k, n, p), the negative binomial cumulative distribution function.

Parameters

- k : array_like
  The maximum number of allowed failures (nonnegative int).
- n : array_like
  The target number of successes (positive int).
- y : array_like

Returns

- p : ndarray
  The probability of k or fewer failures before n successes (float).

Notes

Wrapper for the Cephes [R548] routine nbdtri.

References

[R548]
scipy.special.nbdtrik (y, n, p) = <ufunc 'nbdtrik'>

Inverse of nbdtr vs k.

Returns the inverse with respect to the parameter k of y = nbdtr(k, n, p), the negative binomial cumulative distribution function.

Parameters

- y : array_like
  The probability of k or fewer failures before n successes (float).
- n : array_like
  The target number of successes (positive int).
- p : array_like

Returns

- k : ndarray
  The maximum number of allowed failures such that nbdtr(k, n, p) = y.
SciPy Reference Guide, Release 1.0.0

nbdtrin Inverse with respect to $n$ of nbdtr($k, n, p$).

Notes
Wrapper for the CDFLIB [R549] Fortran routine cdfnbn.
Formula 26.5.26 of [R550],

$$
\sum_{j=k+1}^{\infty} \binom{n+j-1}{j} p^n (1-p)^j = I_{1-p}(k+1,n),
$$

is used to reduce calculation of the cumulative distribution function to that of a regularized incomplete beta $I$.
Computation of $n$ involves a search for a value that produces the desired value of $y$. The search relies on the monotonicity of $y$ with $k$.

References
[R549], [R550]

scipy.special.nbdtrin($k, y, p$) = <ufunc ‘nbdtrin’>
Inverse of nbdtr vs $n$.

Returns the inverse with respect to the parameter $n$ of $y = nbdtr(k, n, p)$, the negative binomial cumulative distribution function.

Parameters
- $k$ : array_like
  The maximum number of allowed failures (nonnegative int).
- $y$ : array_like
  The probability of $k$ or fewer failures before $n$ successes (float).
- $p$ : array_like
  Probability of success in a single event (float).

Returns
- $n$ : ndarray
  The number of successes $n$ such that $nbdtr(k, n, p) = y$.

See also:
nbdtr Cumulative distribution function of the negative binomial.
nbdtri Inverse with respect to $p$ of nbdtr($k, n, p$).
nbdtrik Inverse with respect to $k$ of nbdtr($k, n, p$).

Notes
Wrapper for the CDFLIB [R551] Fortran routine cdfnbn.
Formula 26.5.26 of [R552],

$$
\sum_{j=k+1}^{\infty} \binom{n+j-1}{j} p^n (1-p)^j = I_{1-p}(k+1,n),
$$

is used to reduce calculation of the cumulative distribution function to that of a regularized incomplete beta $I$.
Computation of $n$ involves a search for a value that produces the desired value of $y$. The search relies on the monotonicity of $y$ with $n$.

References
[R551], [R552]

scipy.special.ncfdtr($dfn, dfd, nc, f$) = <ufunc ‘ncfdtr’>
Cumulative distribution function of the non-central F distribution.
The non-central F describes the distribution of,
\[ Z = \frac{X/d_n}{Y/d_d} \]
where \(X\) and \(Y\) are independently distributed, with \(X\) distributed non-central \(\chi^2\) with noncentrality parameter \(nc\) and \(d_n\) degrees of freedom, and \(Y\) distributed \(\chi^2\) with \(d_d\) degrees of freedom.

**Parameters**
- \(dfn\) : array_like
  Degrees of freedom of the numerator sum of squares. Range (0, inf).
- \(dfd\) : array_like
  Degrees of freedom of the denominator sum of squares. Range (0, inf).
- \(nc\) : array_like
  Noncentrality parameter. Should be in range (0, 1e4).
- \(f\) : array_like
  Quantiles, i.e. the upper limit of integration.

**Returns**
- \(cdf\) : float or ndarray
  The calculated CDF. If all inputs are scalar, the return will be a float. Otherwise it will be an array.

See also:
- \(ncfdtri\) Quantile function; inverse of \(ncfdtr\) with respect to \(f\).
- \(ncfdtridfd\) Inverse of \(ncfdtr\) with respect to \(dfd\).
- \(ncfdtridfn\) Inverse of \(ncfdtr\) with respect to \(dfn\).
- \(ncfdtrinc\) Inverse of \(ncfdtr\) with respect to \(nc\).

**Notes**
Wrapper for the CDFLIB [R553] Fortran routine \texttt{cdffnc}.

The cumulative distribution function is computed using Formula 26.6.20 of [R554]:
\[
F(d_n, d_d, nc, f) = \sum_{j=0}^{\infty} e^{-nc/2} \left( \frac{nc/2}{j!} \right)^j I_x \left( \frac{d_n}{2} + j, \frac{d_d}{2} \right),
\]
where \(I\) is the regularized incomplete beta function, and \(x = fd_n/(fd_n + d_d)\).

The computation time required for this routine is proportional to the noncentrality parameter \(nc\). Very large values of this parameter can consume immense computer resources. This is why the search range is bounded by 10,000.

**References**
[R553], [R554]

**Examples**
```python
>>> from scipy import special
>>> from scipy import stats
>>> import matplotlib.pyplot as plt

Plot the CDF of the non-central F distribution, for nc=0. Compare with the F-distribution from scipy.stats:
```
```python
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, ncf_stats, 'b-', lw=3)
>>> ax.plot(x, ncf_special, 'r-')
>>> plt.show()
```

**scipy.special.ncfdtridfd**

Calculate degrees of freedom (denominator) for the noncentral F-distribution. This is the inverse with respect to dfd of ncfdtr. See ncfdtr for more details.

**Parameters**
- **dfn**: array_like
  Degrees of freedom of the numerator sum of squares. Range (0, inf).
- **p**: array_like
  Value of the cumulative distribution function. Must be in the range [0, 1].
- **nc**: array_like
  Noncentrality parameter. Should be in range (0, 1e4).
- **f**: array_like
  Quantiles, i.e. the upper limit of integration.

**Returns**
- **dfd**: float
  Degrees of freedom of the denominator sum of squares.

**See also:**
- **ncfdtr** CDF of the non-central F distribution.
- **ncfdtri** Quantile function; inverse of ncfdtr with respect to f.
- **ncfdtridfn** Inverse of ncfdtr with respect to dfn.
- **ncfdtrinc** Inverse of ncfdtr with respect to nc.

**Notes**

The value of the cumulative noncentral F distribution is not necessarily monotone in either degrees of freedom. There thus may be two values that provide a given CDF value. This routine assumes monotonicity and will find an arbitrary one of the two values.
Examples

```python
>>> from scipy.special import ncfdr, ncfdridfd
```

Compute the CDF for several values of $\text{dfd}$:

```python
>>> dfd = [1, 2, 3]
>>> p = ncfdr(2, dfd, 0.25, 15)
>>> p
array([0.8097138, 0.93020416, 0.96787852])
```

Compute the inverse. We recover the values of $\text{dfd}$, as expected:

```python
>>> ncfdridfd(2, p, 0.25, 15)
array([1., 2., 3.])
```

```python
scipy.special.ncfdtrifdfn(p, dfd, nc, f) = <ufunc 'ncfdtrifdfn'>
```

Calculate degrees of freedom (numerator) for the noncentral F-distribution. This is the inverse with respect to $\text{dfn}$ of $\text{ncfdtr}$. See $\text{ncfdtr}$ for more details.

- **Parameters**
  - `p`: array_like Value of the cumulative distribution function. Must be in the range [0, 1].
  - `dfd`: array_like Degrees of freedom of the denominator sum of squares. Range (0, inf).
  - `nc`: array_like Noncentrality parameter. Should be in range (0, 1e4).
  - `f`: float Quantiles, i.e. the upper limit of integration.

- **Returns**
  - `dfn`: float Degrees of freedom of the numerator sum of squares.

See also:

- `ncfdtr` CDF of the non-central F distribution.
- `ncfdtri` Quantile function; inverse of `ncfdtr` with respect to $f$.
- `ncfdtridfd` Inverse of `ncfdtr` with respect to $\text{dfd}$.
- `ncfdtrinc` Inverse of `ncfdtr` with respect to $\text{nc}$.

Notes

The value of the cumulative noncentral F distribution is not necessarily monotone in either degrees of freedom. There thus may be two values that provide a given CDF value. This routine assumes monotonicity and will find an arbitrary one of the two values.

Examples

```python
>>> from scipy.special import ncfdr, ncfdridfn
```

Compute the CDF for several values of $\text{dfn}$:

```python
>>> dfn = [1, 2, 3]
>>> p = ncfdr(dfn, 2, 0.25, 15)
>>> p
array([0.92562363, 0.93020416, 0.93188394])
```

Compute the inverse. We recover the values of $\text{dfn}$, as expected:
```python
>>> ncfdtridfn(p, 2, 0.25, 15)
array([ 1., 2., 3.])
```

**scipy.special.ncfdtri** *(dfn,dfd,nc,p) = <ufunc ‘ncfdtri’>*

Inverse with respect to \( f \) of the CDF of the non-central F distribution.

See ncfdtr for more details.

**Parameters**
- \( \text{dfn} \) : array_like
  - Degrees of freedom of the numerator sum of squares. Range \((0, \infty)\).
- \( \text{dfd} \) : array_like
  - Degrees of freedom of the denominator sum of squares. Range \((0, \infty)\).
- \( \text{nc} \) : array_like
  - Noncentrality parameter. Should be in range \((0, 1e4)\).
- \( \text{p} \) : array_like
  - Value of the cumulative distribution function. Must be in the range \([0, 1]\).

**Returns**
- \( f \) : float
  - Quantiles, i.e. the upper limit of integration.

See also:
- ncfdtr \quad CDF of the non-central F distribution.
- ncfdtridfd \quad Inverse of ncfdtr with respect to dfd.
- ncfdtridfn \quad Inverse of ncfdtr with respect to dfn.
- ncfdtrinc \quad Inverse of ncfdtr with respect to nc.

**Examples**

```python
>>> from scipy.special import ncfdtr, ncfdtri
```

Compute the CDF for several values of \( f \):

```python
>>> f = [0.5, 1, 1.5]
>>> p = ncfdtr(2, 3, 1.5, f)
>>> p
array([0.20782291, 0.36107392, 0.47345752])
```

Compute the inverse. We recover the values of \( f \), as expected:

```python
>>> ncfdtri(2, 3, 1.5, p)
array([0.5, 1. , 1.5])
```

**scipy.special.ncfdtrinc** *(dfn,dfd,p,f) = <ufunc ‘ncfdtrinc’>*

Calculate non-centrality parameter for non-central F distribution.

This is the inverse with respect to \( nc \) of ncfdtr. See ncfdtr for more details.

**Parameters**
- \( \text{dfn} \) : array_like
  - Degrees of freedom of the numerator sum of squares. Range \((0, \infty)\).
- \( \text{dfd} \) : array_like
  - Degrees of freedom of the denominator sum of squares. Range \((0, \infty)\).
- \( \text{p} \) : array_like
  - Value of the cumulative distribution function. Must be in the range \([0, 1]\).
- \( \text{f} \) : array_like
  - Quantiles, i.e. the upper limit of integration.

**Returns**
- \( \text{nc} \) : float
  - Noncentrality parameter.

See also:
ncfdtr CDF of the non-central F distribution.
ncfdtri Quantile function; inverse of \texttt{ncfdtr} with respect to \( f \).
nxfdtridfd Inverse of \texttt{ncfdtr} with respect to \( df_d \).
nxfdtridfn Inverse of \texttt{ncfdtr} with respect to \( df_n \).

\textbf{Examples}

```python
>>> from scipy.special import ncfdtr, ncfdtrinc

Compute the CDF for several values of \( nc \):

```python
>>> nc = [0.5, 1.5, 2.0]
>>> p = ncfdtr(2, 3, nc, 15)
>>> p
array([ 0.96309246, 0.94327955, 0.93304098])
```

Compute the inverse. We recover the values of \( nc \), as expected:

```python
>>> ncfdtrinc(2, 3, p, 15)
array([ 0.5, 1.5, 2.0])
```

\texttt{scipy.special.nctdtr}(\( df, nc, t \)) = <ufunc 'nctdtr'>
Cumulative distribution function of the non-central \( t \) distribution.

\textbf{Parameters}

- \( df \) : array_like
  Degrees of freedom of the distribution. Should be in range (0, inf).
- \( nc \) : array_like
  Noncentrality parameter. Should be in range (-1e6, 1e6).
- \( t \) : array_like
  Quantiles, i.e. the upper limit of integration.

\textbf{Returns}

- \( cdf \) : float or ndarray
  The calculated CDF. If all inputs are scalar, the return will be a float. Otherwise it will be an array.

\textbf{See also:}

- \texttt{nctdtrit} Inverse CDF (iCDF) of the non-central \( t \) distribution.
- \texttt{nctdtridf} Calculate degrees of freedom, given CDF and iCDF values.
- \texttt{nctdtrinc} Calculate non-centrality parameter, given CDF iCDF values.

\textbf{Examples}

```python
>>> from scipy import special
>>> from scipy import stats
>>> import matplotlib.pyplot as plt

Plot the CDF of the non-central \( t \) distribution, for \( nc=0 \). Compare with the \( t \)-distribution from scipy.stats:

```python
>>> x = np.linspace(-5, 5, num=500)
>>> df = 3
>>> nct_stats = stats.t.cdf(x, df)
>>> nct_special = special.nctdtr(df, 0, x)

>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, nct_stats, 'b-', lw=3)
>>> ax.plot(x, nct_special, 'r-', color='r')
>>> plt.show()
```
scipy.special.nctdtridf \( (p, nc, t) = \text{ufunc 'nctdtridf'} \)
Calculate degrees of freedom for non-central t distribution.
See nctdtr for more details.

Parameters

- \( p \) : array_like
  CDF values, in range (0, 1].
- \( nc \) : array_like
  Noncentrality parameter. Should be in range (-1e6, 1e6).
- \( t \) : array_like
  Quantiles, i.e. the upper limit of integration.

scipy.special.nctdtrit \( (df, nc, p) = \text{ufunc 'nctdtrit'} \)
Inverse cumulative distribution function of the non-central t distribution.
See nctdtr for more details.

Parameters

- \( df \) : array_like
  Degrees of freedom of the distribution. Should be in range (0, inf).
- \( nc \) : array_like
  Noncentrality parameter. Should be in range (-1e6, 1e6).
- \( p \) : array_like
  CDF values, in range (0, 1].

scipy.special.nctdtrinc \( (df, p, t) = \text{ufunc 'nctdtrinc'} \)
Calculate non-centrality parameter for non-central t distribution.
See nctdtr for more details.

Parameters

- \( df \) : array_like
  Degrees of freedom of the distribution. Should be in range (0, inf).
- \( p \) : array_like
  CDF values, in range (0, 1].
- \( t \) : array_like
  Quantiles, i.e. the upper limit of integration.

scipy.special.nrdtrimn \( (p, x, std) = \text{ufunc 'nrdtrimn'} \)
Calculate mean of normal distribution given other params.

Parameters

- \( p \) : array_like
CDF values, in range (0, 1].

\[ x : \text{array_like} \]
Quantiles, i.e. the upper limit of integration.

\[ \text{std} : \text{array_like} \]
Standard deviation.

**Returns**

\[ \text{mn} : \text{float or ndarray} \]
The mean of the normal distribution.

**See also:**

\[ \text{ndtrimn}, \text{ndtr} \]

**scipy.special.ndtrisd** \( p, x, \text{mn} \) = <ufunc ‘ndtrisd’>
Calculate standard deviation of normal distribution given other params.

**Parameters**

\[ p : \text{array_like} \]
CDF values, in range (0, 1].

\[ x : \text{array_like} \]
Quantiles, i.e. the upper limit of integration.

\[ \text{mn} : \text{float or ndarray} \]
The mean of the normal distribution.

**Returns**

\[ \text{std} : \text{array_like} \]
Standard deviation.

**See also:**

\[ \text{ndtristd}, \text{ndtr} \]

**scipy.special.pdtr** \( k, m \) = <ufunc ‘pdtr’>
Poisson cumulative distribution function

Returns the sum of the first \( k \) terms of the Poisson distribution: \( \sum \text{exp}(-m) * m^{j} / j! \). Arguments must both be positive and \( k \) an integer.

**scipy.special.pdtrc** \( k, m \) = <ufunc ‘pdtrc’>
Poisson survival function

Returns the sum of the terms from \( k+1 \) to infinity of the Poisson distribution: \( \sum \text{exp}(-m) * m^{j} / j! \). \( k \) must be a nonnegative integer and \( m \) between 0 and 1.

**scipy.special.pdtri** \( k, y \) = <ufunc ‘pdtri’>
Inverse to **pdtr** vs \( m \)

Returns the Poisson variable \( m \) such that the sum from 0 to \( k \) of the Poisson density is equal to the given probability \( y \): calculated by \( \text{gammainc}(k+1, y) \). \( k \) must be a nonnegative integer and \( y \) between 0 and 1.

**scipy.special.pdtrik** \( p, m \) = <ufunc ‘pdtrik’>
Inverse to **pdtr** vs \( k \)

Returns the quantile \( k \) such that \( \text{pdtr}(k, m) = p \)

**scipy.special.stdtr** \( df, t \) = <ufunc ‘stdtr’>
Student t distribution cumulative density function

Returns the integral from minus infinity to \( t \) of the Student t distribution with \( df > 0 \) degrees of freedom:

\[ \frac{\text{gamma}(\frac{df+1}{2})/\sqrt{df\pi}\times\text{gamma}(\frac{df}{2})}{\text{integral}((1+x**2/df)**\left(-\frac{df}{2-1/2}), x=-\infty..t)\times\left(\frac{df+1}{2}\right)/\sqrt{df\pi}\times\text{gamma}(\frac{df}{2})} \]

**scipy.special.stdtridf** \( p, t \) = <ufunc ‘stdtridf’>
Inverse of **stdtr** vs \( df \)

Returns the argument \( df \) such that \( \text{stdtr}(df, t) \) is equal to \( p \).
scipy.special.stdtrit(df, p) = <ufunc 'stdtrit'>
Inverse of stdtr vs t

Returns the argument \( t \) such that stdtr(df, t) is equal to \( p \).

scipy.special.chdtr(v, x) = <ufunc 'chdtr'>
Chi square cumulative distribution function

Returns the area under the left hand tail (from 0 to \( x \)) of the Chi square probability density function with \( v \) degrees of freedom:

\[
\frac{1}{2^v \Gamma(v/2)} \int_0^x t^{(v/2)-1} \exp(-t/2) \, dt
\]

scipy.special.chdtrc(v, x) = <ufunc 'chdtrc'>
Chi square survival function

Returns the area under the right hand tail (from \( x \) to infinity) of the Chi square probability density function with \( v \) degrees of freedom:

\[
\frac{1}{2^v \Gamma(v/2)} \int_x^\infty t^{(v/2)-1} \exp(-t/2) \, dt
\]

scipy.special.chdtri(v, p) = <ufunc 'chdtri'>
Inverse to chdtrc

Returns the argument \( x \) such that chdtrc(v, x) == p.

scipy.special.chdtriv(p, x) = <ufunc 'chdtriv'>
Inverse to chdtr

Returns the argument \( v \) such that chdtr(v, x) == p.

scipy.special.ndtr(x) = <ufunc 'ndtr'>
Gaussian cumulative distribution function.

Returns the area under the standard Gaussian probability density function, integrated from minus infinity to \( x \)

\[
\frac{1}{\sqrt{2\pi}} \int_{-\infty}^x \exp(-t^2/2) \, dt
\]

Parameters
- x : array_like, real or complex

Returns
- ndarray
  - Argument
  - The value of the normal CDF evaluated at \( x \)

See also:
- erf, erfc, scipy.stats.norm, log_ndtr

scipy.special.log_ndtr(x) = <ufunc 'log_ndtr'>
Logarithm of Gaussian cumulative distribution function.

Returns the log of the area under the standard Gaussian probability density function, integrated from minus infinity to \( x \):

\[
\log\left(\frac{1}{\sqrt{2\pi}} \int_{-\infty}^x \exp(-t^2/2) \, dt\right)
\]

Parameters
- x : array_like, real or complex

Returns
- ndarray
  - Argument
  - The value of the log of the normal CDF evaluated at \( x \)
SciPy Reference Guide, Release 1.0.0

See also:

- *erf*, *erfc*, *scipy.stats.norm*, *ndtr*

**scipy.special.ndtri**(*y*) = *ufunc* ‘ndtri’

Inverses of *ndtr* vs *x*

Returns the argument *x* for which the area under the Gaussian probability density function (integrated from minus infinity to *x*) is equal to *y*.

**scipy.special.chndtr**(*x*, *df*, *nc*) = *ufunc* ‘chndtr’

Non-central chi square cumulative distribution function

**scipy.special.chndtridf**(*x*, *p*, *nc*) = *ufunc* ‘chndtridf’

Inverse to *chndtr* vs *df*

**scipy.special.chndtrinc**(*x*, *df*, *p*) = *ufunc* ‘chndtrinc’

Inverse to *chndtr* vs *nc*

**scipy.special.chndtrix**(*p*, *df*, *nc*) = *ufunc* ‘chndtrix’

Inverse to *chndtr* vs *x*

**scipy.special.smirnov**(*n*, *e*) = *ufunc* ‘smirnov’

Kolmogorov-Smirnov complementary cumulative distribution function

Returns the exact Kolmogorov-Smirnov complementary cumulative distribution function (Dn+ or Dn-) for a one-sided test of equality between an empirical and a theoretical distribution. It is equal to the probability that the maximum difference between a theoretical distribution and an empirical one based on *n* samples is greater than *e*.

**scipy.special.smirnovi**(*n*, *y*) = *ufunc* ‘smirnovi’

Inverse to *smirnov*

Returns *e* such that *smirnov(n, e) = y*.

**scipy.special.kolmogorov**(*y*) = *ufunc* ‘kolmogorov’

Complementary cumulative distribution function of Kolmogorov distribution

Returns the complementary cumulative distribution function of Kolmogorov’s limiting distribution (Kn* for large *n*) of a two-sided test for equality between an empirical and a theoretical distribution. It is equal to the (limit as *n*->infinity of the) probability that sqrt(*n*) * max absolute deviation > *y*.

**scipy.special.kolmogi**(*p*) = *ufunc* ‘kolmogi’

Inverse function to *kolmogorov*

Returns *y* such that *kolmogorov(y) == p*.

**scipy.special.tklmbda**(*x*, *lmbda*) = *ufunc* ‘tklmbda’

Tukey-Lambda cumulative distribution function

**scipy.special.logit**(*x*) = *ufunc* ‘logit’

Logit ufunc for ndarrays.

The logit function is defined as logit(p) = log(p/(1-p)). Note that logit(0) = -inf, logit(1) = inf, and logit(p) for p<0 or p>1 yields nan.

**Parameters**

- *x*: ndarray

**Returns**

- *out*: ndarray

The ndarray to apply logit to element-wise.

An ndarray of the same shape as *x*. Its entries are logit of the corresponding entry of *x*.

See also:

- *expit*
Notes
As a ufunc logit takes a number of optional keyword arguments. For more information see ufuncs
New in version 0.10.0.

Examples

```python
>>> from scipy.special import logit, expit
>>> logit([0, 0.25, 0.5, 0.75, 1])
array([-inf, -1.09861229, 0. , 1.09861229, inf])
```

expit is the inverse of logit:

```python
>>> expit(logit([0.1, 0.75, 0.999]))
array([ 0.1 , 0.75 , 0.999])
```

Plot logit(x) for x in [0, 1]:

```python
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(0, 1, 501)
>>> y = logit(x)
>>> plt.plot(x, y)
>>> plt.grid()
>>> plt.ylim(-6, 6)
>>> plt.xlabel('x')
>>> plt.title('logit(x)')
>>> plt.show()
```

```
scipy.special.expit(x) = <ufunc 'expit'>
```

Exipt ufunc for ndarrays.

The expit function, also known as the logistic function, is defined as expit(x) = 1/(1+exp(-x)). It is the inverse of the logit function.

**Parameters**

- `x`: ndarray

**Returns**

- `out`: ndarray
  The ndarray to apply expit to element-wise.
An ndarray of the same shape as x. Its entries are expit of the corresponding entry of x.

See also:
logit

Notes
As a ufunc expit takes a number of optional keyword arguments. For more information see ufuncs

New in version 0.10.0.

Examples

```python
>>> from scipy.special import expit, logit

>>> expit([-np.inf, -1.5, 0, 1.5, np.inf])
array([ 0. , 0.18242552, 0.5 , 0.81757448, 1. ])

logit is the inverse of expit:

>>> logit(expit([-2.5, 0, 3.1, 5.0]))
array([-2.5, 0. , 3.1, 5. ])

Plot expit(x) for x in [-6, 6]:

```python
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-6, 6, 121)
>>> y = expit(x)
>>> plt.plot(x, y)
>>> plt.grid()
>>> plt.xlim(-6, 6)
>>> plt.xlabel('x')
>>> plt.title('expit(x)')
>>> plt.show()
```
The Box-Cox transformation is:

\[
y = \begin{cases} 
\frac{x^{\lambda} - 1}{\lambda} & \text{if } \lambda \neq 0 \\
\log(x) & \text{if } \lambda = 0
\end{cases}
\]

Returns \textit{nan} if \(x < 0\). Returns \textit{-inf} if \(x = 0\) and \(\lambda < 0\).

**Parameters**
- \(x\) : array_like
  Data to be transformed.
- \(\lambda\) : array_like
  Power parameter of the Box-Cox transform.

**Returns**
- \(y\) : array
  Transformed data.

**Notes**
New in version 0.14.0.

**Examples**

```python
>>> from scipy.special import boxcox
>>> boxcox([1, 4, 10], 2.5)
array([ 0. , 12.4 , 126.09110641])
>>> boxcox(2, [0, 1, 2])
array([ 0.69314718, 1. , 1.5])
```

scipy.special.boxcox1p(x, \(\lambda\)) = <ufunc 'boxcox1p'>
Compute the Box-Cox transformation of \(1 + x\).

The Box-Cox transformation computed by boxcox1p is:

\[
y = \begin{cases} 
\frac{(1+x)^{\lambda} - 1}{\lambda} & \text{if } \lambda \neq 0 \\
\log(1+x) & \text{if } \lambda = 0
\end{cases}
\]

Returns \textit{nan} if \(x < -1\). Returns \textit{-inf} if \(x = -1\) and \(\lambda < 0\).

**Parameters**
- \(x\) : array_like
  Data to be transformed.
- \(\lambda\) : array_like
  Power parameter of the Box-Cox transform.

**Returns**
- \(y\) : array
  Transformed data.

**Notes**
New in version 0.14.0.

**Examples**

```python
>>> from scipy.special import boxcox1p
>>> boxcox1p(1e-4, [0, 0.5, 1])
array([ 9.99950003e-05, 9.99975001e-05, 1.00000000e-04])
>>> boxcox1p([0.01, 0.1], 0.25)
array([ 0.00996272, 0.09645476])
```

scipy.special.inv_boxcox(y, \(\lambda\)) = <ufunc 'inv_boxcox'>
Compute the inverse of the Box-Cox transformation.

Find \(x\) such that:
.. code-block:: python

    y = (x**lmbda - 1) / lmbda  
        if lmbda != 0
    log(x)  
        if lmbda == 0

**Parameters**

- **y**: array_like
  Data to be transformed.
- **lmbda**: array_like
  Power parameter of the Box-Cox transform.

**Returns**

- **x**: array
  Transformed data.

**Notes**

New in version 0.16.0.

**Examples**

```python
>>> from scipy.special import boxcox, inv_boxcox
>>> y = boxcox([1, 4, 10], 2.5)
>>> inv_boxcox(y, 2.5)
array([1., 4., 10.])
```

.. _boxcox1p:

```python
scipy.special.inv_boxcox1p(y, lmbda) = <ufunc 'inv_boxcox1p'>
```

Compute the inverse of the Box-Cox transformation.

Find \( x \) such that:

\[
    y = \frac{(1+x)^{lmbda} - 1}{lmbda} \quad \text{if } lmbda \neq 0
\]

\[
    \log(1+x) \quad \text{if } lmbda = 0
\]

**Parameters**

- **y**: array_like
  Data to be transformed.
- **lmbda**: array_like
  Power parameter of the Box-Cox transform.

**Returns**

- **x**: array
  Transformed data.

**Notes**

New in version 0.16.0.

**Examples**

```python
>>> from scipy.special import boxcox1p, inv_boxcox1p
>>> y = boxcox1p([1, 4, 10], 2.5)
>>> inv_boxcox1p(y, 2.5)
array([1., 4., 10.])
```

### Information Theory Functions

- `entr(x)`: Elementwise function for computing entropy.
- `rel_entr(x, y)`: Elementwise function for computing relative entropy.
- `kl_div(x, y)`: Elementwise function for computing Kullback-Leibler divergence.
- `huber(delta, r)`: Huber loss function.

Continued on next page
Table 5.256 – continued from previous page

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pseudo_huber(delta, r)</code></td>
<td>Pseudo-Huber loss function.</td>
</tr>
</tbody>
</table>

**scipy.special.entr(x) = <ufunc ‘entr’>**

Elementwise function for computing entropy.

\[
\text{entr}(x) = \begin{cases} 
-x \log(x) & x > 0 \\
0 & x = 0 \\
-\infty & \text{otherwise}
\end{cases}
\]

**Parameters**
- `x` : ndarray

**Returns**
- `res` : ndarray

Input array.

The value of the elementwise entropy function at the given points `x`.

**See also:**
- `kl_div`, `rel_entr`

**Notes**
This function is concave.

New in version 0.15.0.

**scipy.special.rel_entr(x, y) = <ufunc ‘rel_entr’>**

Elementwise function for computing relative entropy.

\[
\text{rel}_\text{entr}(x, y) = \begin{cases} 
x \log(x/y) & x > 0, y > 0 \\
0 & x = 0, y \geq 0 \\
\infty & \text{otherwise}
\end{cases}
\]

**Parameters**
- `x` : ndarray
- `y` : ndarray

**Returns**
- `res` : ndarray

First input array.

Second input array.

Output array.

**See also:**
- `entr`, `kl_div`

**Notes**
This function is jointly convex in `x` and `y`.

New in version 0.15.0.

**scipy.special.kl_div(x, y) = <ufunc ‘kl_div’>**

Elementwise function for computing Kullback-Leibler divergence.

\[
\text{kl}_\text{div}(x, y) = \begin{cases} 
x \log(x/y) - x + y & x > 0, y > 0 \\
y & x = 0, y \geq 0 \\
\infty & \text{otherwise}
\end{cases}
\]

**Parameters**
- `x` : ndarray
- `y` : ndarray

First input array.
Returns  

res : ndarray  
Second input array.  
Output array.

See also:
entr, rel_entr

Notes
This function is non-negative and is jointly convex in x and y.
New in version 0.15.0.

scipy.special.huber (delta, r) = <ufunc ‘huber’>
Huber loss function.

\[
\text{huber}(\delta, r) = \begin{cases} 
\infty & \delta < 0 \\
\frac{1}{2} r^2 & 0 \leq \delta, |r| \leq \delta \\
\delta(|r| - \frac{1}{2}\delta) & \text{otherwise}
\end{cases}
\]

Parameters
delta : ndarray  
Input array, indicating the quadratic vs. linear loss changepoint.

r : ndarray  
Input array, possibly representing residuals.

Returns  

res : ndarray  
The computed Huber loss function values.

Notes
This function is convex in r.
New in version 0.15.0.

scipy.special.pseudo_huber (delta, r) = <ufunc ‘pseudo_huber’>
Pseudo-Huber loss function.

\[
\text{pseudo\_huber}(\delta, r) = \delta^2 \left( \sqrt{1 + \left( \frac{r}{\delta} \right)^2} - 1 \right)
\]

Parameters
delta : ndarray  
Input array, indicating the soft quadratic vs. linear loss changepoint.

r : ndarray  
Input array, possibly representing residuals.

Returns  

res : ndarray  
The computed Pseudo-Huber loss function values.

Notes
This function is convex in r.
New in version 0.15.0.

Gamma and Related Functions

gamma(z)  
Gamma function.

gammaln(x, /[, out, where, casting, order, ...])  
Logarithm of the absolute value of the Gamma function.

loggamma(z[, out])  
Principal branch of the logarithm of the Gamma function.

scipy.special.gamma(z) = <ufunc ‘gamma’>

Gamma function.

\[
\Gamma(z) = \int_0^\infty x^{z-1}e^{-x}dx = (z-1)!
\]

The gamma function is often referred to as the generalized factorial since $z\gamma(z) = \gamma(z+1)$ and $\gamma(n+1) = n!$ for natural number $n$.

**Parameters**
- $z$: float or complex array_like

**Returns**
- $z$: float or complex
- The value(s) of gamma$(z)$

**Examples**

```python
>>> from scipy.special import gamma, factorial

>>> gamma([0, 0.5, 1, 5])
array([       inf, 1.7725, 1. , 24. ])

>>> z = 2.5 + 1j
>>> gamma(z)
(0.77476210455108352+0.70763120437959293j)
>>> gamma(z+1), z*gamma(z)  # Recurrence property
((1.2292740569981158+2.5438401155000658j),
 (1.2292740569981158+2.5438401155000658j))

>>> gamma(0.5)**2  # gamma(0.5) = sqrt(pi)
3.1415926535897927
```

Plot gamma$(x)$ for real $x$

```python
>>> x = np.linspace(-3.5, 5.5, 2251)
>>> y = gamma(x)

>>> import matplotlib.pyplot as plt
>>> plt.plot(x, y, 'b', alpha=0.6, label='gamma(x)')
```
```python
>>> k = np.arange(1, 7)
>>> plt.plot(k, factorial(k-1), 'k*', alpha=0.6,
...     label='(x-1)!, x = 1, 2, ...')
>>> plt.xlim(-3.5, 5.5)
>>> plt.ylim(-10, 25)
>>> plt.grid()
>>> plt.xlabel('x')
>>> plt.legend(loc='lower right')
>>> plt.show()
```

The code plots a curve of the factorial of `k-1` for `k` ranging from 1 to 7, with a label indicating that it represents `(x-1)!` for `x = 1, 2, ...`.

---

### scipy.special.gamma(n)

Logarithm of the absolute value of the Gamma function.

**Parameters**
- `x`: array-like

**Returns**
- `gamma(n)`: ndarray

Values on the real line at which to compute `gamma(n)`.

**See also:**
- `gammasgn` sign of the gamma function
- `loggamma` principal branch of the logarithm of the gamma function

**Notes**

When used in conjunction with `gammasgn`, this function is useful for working in logspace on the real axis without having to deal with complex numbers, via the relation $\exp(\text{gamma}(n)(x)) = \text{gammasgn}(x) \times \text{gamma}(x)$.

For complex-valued log-gamma, use `loggamma` instead of `gamma(n)`. 

---

### scipy.special.loggamma

Principal branch of the logarithm of the Gamma function.

Defined to be $\log(\Gamma(x))$ for $x > 0$ and extended to the complex plane by analytic continuation. The function has a single branch cut on the negative real axis.

New in version 0.18.0.

**Parameters**
- `z`: array-like
Values in the complex plain at which to compute \( \text{loggamma} \)

**out** : ndarray, optional
Output array for computed values of \( \text{loggamma} \)

**Returns**

- **loggamma** : ndarray
  Values of \( \text{loggamma} \) at \( z \).

**See also:**
- \( \text{gammaln} \) logarithm of the absolute value of the Gamma function
- \( \text{gammasgn} \) sign of the gamma function

**Notes**

It is not generally true that \( \log \Gamma(z) = \log(\Gamma(z)) \), though the real parts of the functions do agree. The benefit of not defining \( \text{loggamma} \) as \( \log(\Gamma(z)) \) is that the latter function has a complicated branch cut structure whereas \( \text{loggamma} \) is analytic except for on the negative real axis.

The identities

\[
\exp(\log \Gamma(z)) = \Gamma(z)
\]
\[
\log(\Gamma(z+1)) = \log(z) + \log(\Gamma(z))
\]

make \( \text{loggamma} \) useful for working in complex logspace. However, \( \text{loggamma} \) necessarily returns complex outputs for real inputs, so if you want to work only with real numbers use \( \text{gammaln} \). On the real line the two functions are related by \( \exp(\text{loggamma}(x)) = \text{gammasgn}(x) \cdot \exp(\text{gammaln}(x)) \), though in practice rounding errors will introduce small spurious imaginary components in \( \exp(\text{loggamma}(x)) \).

The implementation here is based on \([hare1997]\).

**References**

\([hare1997]\)

scipy.special.\( \text{gammasgn} \)(\( x \)) = <ufunc ‘gammasgn’>
Sign of the gamma function.

**See also:**
- \( \text{gammaln}, \text{loggamma} \)

scipy.special.\( \text{gammainc} \)(\( a, x \)) = <ufunc ‘gammainc’>
Regularized lower incomplete gamma function.

Defined as

\[
\frac{1}{\Gamma(a)} \int_0^x t^{a-1} e^{-t} dt
\]

for \( a > 0 \) and \( x \geq 0 \). The function satisfies the relation \( \text{gammainc}(a, x) + \text{gammaincc}(a, x) = 1 \) where \( \text{gammaincc} \) is the regularized upper incomplete gamma function.

**See also:**
- \( \text{gammaincc} \) regularized upper incomplete gamma function
- \( \text{gammaincinv} \) inverse to \( \text{gammainc} \) versus \( x \)
- \( \text{gammainccinv} \) inverse to \( \text{gammaincc} \) versus \( x \)

**Notes**

The implementation largely follows that of \([R470]\).
scipy.special.gammaincinv(a, y) = <ufunc ‘gammaincinv’>
Inverse to gammainc
Returns x such that gammainc(a, x) = y.

scipy.special.gammaincc(a, x) = <ufunc ‘gammaincc’>
Regularized upper incomplete gamma function.
Defined as
\[ \frac{1}{\Gamma(a)} \int_x^\infty t^{a-1}e^{-t}dt \]
for \( a > 0 \) and \( x \geq 0 \). The function satisfies the relation gammainc(a, x) + gammaincc(a, x) = 1
where gammainc is the regularized lower incomplete gamma function.

See also:
gammainc  regularized lower incomplete gamma function
gammaincinv  inverse to gammainc versus x
gammainccinv  inverse to gammaincc versus x

Notes
The implementation largely follows that of [R471].

References
[R471]

scipy.special.gammainccinv(a, y) = <ufunc ‘gammainccinv’>
Inverse to gammaincc
Returns x such that gammaincc(a, x) == y.

scipy.special.beta(a, b) = <ufunc ‘beta’>
Beta function.
\[ \text{beta}(a, b) = \gamma(a) \times \gamma(b) / \gamma(a+b) \]

scipy.special.betaln(a, b) = <ufunc ‘betaln’>
Natural logarithm of absolute value of beta function.
\[ \ln(\text{abs(beta}(a, b))) \]

scipy.special.betainc(a, b, x) = <ufunc ‘betainc’>
Incomplete beta integral.
Compute the incomplete beta integral of the arguments, evaluated from zero to x:
\[ \text{gamma}(a+b) / (\text{gamma}(a) \times \text{gamma}(b)) \times \text{integral} (t^(a-1) (1-t)^(b-1), t=0..x) \]

Notes
The incomplete beta is also sometimes defined without the terms in gamma, in which case the above definition is
the so-called regularized incomplete beta. Under this definition, you can get the incomplete beta by multiplying
the result of the scipy function by beta(a, b).
scipy.special.betaincinv \((a, b, y)\) = <ufunc ‘betaincinv’>
Inverse function to beta integral.
Compute \(x\) such that \(\text{betainc}(a, b, x) = y\).

scipy.special.psi \((z, \text{out=None})\) = <ufunc ‘psi’>
The digamma function.
The logarithmic derivative of the gamma function evaluated at \(z\).

Parameters
---
- \(z\) : array_like
  Real or complex argument.
- \(\text{out}\) : ndarray, optional
  Array for the computed values of \(\psi\).

Returns
---
- \(\text{digamma}\) : ndarray
  Computed values of \(\psi\).

Notes
For large values not close to the negative real axis \(\psi\) is computed using the asymptotic series (5.11.2) from [R562]. For small arguments not close to the negative real axis the recurrence relation (5.5.2) from [R562] is used until the argument is large enough to use the asymptotic series. For values close to the negative real axis the reflection formula (5.5.4) from [R562] is used first. Note that \(\psi\) has a family of zeros on the negative real axis which occur between the poles at nonpositive integers. Around the zeros the reflection formula suffers from cancellation and the implementation loses precision. The sole positive zero and the first negative zero, however, are handled separately by precomputing series expansions using [R563], so the function should maintain full accuracy around the origin.

scipy.special.rgamma \((z)\) = <ufunc ‘rgamma’>
Gamma function inverted

Returns \(1 / \Gamma(x)\)

scipy.special.polygamma \((n, x)\)
Polygamma function \(n\).
This is the \(n\)th derivative of the digamma (\(\psi\)) function.

Parameters
---
- \(n\) : array_like of int
  The order of the derivative of \(\psi\).
- \(x\) : array_like

Returns
---
- \(\text{polygamma}\) : ndarray
  Where to evaluate the polygamma function.
  The result.

Examples
---

```python
>>> from scipy import special
>>> x = [2, 3, 25.5]
>>> special.polygamma(1, x)
array([ 0.64493407, 0.39493407, 0.03999467])
>>> special.polygamma(0, x) == special.psi(x)
array([ True,  True,  True], dtype=bool)
```

scipy.special.multigammaln \((a, d)\)
Returns the log of multivariate gamma, also sometimes called the generalized gamma.

Parameters
---
a : ndarray
The multivariate gamma is computed for each item of \( a \).

\[ d : \text{int} \]

**Returns**

\[ \text{res} : \text{ndarray} \]

The dimension of the space of integration.

The values of the log multivariate gamma at the given points \( a \).

**Notes**

The formal definition of the multivariate gamma of dimension \( d \) for a real \( a \) is

\[
\Gamma_d(a) = \int_{A > 0} e^{-\text{tr}(A)} |A|^{a-(d+1)/2} \, dA
\]

with the condition \( a > (d-1)/2 \), and \( A > 0 \) being the set of all the positive definite matrices of dimension \( d \). Note that \( a \) is a scalar: the integrand only is multivariate, the argument is not (the function is defined over a subset of the real set).

This can be proven to be equal to the much friendlier equation

\[
\Gamma_d(a) = \pi^{d(d-1)/4} \prod_{i=1}^{d} \Gamma(a - (i - 1)/2).
\]

**References**

scipy.special.digamma \( z, \text{out=None} \) = <ufunc ‘psi’>

The digamma function.

The logarithmic derivative of the gamma function evaluated at \( z \).

**Parameters**

\[ z : \text{array_like} \]

Real or complex argument.

\[ \text{out} : \text{ndarray}, \text{optional} \]

**Returns**

\[ \text{digamma} : \text{ndarray} \]

Array for the computed values of \( \psi \).

Computed values of \( \psi \).

**Notes**

For large values not close to the negative real axis \( \psi \) is computed using the asymptotic series (5.11.2) from [R441]. For small arguments not close to the negative real axis the recurrence relation (5.5.2) from [R441] is used until the argument is large enough to use the asymptotic series. For values close to the negative real axis the reflection formula (5.5.4) from [R441] is used first. Note that \( \psi \) has a family of zeros on the negative real axis which occur between the poles at nonpositive integers. Around the zeros the reflection formula suffers from cancellation and the implementation loses precision. The sole positive zero and the first negative zero, however, are handled separately by precomputing series expansions using [R442], so the function should maintain full accuracy around the origin.

**References**

[R441], [R442]

scipy.special.poch \( z, m \) = <ufunc ‘poch’>

Rising factorial \((z)_m\)

The Pochhammer symbol (rising factorial), is defined as

\[
(z)_m = \frac{\Gamma(z + m)}{\Gamma(z)}
\]
For positive integer \( m \) it reads

\[
(z)_m = z(z+1)...(z+m-1)
\]

**Parameters**
- \( z : \text{array_like} \) (int or float)
- \( m : \text{array_like} \) (int or float)

**Returns**
- \( \text{poch} : \text{ndarray} \) (int or float)

The value of the function.

### Error Function and Fresnel Integrals

- \( \text{erf}(z) \) Returns the error function of complex argument.
- \( \text{erfc}(x) \) Complementary error function, \( 1 - \text{erf}(x) \).
- \( \text{erfcx}(x) \) Scaled complementary error function, \( \exp(x**2) \ast \text{erfc}(x) \).
- \( \text{erfi}(z) \) Imaginary error function, \( -i \ast \text{erf}(i \ast z) \).
- \( \text{erfinv}(y) \) Inverse function for \( \text{erf} \).
- \( \text{erfcinv}(y) \) Inverse function for \( \text{erfc} \).
- \( \text{wofz}(z) \) Faddeeva function
- \( \text{dawsn}(x) \) Dawson’s integral.
- \( \text{fresnel}(z) \) Fresnel sin and cos integrals
- \( \text{fresnel_zeros}(nt) \) Compute \( nt \) complex zeros of sine and cosine Fresnel integrals \( S(z) \) and \( C(z) \).
- \( \text{modfresnelp}(x) \) Modified Fresnel positive integrals
- \( \text{modfresnelm}(x) \) Modified Fresnel negative integrals

#### scipy.special.\( \text{erf}(z) \) = <ufunc ‘erf’>

Returns the error function of complex argument.

It is defined as \( 2/sqrt(pi) \ast \text{integral}(exp(-t**2), t=0..z) \).

**Parameters**
- \( x : \text{ndarray} \)

**Returns**
- \( \text{res} : \text{ndarray} \)

Input array.

The values of the error function at the given points \( x \).

See also:

\( \text{erfc,erfinv,erfcinv,wofz,erfcx,erfi} \)

**Notes**

The cumulative of the unit normal distribution is given by \( \Phi(z) = 1/2[1 + \text{erf}(z/sqrt(2))] \).

**References**

[R456], [R457], [R458]

**Examples**

```python
>>> from scipy import special
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-3, 3)
>>> plt.plot(x, special.erf(x))
```
scipy.special.erfc(x) = <ufunc 'erfc'>
Complementary error function, $1 - \text{erf}(x)$.

See also:
erf, erfi, erfcx, dawsn, wofz

References
[R460]

Examples

```python
>>> from scipy import special
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-3, 3)
>>> plt.plot(x, special.erfc(x))
>>> plt.xlabel('$x$')
>>> plt.ylabel('$\text{erfc}(x)$')
>>> plt.show()
```
scipy.special.erfcx(x) = <ufunc 'erfcx'>

Scaled complementary error function, \( \exp(x^2) \ast \text{erfc}(x) \).

See also:

erf, erfc, erfi, dawsn, wofz

Notes

New in version 0.12.0.

References

[R461]

Examples

```python
>>> from scipy import special
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-3, 3)
>>> plt.plot(x, special.erfcx(x))
>>> plt.xlabel('$x$')
>>> plt.ylabel('$erfcx(x)$')
>>> plt.show()
```
scipy.special.erfi(z) = <ufunc ‘erfi’>
Imaginary error function, $-i \text{erf}(iz)$.

See also:
erf, erfc, erfcx, dawsn, wofz

Notes
New in version 0.12.0.

References
[R462]

Examples

```python
>>> from scipy import special
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-3, 3)
>>> plt.plot(x, special.erfi(x))
>>> plt.xlabel('$x$')
>>> plt.ylabel('$\text{erfi}(x)$')
>>> plt.show()
```
scipy.special.erfinv(y)
Inverse function for erf.

scipy.special.erfcinv(y)
Inverse function for erfc.

scipy.special.wofz(z) = <ufunc ‘wofz’>
Faddeeva function

Returns the value of the Faddeeva function for complex argument:

\[ \exp(-z^2) \times \text{erfc}(-i\times z) \]

See also:

dawsn, erf, erfc, erfcx, erfi

References

[R587]

Examples

```python
>>> from scipy import special
>>> import matplotlib.pyplot as plt

>>> x = np.linspace(-3, 3)
>>> z = special.wofz(x)

>>> plt.plot(x, z.real, label='wofz(x).real')
>>> plt.plot(x, z.imag, label='wofz(x).imag')
>>> plt.xlabel('$x$')
>>> plt.legend(framealpha=1, shadow=True)
>>> plt.grid(alpha=0.25)
>>> plt.show()
```
scipy.special.dawsn(x) = <ufunc ‘dawsn’>

Dawson’s integral.

Computes:

\[ \exp(-x^2) \times \text{integral}(\exp(t^2), t=0..x). \]

See also:

wofz, erf, erfc, erfcx, erfi

References

[R440]

Examples

```python
>>> from scipy import special
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-15, 15, num=1000)
>>> plt.plot(x, special.dawsn(x))
>>> plt.xlabel('$x$')
>>> plt.ylabel('$dawsn(x)$')
>>> plt.show()
```
scipy.special.fresnel(z) = <ufunc ‘fresnel’>
Fresnel sin and cos integrals

Defined as:

\[
\begin{align*}
ssa &= \int_{0}^{z} \sin\left(\frac{\pi}{2} t^2\right) \, dt \\
csa &= \int_{0}^{z} \cos\left(\frac{\pi}{2} t^2\right) \, dt
\end{align*}
\]

**Parameters**
- *z*: float or complex array_like

**Returns**
- *ssa*, *csa*: Argument
  - Fresnel sin and cos integral values

scipy.special.fresnel_zeros(nt)
Compute *nt* complex zeros of sine and cosine Fresnel integrals *S(z)* and *C(z)*.

**References**
[R467]

scipy.special.modfresnelp(x) = <ufunc ‘modfresnelp’>
Modified Fresnel positive integrals

**Returns**
- *fp*, *kp*
  - Integral \(F_+(x) = \int_{x}^{\infty} \exp(1j*t*t) \, dt\)
  - Integral \(K_+(x) = 1/\sqrt{\pi} \exp(-1j*(x^2+\pi/4))*fp\)

scipy.special.modfresnelm(x) = <ufunc ‘modfresnelm’>
Modified Fresnel negative integrals

**Returns**
- *fm*, *km*
  - Integral \(F_-(x) = \int_{x}^{\infty} \exp(-1j*t*t) \, dt\)
  - Integral \(K_-(x) = 1/\sqrt{\pi} \exp(1j*(x^2+\pi/4))*fp\)

These are not universal functions:

### Legendre Functions

**lpmv(m, v, x)**
Associated Legendre function of integer order and real degree.

**sph_harm(m, n, theta, phi)**
Compute spherical harmonics.

```python
scipy.special.lpmv(m, v, x) = <ufunc ‘lpmv’>
```
Associated Legendre function of integer order and real degree.

Defined as

\[ P_{m}^{v}(x) = (-1)^{m}(1 - x^{2})^{m/2} \frac{d^{m}}{dx^{m}} P_{v}(x) \]

where

\[ P_{v} = \sum_{k=0}^{\infty} \frac{(-v)_{k}(v + 1)_{k}}{(k!)^{2}} \left( \frac{1 - x}{2} \right)^{k} \]

is the Legendre function of the first kind. Here \((\cdot)_{k}\) is the Pochhammer symbol; see `poch`.

**Parameters**

- **m** : array_like
  Order (int or float). If passed a float not equal to an integer the function returns NaN.
- **v** : array_like
  Degree (float).
- **x** : array_like
  Argument (float). Must have \(|x| \leq 1\).

**Returns**

- **pmv** : ndarray
  Value of the associated Legendre function.
See also:

* lpmn: Compute the associated Legendre function for all orders 0, ..., m and degrees 0, ..., n.
* clpmn: Compute the associated Legendre function at complex arguments.

**Notes**

Note that this implementation includes the Condon-Shortley phase.

**References**

[538]

scipy.special.sph_harm(m, n, theta, phi) = <ufunc ‘sph_harm’>

Compute spherical harmonics.

The spherical harmonics are defined as

$$Y_n^m(\theta, \phi) = \sqrt{\frac{2n+1}{4\pi} \frac{(n-m)!}{(n+m)!}} e^{im\theta} P_n^m(\cos(\phi))$$

where $P_n^m$ are the associated Legendre functions; see lpmv.

**Parameters**

- `m` : array_like
  - Order of the harmonic (int); must have $|m| \leq n$.
- `n` : array_like
  - Degree of the harmonic (int); must have $n \geq 0$. This is often denoted by l (lower case L) in descriptions of spherical harmonics.
- `theta` : array_like
  - Azimuthal (longitudinal) coordinate; must be in $[0, 2\pi]$.
- `phi` : array_like
  - Polar (colatitudinal) coordinate; must be in $[0, \pi]$.

**Returns**

- `y_mn` : complex float
  - The harmonic $Y_n^m$ sampled at `theta` and `phi`.

**Notes**

There are different conventions for the meanings of the input arguments `theta` and `phi`. In SciPy `theta` is the azimuthal angle and `phi` is the polar angle. It is common to see the opposite convention, that is, `theta` as the polar angle and `phi` as the azimuthal angle.

Note that SciPy’s spherical harmonics include the Condon-Shortley phase [R575] because it is part of lpmv.

With SciPy’s conventions, the first several spherical harmonics are

$$Y_0^0(\theta, \phi) = \frac{1}{2} \sqrt{\frac{1}{\pi}}$$
$$Y_1^{-1}(\theta, \phi) = \frac{1}{2} \sqrt{\frac{3}{2\pi}} e^{-i\theta} \sin(\phi)$$
$$Y_1^0(\theta, \phi) = \frac{1}{2} \sqrt{\frac{3}{\pi}} \cos(\phi)$$
$$Y_1^1(\theta, \phi) = \frac{1}{2} \sqrt{\frac{3}{2\pi}} e^{i\theta} \sin(\phi).$$

**References**

[R574], [R575]

These are not universal functions:
clpmn\( (m, n, z[, type]) \)

Associated Legendre function of the first kind for complex arguments.

lpn\( (n, z) \)

Legendre function of the first kind.

lqn\( (n, z) \)

Legendre function of the second kind.

lpmn\( (m, n, z) \)

Sequence of associated Legendre functions of the first kind.

lqmn\( (m, n, z) \)

Sequence of associated Legendre functions of the second kind.

scipy.special.clpmn\( m, n, z[, type=3] \)

Associated Legendre function of the first kind for complex arguments.

Computes the associated Legendre function of the first kind of order \( m \) and degree \( n \), \( P_m^n(z) = P_m^n(z) \), and its derivative, \( P_m^n(z') \). Returns two arrays of size \((m+1, n+1)\) containing \( P_m^n(z) \) and \( P_m^n(z') \) for all orders from 0..\( m \) and degrees from 0..\( n \).

**Parameters**

- \( m \) : int
  - \(|m| \leq n\); the order of the Legendre function.
- \( n \) : int
  - where \( n \geq 0 \); the degree of the Legendre function. Often called \( l \) (lower case L) in descriptions of the associated Legendre function.
- \( z \) : float or complex
  - Input value.
- \( type \) : int, optional
  - takes values 2 or 3:
  - 2: cut on the real axis \(|x| > 1\)
  - 3: cut on the real axis \([-1 < x < 1\) (default)]

**Returns**

- \( P_m^n(z) \) : \((m+1, n+1)\) array
  - Values for all orders 0..\( m \) and degrees 0..\( n \).
- \( P_m^n(z') \) : \((m+1, n+1)\) array
  - Derivatives for all orders 0..\( m \) and degrees 0..\( n \).

**See also:**

- lpmn
  - associated Legendre functions of the first kind for real \( z \)

**Notes**

By default, i.e. for \( type=3 \), phase conventions are chosen according to \([R437]\) such that the function is analytic. The cut lies on the interval \((-1, 1)\). Approaching the cut from above or below in general yields a phase factor with respect to Ferrer’s function of the first kind (cf. \( lpmn \)).

For \( type=2 \) a cut at \(|x| > 1\) is chosen. Approaching the real values on the interval \((-1, 1)\) in the complex plane yields Ferrer’s function of the first kind.

**References**

- \([R437]\), \([R438]\)

scipy.special.lpn\( n, z \)

Legendre function of the first kind.

Compute sequence of Legendre functions of the first kind (polynomials), \( P_n(z) \) and derivatives for all degrees from 0 to \( n \) (inclusive).

See also special.legendre for polynomial class.
**References**

[R539]

scipy.special.lqn(n, z)

Legendre function of the second kind.

Compute sequence of Legendre functions of the second kind, \( Q_n(z) \) and derivatives for all degrees from 0 to \( n \) (inclusive).

**References**

[R541]

scipy.special.lpmn(m, n, z)

Sequence of associated Legendre functions of the first kind.

Computes the associated Legendre function of the first kind of order \( m \) and degree \( n \), \( P_{mn}(z) = P^m_n(z) \), and its derivative, \( P_{mn}'(z) \). Returns two arrays of size \((m+1, n+1)\) containing \( P_{mn}(z) \) and \( P_{mn}'(z) \) for all orders from 0 to \( m \) and degrees from 0 to \( n \).

This function takes a real argument \( z \). For complex arguments \( z \) use clpmn instead.

**Parameters**

- **m**: int
  
  \(|m| \leq n\); the order of the Legendre function.

- **n**: int
  
  \(n \geq 0\); the degree of the Legendre function. Often called \( l \) (lower case L) in descriptions of the associated Legendre function.

- **z**: float

**Returns**

- **Pmn_z**: \((m+1, n+1)\) array
  
  Values for all orders 0 to \( m \) and degrees 0 to \( n \).

- **Pmn_d_z**: \((m+1, n+1)\) array
  
  Derivatives for all orders 0 to \( m \) and degrees 0 to \( n \).

See also:

cplmn  
associated Legendre functions of the first kind for complex \( z \)

**Notes**

In the interval (-1, 1), Ferrer’s function of the first kind is returned. The phase convention used for the intervals \((1, \infty)\) and \((-\infty, -1)\) is such that the result is always real.

**References**

[R536], [R537]

scipy.special.lqmn(m, n, z)

Sequence of associated Legendre functions of the second kind.

Computes the associated Legendre function of the second kind of order \( m \) and degree \( n \), \( Q_{mn}(z) = Q^m_n(z) \), and its derivative, \( Q_{mn}'(z) \). Returns two arrays of size \((m+1, n+1)\) containing \( Q_{mn}(z) \) and \( Q_{mn}'(z) \) for all orders from 0 to \( m \) and degrees from 0 to \( n \).

**Parameters**

- **m**: int
  
  \(|m| \leq n\); the order of the Legendre function.

- **n**: int
  
  \(n \geq 0\); the degree of the Legendre function. Often called \( l \) (lower case L) in descriptions of the associated Legendre function.

- **z**: complex

**Returns**

- **Qmn_z**: \((m+1, n+1)\) array
  
  Input value.
Values for all orders 0..m and degrees 0..n

\[ Q_{mn_d_z} : (m+1, n+1) \text{ array} \]

Derivatives for all orders 0..m and degrees 0..n

**References**

[R540]

**Ellipsoidal Harmonics**

\[
\text{ellip\_harm}(h2, k2, n, p, s[, signm, signn]) \quad \text{Ellipsoidal harmonic functions } E^p_n(s)
\]

\[
\text{ellip\_harm}_2(h2, k2, n, p, s) \quad \text{Ellipsoidal harmonic functions } F^p_n(s)
\]

\[
\text{ellip\_normal}(h2, k2, n, p) \quad \text{Ellipsoidal harmonic normalization constants } \gamma^p_n
\]

scipy.special.ellip_harm(h2, k2, n, p, s[, signm, signn])  
Ellipsoidal harmonic functions \( E^p_n(s) \)

These are also known as Lame functions of the first kind, and are solutions to the Lame equation:

\[(s^2 - h^2)(s^2 - k^2)E''(s) + s(2s^2 - h^2 - k^2)E'(s) + (a - qs^2)E(s) = 0\]

where \( q = (n + 1)n \) and \( a \) is the eigenvalue (not returned) corresponding to the solutions.

**Parameters**

- \( h2 \) : float  
  \( h^2 \)
- \( k2 \) : float  
  \( k^2 \); should be larger than \( h^2 \)
- \( n \) : int  
  Degree
- \( s \) : float  
  Coordinate
- \( p \) : int  
  Order, can range between \([1,2n+1]\)
- \( \text{signm} \) : \([1,-1]\), optional  
  Sign of prefactor of functions. Can be +/-1. See Notes.
- \( \text{signn} \) : \([1,-1]\), optional  
  Sign of prefactor of functions. Can be +/-1. See Notes.

**Returns**

- \( E \) : float  
  Sign of prefactor of functions. Can be +/-1. See Notes.
  the harmonic \( E^p_n(s) \)

**See also:**

ellip_harm_2, ellip_normal

**Notes**

The geometric interpretation of the ellipsoidal functions is explained in [R444], [R445], [R446]. The \( \text{signm} \) and \( \text{signn} \) arguments control the sign of prefactors for functions according to their type:

<table>
<thead>
<tr>
<th>( K )</th>
<th>( L )</th>
<th>( M )</th>
<th>( N )</th>
</tr>
</thead>
<tbody>
<tr>
<td>+1</td>
<td>signm</td>
<td>signn</td>
<td>signm*signn</td>
</tr>
</tbody>
</table>

New in version 0.15.0.
References

[R443], [R444], [R445], [R446]

Examples

```python
>>> from scipy.special import ellip_harm
>>> w = ellip_harm(5,8,1,1,2.5)
>>> w
2.5
```

Check that the functions indeed are solutions to the Lame equation:

```python
>>> from scipy.interpolate import UnivariateSpline
>>> def eigenvalue(f, df, ddf):
...     r = ((s**2 - h**2)*(s**2 - k**2)*ddf + s*(2*s**2 - h**2 - k**2)*df - n*(n+1)*s**2*f)/f
...     return -r.mean(), r.std()
...     s = np.linspace(0.1, 10, 200)
>>> k, h, n, p = 8.0, 2.2, 3, 2
>>> E = ellip_harm(h**2, k**2, n, p, s)
>>> E_spl = UnivariateSpline(s, E)
>>> a, a_err = eigenvalue(E_spl(s), E_spl(s,1), E_spl(s,2))
>>> a, a_err
(583.44366156701483, 6.4580890640310646e-11)
```

`scipy.special.ellip_harm_2(h2, k2, n, p, s)`

Ellipsoidal harmonic functions $F^p_n(s)$

These are also known as Lame functions of the second kind, and are solutions to the Lame equation:

$$(s^2 - h^2)(s^2 - k^2)F''(s) + s(2s^2 - h^2 - k^2)F'(s) + (a - qs^2)F(s) = 0$$

where $q = (n + 1)n$ and $a$ is the eigenvalue (not returned) corresponding to the solutions.

**Parameters**

- `h2`: float
  - $h^2$
- `k2`: float
  - $k^2$; should be larger than $h^2$
- `n`: int
  - Degree.
- `p`: int
  - Order, can range between [1,2n+1].
- `s`: float
  - Coordinate

**Returns**

- `F`: float
  - The harmonic $F^p_n(s)$

See also:

`ellip_harm`, `ellip_normal`

**Notes**

Lame functions of the second kind are related to the functions of the first kind:

$$F^p_n(s) = (2n + 1)E^p_n(s) \int_0^{1/s} \frac{du}{(E^p_n(1/u))^2 \sqrt{(1 - u^2k^2)(1 - u^2h^2)}}$$

New in version 0.15.0.
Examples

```python
>>> from scipy.special import ellip_harm_2
>>> w = ellip_harm_2(5, 8, 2, 1, 10)
>>> w
0.00108056853382
```

`scipy.special.ellip_normal(h2, k2, n, p)`
Ellipsoidal harmonic normalization constants gamma^p_n

The normalization constant is defined as

\[
\gamma_n^p = 8 \int_0^h dx \int_h^k dy \frac{(y^2 - x^2)(E_p^n(y)E_p^n(x))^2}{\sqrt{(k^2 - y^2)(y^2 - h^2)(h^2 - x^2)(k^2 - x^2)}}
\]

**Parameters**

- `h2` : float
  \(h^2\)
- `k2` : float
  \(k^2\); should be larger than \(h^2\)
- `n` : int
  Degree.
- `p` : int
  Order, can range between \([1, 2n+1]\).

**Returns**

- `gamma` : float
  The normalization constant \(\gamma_n^p\)

**See also:**

`ellip_harm`, `ellip_harm_2`

**Notes**

New in version 0.15.0.

Examples

```python
>>> from scipy.special import ellip_normal
>>> w = ellip_normal(5, 8, 3, 7)
>>> w
1723.38796997
```

Orthogonal polynomials

The following functions evaluate values of orthogonal polynomials:

- `assoc_laguerre(x, n[, k])`
  Compute the generalized (associated) Laguerre polynomial of degree \(n\) and order \(k\).
- `eval_legendre(n, x[, out])`
  Evaluate Legendre polynomial at a point.
- `eval_chebyt(n, x[, out])`
  Evaluate Chebyshev polynomial of the first kind at a point.
- `eval_chebyu(n, x[, out])`
  Evaluate Chebyshev polynomial of the second kind at a point.
- `eval_chebyc(n, x[, out])`
  Evaluate Chebyshev polynomial of the first kind on \([-2, 2]\] at a point.
- `eval_chebys(n, x[, out])`
  Evaluate Chebyshev polynomial of the second kind on \([-2, 2]\] at a point.
- `eval_jacobi(n, alpha, beta, x[, out])`
  Evaluate Jacobi polynomial at a point.

**scipy.special.assoc_laguerre(x, n, k=0.0)**

Compute the generalized (associated) Laguerre polynomial of degree n and order k.

The polynomial \( L_n^{(k)}(x) \) is orthogonal over \([0, \infty)\), with weighting function \( \exp(-x) \times x^k \) with \( k > -1 \).

**Notes**

`assoc_laguerre` is a simple wrapper around `eval_genlaguerre`, with reversed argument order \((x, n, k=0.0) \rightarrow (n, k, x)\).

**scipy.special.eval_legendre(n, x, out=None)** = `<ufunc ‘eval_legendre’>`

Evaluate Legendre polynomial at a point.

The Legendre polynomials can be defined via the Gauss hypergeometric function \( {}_2F_1 \) as

\[
P_n(x) = {}_2F_1(-n, n + 1; 1; (1 - x)/2).
\]

When \( n \) is an integer the result is a polynomial of degree \( n \).

**Parameters**

- `n`: array_like
  Degree of the polynomial. If not an integer, the result is determined via the relation to the Gauss hypergeometric function.

- `x`: array_like
  Points at which to evaluate the Legendre polynomial

**Returns**

- `P`: ndarray
  Values of the Legendre polynomial

**See also:**

- `roots_legendre`
  roots and quadrature weights of Legendre polynomials
- `legendre`
  Legendre polynomial object
- `hyp2f1`
  Gauss hypergeometric function
- `numpy.polynomial.legendre.Legendre`
  Legendre series

**scipy.special.eval_chebyt(n, x, out=None)** = `<ufunc ‘eval_chebyt’>`

Evaluate Chebyshev polynomial of the first kind at a point.

The Chebyshev polynomials of the first kind can be defined via the Gauss hypergeometric function \( {}_2F_1 \) as

\[
T_n(x) = {}_2F_1(n, -n; 1/2; (1 - x)/2).
\]

When \( n \) is an integer the result is a polynomial of degree \( n \).
**Parameters**  
\( n \) : array_like  
Degree of the polynomial. If not an integer, the result is determined via the relation to the Gauss hypergeometric function.

\( x \) : array_like  
Points at which to evaluate the Chebyshev polynomial

**Returns**  
\( T \) : ndarray  
Values of the Chebyshev polynomial

**See also:**
- `roots_chebyt`
  roots and quadrature weights of Chebyshev polynomials of the first kind
- `chebyu`
  Chebyshev polynomial object
- `eval_chebyu`
  evaluate Chebyshev polynomials of the second kind
- `hyp2f1`
  Gauss hypergeometric function
- `numpy.polynomial.chebyshev.Chebyshev`
  Chebyshev series

**Notes**

This routine is numerically stable for \( x \) in \([-1, 1]\) at least up to order 10000.

\[
\text{scipy.special.eval_chebyu}(n, x, out=None) = <ufunc 'eval_chebyu'>
\]

Evaluate Chebyshev polynomial of the second kind at a point.

The Chebyshev polynomials of the second kind can be defined via the Gauss hypergeometric function \( _2F_1 \) as

\[
U_n(x) = (n + 1)_2F_1(-n, n + 2; 3/2; (1 - x)/2).
\]

When \( n \) is an integer the result is a polynomial of degree \( n \).

**Parameters**  
\( n \) : array_like  
Degree of the polynomial. If not an integer, the result is determined via the relation to \( \text{eval_chebyt} \).

\( x \) : array_like  
Points at which to evaluate the Chebyshev polynomial

**Returns**  
\( U \) : ndarray  
Values of the Chebyshev polynomial

**See also:**
- `roots_chebyu`
  roots and quadrature weights of Chebyshev polynomials of the second kind
- `chebyu`
  Chebyshev polynomial object
- `eval_chebyt`
  evaluate Chebyshev polynomials of the first kind
- `hyp2f1`
  Gauss hypergeometric function

\[
\text{scipy.special.eval_chebyc}(n, x, out=None) = <ufunc 'eval_chebyc'>
\]

Evaluate Chebyshev polynomial of the first kind on \([-2, 2]\) at a point.

These polynomials are defined as

\[
S_n(x) = T_n(x/2)
\]

where \( T_n \) is a Chebyshev polynomial of the first kind.

**Parameters**  
\( n \) : array_like  
Degree of the polynomial. If not an integer, the result is determined via the relation to \( \text{eval_chebyt} \).
x : array_like

Points at which to evaluate the Chebyshev polynomial

Returns

C : ndarray

Values of the Chebyshev polynomial

See also:

roots_chebyc
roots and quadrature weights of Chebyshev polynomials of the first kind on [-2, 2]

chebyc
Chebyshev polynomial object
numpy.polynomial.chebyshev.Chebyshev
Chebyshev series
eval_chebyt
evaluate Chebyshev polynomials of the first kind

scipy.special.eval_chebys(n, x, out=None) = <ufunc 'eval_chebys'>
Evaluate Chebyshev polynomial of the second kind on [-2, 2] at a point.

These polynomials are defined as

\[ S_n(x) = U_n(x/2) \]

where \( U_n \) is a Chebyshev polynomial of the second kind.

Parameters

n : array_like
Degree of the polynomial. If not an integer, the result is determined via the relation to \( \text{eval}_\text{chebyu} \).

x : array_like
Points at which to evaluate the Chebyshev polynomial

Returns

S : ndarray
Values of the Chebyshev polynomial

See also:

roots_chebys
roots and quadrature weights of Chebyshev polynomials of the second kind on [-2, 2]

chebys
Chebyshev polynomial object
eval_chebyu
evaluate Chebyshev polynomials of the second kind

scipy.special.eval_jacobi(n, alpha, beta, x, out=None) = <ufunc 'eval_jacobi'>
Evaluate Jacobi polynomial at a point.

The Jacobi polynomials can be defined via the Gauss hypergeometric function \( _2F_1 \) as

\[ P_n^{(\alpha, \beta)}(x) = \frac{(\alpha + 1)_n}{\Gamma(n + 1)} 2F_1(-n, 1 + \alpha + \beta + n; \alpha + 1; (1 - x)/2) \]

where \((\cdot)_n\) is the Pochhammer symbol; see \( \text{poch} \). When \( n \) is an integer the result is a polynomial of degree \( n \).

Parameters

n : array_like
Degree of the polynomial. If not an integer the result is determined via the relation to the Gauss hypergeometric function.

alpha : array_like
Parameter

beta : array_like
Parameter

x : array_like
Points at which to evaluate the polynomial

Returns

P : ndarray
Values of the Jacobi polynomial
Evaluate Laguerre polynomial at a point.

The Laguerre polynomials can be defined via the confluent hypergeometric function $_1F_1$ as

$$L_n(x) = _1F_1(-n, 1, x).$$

When $n$ is an integer the result is a polynomial of degree $n$.

**Parameters**
- `n`: array_like
  Degree of the polynomial. If not an integer the result is determined via the relation to the confluent hypergeometric function.
- `x`: array_like
  Points at which to evaluate the Laguerre polynomial

**Returns**
- `L`: ndarray
  Values of the Laguerre polynomial

See also:
- `roots_laguerre`
  roots and quadrature weights of Laguerre polynomials
- `laguerre`
  Laguerre polynomial object
- `numpy.polynomial.laguerre.Laguerre`
  Laguerre series

Evaluate generalized Laguerre polynomial at a point.

The generalized Laguerre polynomials can be defined via the confluent hypergeometric function $_1F_1$ as

$$L_n^{(\alpha)}(x) = \binom{n + \alpha}{n} _1F_1(-n, \alpha + 1, x).$$

When $n$ is an integer the result is a polynomial of degree $n$. The Laguerre polynomials are the special case where $\alpha = 0$.

**Parameters**
- `n`: array_like
  Degree of the polynomial. If not an integer the result is determined via the relation to the confluent hypergeometric function.
- `alpha`: array_like
  Parameter; must have $\alpha > -1$
- `x`: array_like
  Points at which to evaluate the generalized Laguerre polynomial

**Returns**
- `L`: ndarray
  Values of the generalized Laguerre polynomial

See also:
- `roots_genlaguerre`
  roots and quadrature weights of generalized Laguerre polynomials
- `genlaguerre`
  generalized Laguerre polynomial object
hyp1f1  confluent hypergeometric function

eval_laguerre  evaluate Laguerre polynomials

scipy.special.eval_hermite(n, x, out=None) = <ufunc ‘eval_hermite’>
Evaluate physicist’s Hermite polynomial at a point.
Defined by

\[ H_n(x) = (-1)^n e^{x^2} \frac{d^n}{dx^n} e^{-x^2}; \]

\( H_n \) is a polynomial of degree \( n \).

Parameters:
- \( n \) : array_like
  Degree of the polynomial
- \( x \) : array_like
  Points at which to evaluate the Hermite polynomial

Returns:
- \( H \) : ndarray
  Values of the Hermite polynomial

See also:
- roots_hermite  roots and quadrature weights of physicist’s Hermite polynomials
- hermite  physicist’s Hermite polynomial object
  numpy.polynomial.hermite.Hermite  Physicist’s Hermite series
- eval_hermitenorm  evaluate Probabilist’s Hermite polynomials

scipy.special.eval_hermitenorm(n, x, out=None) = <ufunc ‘eval_hermitenorm’>
Evaluate probabilist’s (normalized) Hermite polynomial at a point.
Defined by

\[ H_e_n(x) = (-1)^n e^{x^2/2} \frac{d^n}{dx^n} e^{-x^2/2}; \]

\( H_e_n \) is a polynomial of degree \( n \).

Parameters:
- \( n \) : array_like
  Degree of the polynomial
- \( x \) : array_like
  Points at which to evaluate the Hermite polynomial

Returns:
- \( H_e \) : ndarray
  Values of the Hermite polynomial

See also:
- roots_hermitenorm  roots and quadrature weights of probabilist’s Hermite polynomials
- hermitenorm  probabilist’s Hermite polynomial object
  numpy.polynomial.hermite_e.HermiteE  Probabilist’s Hermite series
- eval_hermite  evaluate physicist’s Hermite polynomials

scipy.special.eval_gegenbauer(n, alpha, x, out=None) = <ufunc ‘eval_gegenbauer’>
Evaluate Gegenbauer polynomial at a point.
The Gegenbauer polynomials can be defined via the Gauss hypergeometric function \( {}_2F_1 \) as

\[
C_n^{(\alpha)} = \frac{(2\alpha)_n}{\Gamma(n + 1)} {}_2F_1(-n, 2\alpha + n; \alpha + 1/2; (1 - z)/2).
\]

When \( n \) is an integer the result is a polynomial of degree \( n \).

**Parameters**
- **n**: array_like
  Degree of the polynomial. If not an integer, the result is determined via the relation to the Gauss hypergeometric function.
- **alpha**: array_like
  Parameter
- **x**: array_like

**Returns**
- **C**: ndarray
  Points at which to evaluate the Gegenbauer polynomial
  Values of the Gegenbauer polynomial

**See also:**
- `roots_gegenbauer`
- `roots and quadrature weights of Gegenbauer polynomials`
- `gegenbauer`
- `Gegenbauer polynomial object`
- `hyp2f1`
- `Gauss hypergeometric function`

**scipy.special.eval_sh_legendre**

\((n, x, out=None) = \text{<ufunc \textit{eval\_sh\_legendre}>}\)

Evaluate shifted Legendre polynomial at a point.

These polynomials are defined as

\[
P_n^*(x) = P_n(2x - 1)
\]

where \( P_n \) is a Legendre polynomial.

**Parameters**
- **n**: array_like
  Degree of the polynomial. If not an integer, the value is determined via the relation to `eval_legendre`.
- **x**: array_like

**Returns**
- **P**: ndarray
  Points at which to evaluate the shifted Legendre polynomial
  Values of the shifted Legendre polynomial

**See also:**
- `roots_sh_legendre`
- `roots and quadrature weights of shifted Legendre polynomials`
- `sh_legendre`
- `shifted Legendre polynomial object`
- `eval_legendre`
- `evaluate Legendre polynomials`
- `numpy.polynomial.legendre.Legendre`
- `Legendre series`

**scipy.special.eval_sh_chebyt**

\((n, x, out=None) = \text{<ufunc \textit{eval\_sh\_chebyt}>}\)

Evaluate shifted Chebyshev polynomial of the first kind at a point.

These polynomials are defined as

\[
T_n^*(x) = T_n(2x - 1)
\]

where \( T_n \) is a Chebyshev polynomial of the first kind.

**Parameters**
- **n**: array_like
Degree of the polynomial. If not an integer, the result is determined via the relation to :func:`eval_chebyt`.

.. _chebyt:

.. code-block::

   x : array_like

Returns

.. _chebyt:

.. code-block::

   T : ndarray

Points at which to evaluate the shifted Chebyshev polynomial

Values of the shifted Chebyshev polynomial

See also:

- :func:`roots_sh_cheby`
  - roots and quadrature weights of shifted Chebyshev polynomials of the first kind
- :func:`sh_cheby`
  - shifted Chebyshev polynomial object
- :func:`eval_chebyt`
  - evaluate Chebyshev polynomials of the first kind
- :func:`numpy.polynomial.chebyshev.Chebyshev`
  - Chebyshev series

.. _chebyu:

.. code-block::

   scipy.special.eval_sh_chebyu(n, x, out=None) = <ufunc 'eval_sh_chebyu'>

Evaluate shifted Chebyshev polynomial of the second kind at a point.

These polynomials are defined as

\[ U_n^*(x) = U_n(2x - 1) \]

where \( U_n \) is a Chebyshev polynomial of the first kind.

Parameters

- n : array_like
  - Degree of the polynomial. If not an integer, the result is determined via the relation to :func:`eval_chebyu`.
- x : array_like
  - Points at which to evaluate the shifted Chebyshev polynomial

Returns

- U : ndarray
  - Values of the shifted Chebyshev polynomial

See also:

- :func:`roots_sh_chebyu`
  - roots and quadrature weights of shifted Chebychev polynomials of the second kind
- :func:`sh_chebyu`
  - shifted Chebyshev polynomial object
- :func:`eval_chebyu`
  - evaluate Chebyshev polynomials of the second kind

.. _chebyu:

.. code-block::

   scipy.special.eval_sh_jacobi(n, p, q, x, out=None) = <ufunc 'eval_sh_jacobi'>

Evaluate shifted Jacobi polynomial at a point.

Defined by

\[
G_n^{(p,q)}(x) = \binom{2n + p - 1}{n}^{-1} P_n^{(p-q,q-1)}(2x - 1),
\]

where \( P_n^{(\cdot,\cdot)} \) is the \( n \)-th Jacobi polynomial.

Parameters

- n : int
  - Degree of the polynomial. If not an integer, the result is determined via the relation to :func:`binom` and :func:`eval_jacobi`.
- p : float
  - Parameter
- q : float
  - Parameter

Returns

- G : ndarray
  - Values of the shifted Jacobi polynomial.

**scipy.special.roots_legendre** *(n, mu=False)*

Gauss-Legendre quadrature.

Computes the sample points and weights for Gauss-Legendre quadrature. The sample points are the roots of the n-th degree Legendre polynomial $P_n(x)$. These sample points and weights correctly integrate polynomials of degree $2n-1$ or less over the interval $[-1, 1]$ with weight function $f(x) = 1.0$.

**Parameters**

- **n**: int, quadrature order
- **mu**: bool, optional

**Returns**

- **x**: ndarray, Sample points
- **w**: ndarray, Weights
- **mu**: float, Sum of the weights

**See also:**

*scipy.integrate.quadrature, scipy.integrate.fixed_quad, numpy.polynomial.legendre.leggauss*

**scipy.special.roots_chebyt** *(n, mu=False)*

Gauss-Chebyshev (first kind) quadrature.

Computes the sample points and weights for Gauss-Chebyshev quadrature. The sample points are the roots of the n-th degree Chebyshev polynomial of the first kind, $T_n(x)$. These sample points and weights correctly integrate polynomials of degree $2n-1$ or less over the interval $[-1, 1]$ with weight function $f(x) = 1/\sqrt{1 - x^2}$.

**Parameters**

- **n**: int, quadrature order
SciPy Reference Guide, Release 1.0.0

\[ \textbf{mu} : \text{bool, optional} \]

Returns

\[ \text{x} : \text{ndarray} \]
Sample points

\[ \text{w} : \text{ndarray} \]
Weights

\[ \text{mu} : \text{float} \]
Sum of the weights

See also:

\[ \text{scipy.integrate.quadrature, scipy.integrate.fixed_quad, numpy.polynomial.chebyshev.chebgauss} \]

`scipy.special.roots_chebyu(n, mu=False)`

Gauss-Chebyshev (second kind) quadrature.

Computes the sample points and weights for Gauss-Chebyshev quadrature. The sample points are the roots of the \( n \)-th degree Chebyshev polynomial of the second kind, \( U_n(x) \). These sample points and weights correctly integrate polynomials of degree \( 2n - 1 \) or less over the interval \([ -1, 1 ]\) with weight function \( f(x) = \sqrt{1 - x^2} \).

Parameters

\[ n : \text{int} \]
quadrature order

\[ \text{mu} : \text{bool, optional} \]

Returns

\[ \text{x} : \text{ndarray} \]
Sample points

\[ \text{w} : \text{ndarray} \]
Weights

\[ \text{mu} : \text{float} \]
Sum of the weights

See also:

\[ \text{scipy.integrate.quadrature, scipy.integrate.fixed_quad} \]

`scipy.special.roots_chebyc(n, mu=False)`

Gauss-Chebyshev (first kind) quadrature.

Computes the sample points and weights for Gauss-Chebyshev quadrature. The sample points are the roots of the \( n \)-th degree Chebyshev polynomial of the first kind, \( C_n(x) \). These sample points and weights correctly integrate polynomials of degree \( 2n - 1 \) or less over the interval \([ -2, 2 ]\) with weight function \( f(x) = 1/\sqrt{1 - (x/2)^2} \).

Parameters

\[ n : \text{int} \]
quadrature order

\[ \text{mu} : \text{bool, optional} \]

Returns

\[ \text{x} : \text{ndarray} \]
Sample points

\[ \text{w} : \text{ndarray} \]
Weights

\[ \text{mu} : \text{float} \]
Sum of the weights

See also:

\[ \text{scipy.integrate.quadrature, scipy.integrate.fixed_quad} \]

`scipy.special.roots_chebys(n, mu=False)`

Gauss-Chebyshev (second kind) quadrature.
Computes the sample points and weights for Gauss-Chebyshev quadrature. The sample points are the roots of the n-th degree Chebyshev polynomial of the second kind, $S_n(x)$. These sample points and weights correctly integrate polynomials of degree $2n - 1$ or less over the interval $[-2, 2]$ with weight function $f(x) = \sqrt{1 - (x/2)^2}$.

**Parameters**
- $n$: int
  - quadrature order
- $mu$: bool, optional

**Returns**
- $x$: ndarray
  - Sample points
- $w$: ndarray
  - Weights
- $mu$: float
  - Sum of the weights

**See also:**
- `scipy.integrate.quadrature`, `scipy.integrate.fixed_quad`
- `scipy.special.roots_jacobi($n$, alpha, beta, mu=False)`
  - Gauss-Jacobi quadrature.

Computes the sample points and weights for Gauss-Jacobi quadrature. The sample points are the roots of the n-th degree Jacobi polynomial, $P^{\alpha,\beta}_n(x)$. These sample points and weights correctly integrate polynomials of degree $2n - 1$ or less over the interval $[-1, 1]$ with weight function $f(x) = (1 - x)^{\alpha}(1 + x)^{\beta}$.

**Parameters**
- $n$: int
  - quadrature order
- $alpha$: float
  - alpha must be $> -1$
- $beta$: float
  - beta must be $> 0$
- $mu$: bool, optional

**Returns**
- $x$: ndarray
  - Sample points
- $w$: ndarray
  - Weights
- $mu$: float
  - Sum of the weights

**See also:**
- `scipy.integrate.quadrature`, `scipy.integrate.fixed_quad`
- `scipy.special.roots_laguerre($n$, mu=False)`
  - Gauss-Laguerre quadrature.

Computes the sample points and weights for Gauss-Laguerre quadrature. The sample points are the roots of the n-th degree Laguerre polynomial, $L_n(x)$. These sample points and weights correctly integrate polynomials of degree $2n - 1$ or less over the interval $[0, \infty]$ with weight function $f(x) = e^{-x}$.

**Parameters**
- $n$: int
  - quadrature order
- $mu$: bool, optional

**Returns**
- $x$: ndarray
  - Sample points
- $w$: ndarray
  - Weights
- $mu$: float
  - Sum of the weights
Sum of the weights

See also:

scipy.integrate.quadrature, scipy.integrate.fixed_quad, numpy.polynomial.laguerre.laggauss

scipy.special.**roots_genlaguerre**(*n, alpha, mu=False*)

Gauss-generalized Laguerre quadrature.

Computes the sample points and weights for Gauss-generalized Laguerre quadrature. The sample points are the roots of the n-th degree generalized Laguerre polynomial, \(L_\alpha^n(x)\). These sample points and weights correctly integrate polynomials of degree \(2n - 1\) or less over the interval \([0, \infty]\) with weight function \(f(x) = x^\alpha e^{-x}\).

**Parameters**

- **n**: int
  - Quadrature order

- **alpha**: float
  - \(alpha\) must be > -1

- **mu**: bool, optional

**Returns**

- **x**: ndarray
  - Sample points

- **w**: ndarray
  - Weights

- **mu**: float
  - Sum of the weights

See also:

scipy.integrate.quadrature, scipy.integrate.fixed_quad

scipy.special.**roots_hermite**(*n, mu=False*)

Gauss-Hermite (physicist’s) quadrature.

Computes the sample points and weights for Gauss-Hermite quadrature. The sample points are the roots of the n-th degree Hermite polynomial, \(H_n(x)\). These sample points and weights correctly integrate polynomials of degree \(2n - 1\) or less over the interval \([-\infty, \infty]\) with weight function \(f(x) = e^{-x^2}\).

**Parameters**

- **n**: int
  - Quadrature order

- **mu**: bool, optional

**Returns**

- **x**: ndarray
  - Sample points

- **w**: ndarray
  - Weights

- **mu**: float
  - Sum of the weights

See also:

scipy.integrate.quadrature, scipy.integrate.fixed_quad, numpy.polynomial.hermite.hermgauss, roots_hermitenorm

**Notes**

For small n up to 150 a modified version of the Golub-Welsch algorithm is used. Nodes are computed from the eigenvalue problem and improved by one step of a Newton iteration. The weights are computed from the well-known analytical formula.
For $n$ larger than 150 an optimal asymptotic algorithm is applied which computes nodes and weights in a numerically stable manner. The algorithm has linear runtime making computation for very large $n$ (several thousand or more) feasible.

**Notes**

For small $n$ up to 150 a modified version of the Golub-Welsch algorithm is used. Nodes are computed from the eigenvalue problem and improved by one step of a Newton iteration. The weights are computed from the well-known analytical formula.

For $n$ larger than 150 an optimal asymptotic algorithm is applied which computes nodes and weights in a numerical stable manner. The algorithm has linear runtime making computation for very large $n$ (several thousand or more) feasible.

`scipy.special.roots_gegenbauer(n, alpha, mu=False)`  
Gauss-Gegenbauer quadrature.

Computes the sample points and weights for Gauss-Gegenbauer quadrature. The sample points are the roots of the $n$-th degree Gegenbauer polynomial, $C_n^\alpha(x)$. These sample points and weights correctly integrate polynomials of degree $2n - 1$ or less over the interval $[-1, 1]$ with weight function $f(x) = (1 - x^2)^{\alpha-1/2}$.

**Parameters**

- `n` : int  
  Quadrature order
- `alpha` : float  
  alpha must be > -0.5
- `mu` : bool, optional

**Returns**

- `x` : ndarray  
  Sample points
- `w` : ndarray  
  Weights
- `mu` : float  
  Sum of the weights
SciPy Reference Guide, Release 1.0.0

See also:

scipy.integrate.quadrature, scipy.integrate.fixed_quad

scipy.special.roots_sh_legendre(n, mu=False)
Gauss-Legendre (shifted) quadrature.

Computes the sample points and weights for Gauss-Legendre quadrature. The sample points are the roots of the n-th degree shifted Legendre polynomial $P_n^*(x)$. These sample points and weights correctly integrate polynomials of degree $2n - 1$ or less over the interval $[0, 1]$ with weight function $f(x) = 1$.

Parameters

- n: int
  quadrature order
- mu: bool, optional

Returns

- x: ndarray
  Sample points
- w: ndarray
  Weights
- mu: float
  Sum of the weights

See also:

scipy.integrate.quadrature, scipy.integrate.fixed_quad

scipy.special.roots_sh_chebyt(n, mu=False)
Gauss-Chebyshev (first kind, shifted) quadrature.

Computes the sample points and weights for Gauss-Chebyshev quadrature. The sample points are the roots of the n-th degree shifted Chebyshev polynomial of the first kind, $T_n(x)$. These sample points and weights correctly integrate polynomials of degree $2n - 1$ or less over the interval $[0, 1]$ with weight function $f(x) = 1/\sqrt{x - x^2}$.

Parameters

- n: int
  quadrature order
- mu: bool, optional

Returns

- x: ndarray
  Sample points
- w: ndarray
  Weights
- mu: float
  Sum of the weights

See also:

scipy.integrate.quadrature, scipy.integrate.fixed_quad

scipy.special.roots_sh_chebyu(n, mu=False)
Gauss-Chebyshev (second kind, shifted) quadrature.

Computes the sample points and weights for Gauss-Chebyshev quadrature. The sample points are the roots of the n-th degree shifted Chebyshev polynomial of the second kind, $U_n(x)$. These sample points and weights correctly integrate polynomials of degree $2n - 1$ or less over the interval $[0, 1]$ with weight function $f(x) = \sqrt{x - x^2}$.

Parameters

- n: int
  quadrature order
- mu: bool, optional

Returns

- x: ndarray
  Sample points
- w: ndarray
  Weights
SciPy Reference Guide, Release 1.0.0

Weights

\( \mu \) : float
Sum of the weights

See also:

scipy.integrate.quadrature, scipy.integrate.fixed_quad

scipy.special.roots_sh_jacobi \((n, p1, q1, \mu=False)\)

Gauss-Jacobi (shifted) quadrature.

Computes the sample points and weights for Gauss-Jacobi (shifted) quadrature. The sample points are the roots of the \( n \)-th degree shifted Jacobi polynomial, \( G_n^{p,q}(x) \). These sample points and weights correctly integrate polynomials of degree \( 2n - 1 \) or less over the interval \([0, 1]\) with weight function \( f(x) = (1-x)^{p-q}x^{q-1} \).

Parameters

\( n \) : int
quadature order

\( p1 \) : float
\((p1 - q1)\) must be > -1

\( q1 \) : float
\( q1 \) must be > 0

\( \mu \) : bool, optional

Returns

\( x \) : ndarray
Sample points

\( w \) : ndarray
Weights

\( \mu \) : float
Sum of the weights

See also:

scipy.integrate.quadrature, scipy.integrate.fixed_quad

The functions below, in turn, return the polynomial coefficients in orthopoly1d objects, which function similarly as numpy.poly1d. The orthopoly1d class also has an attribute weights which returns the roots, weights, and total weights for the appropriate form of Gaussian quadrature. These are returned in an \( n \times 3 \) array with roots in the first column, weights in the second column, and total weights in the final column. Note that orthopoly1d objects are converted to poly1d when doing arithmetic, and lose information of the original orthogonal polynomial.

scipy.special.legendre \((n, \text{monic}=False)\)
Legendre polynomial.
Defined to be the solution of
\[
\frac{d}{dx} \left[ (1 - x^2) \frac{d}{dx} P_n(x) \right] + n(n+1)P_n(x) = 0;
\]

\(P_n(x)\) is a polynomial of degree \(n\).

**Parameters**
- **n**: int
  - Degree of the polynomial.
- **monic**: bool, optional
  - If True, scale the leading coefficient to be 1. Default is False.

**Returns**
P: orthopoly1d
Legendre polynomial.

**Notes**
The polynomials \(P_n\) are orthogonal over \([-1, 1]\) with weight function 1.

**Examples**
Generate the 3rd-order Legendre polynomial \(1/2*(5x^3 + 0x^2 - 3x + 0):\)

```python
>>> from scipy.special import legendre
>>> legendre(3)
poly1d([ 2.5, 0. , -1.5, 0. ])
```

scipy.special.chebyt \((n, monic=False)\)
Chebyshev polynomial of the first kind.
Defined to be the solution of
\[
(1 - x^2) \frac{d^2}{dx^2} T_n - x \frac{d}{dx} T_n + n^2 T_n = 0;
\]

\(T_n\) is a polynomial of degree \(n\).

**Parameters**
- **n**: int
  - Degree of the polynomial.
- **monic**: bool, optional
  - If True, scale the leading coefficient to be 1. Default is False.

**Returns**
T: orthopoly1d
Chebyshev polynomial of the first kind.

See also:
chebyu
Chebyshev polynomial of the second kind.

**Notes**
The polynomials \(T_n\) are orthogonal over \([-1, 1]\) with weight function \((1 - x^2)^{-1/2}\).

scipy.special.chebyu \((n, monic=False)\)
Chebyshev polynomial of the second kind.
Defined to be the solution of
\[
(1 - x^2) \frac{d^2}{dx^2} U_n - 3x \frac{d}{dx} U_n + n(n+2) U_n = 0;
\]

\(U_n\) is a polynomial of degree \(n\).

**Parameters**
- **n**: int
Degree of the polynomial.

**monic**: bool, optional

**Returns**

- **U**: orthopoly1d
  
  Chebyshev polynomial of the second kind.

**See also:**

- **chebyt**: Chebyshev polynomial of the first kind.

**Notes**

The polynomials $U_n$ are orthogonal over $[-1, 1]$ with weight function $(1 - x^2)^{1/2}$.

**scipy.special.chebyc(n, monic=False)**

Chebyshev polynomial of the first kind on $[-2, 2]$.

Defined as $C_n(x) = 2T_n(x/2)$, where $T_n$ is the nth Chebychev polynomial of the first kind.

**Parameters**

- **n**: int
  
  Degree of the polynomial.

- **monic**: bool, optional
  
  If True, scale the leading coefficient to be 1. Default is False.

**Returns**

- **C**: orthopoly1d
  
  Chebyshev polynomial of the first kind on $[-2, 2]$.

**See also:**

- **chebyt**: Chebyshev polynomial of the first kind.

**Notes**

The polynomials $C_n(x)$ are orthogonal over $[-2, 2]$ with weight function $1/\sqrt{1 - (x/2)^2}$.

**References**

[R435]

**scipy.special.chebs(n, monic=False)**

Chebyshev polynomial of the second kind on $[-2, 2]$.

Defined as $S_n(x) = U_n(x/2)$ where $U_n$ is the nth Chebychev polynomial of the second kind.

**Parameters**

- **n**: int
  
  Degree of the polynomial.

- **monic**: bool, optional
  
  If True, scale the leading coefficient to be 1. Default is False.

**Returns**

- **S**: orthopoly1d
  
  Chebyshev polynomial of the second kind on $[-2, 2]$.

**See also:**

- **chebyu**: Chebyshev polynomial of the second kind

**Notes**

The polynomials $S_n(x)$ are orthogonal over $[-2, 2]$ with weight function $\sqrt{1 - (x/2)^2}$.

**References**

[R436]
scipy.special.jacobi $(n, \alpha, \beta, \text{monic}=\text{False})$

Jacobi polynomial.

Defined to be the solution of

$$(1 - x^2) \frac{d^2}{dx^2} P_n^{(\alpha, \beta)} + \left( \beta - \alpha - (\alpha + \beta + 2)x \right) \frac{d}{dx} P_n^{(\alpha, \beta)} + n(n + \alpha + \beta + 1)P_n^{(\alpha, \beta)} = 0$$

for $\alpha, \beta > -1$; $P_n^{(\alpha, \beta)}$ is a polynomial of degree $n$.

**Parameters**

- $n$ : int
  Degree of the polynomial.
- $\alpha$ : float
  Parameter, must be greater than -1.
- $\beta$ : float
  Parameter, must be greater than -1.
- $\text{monic}$ : bool, optional
  If True, scale the leading coefficient to be 1. Default is False.

**Returns**

- $P$ : orthopoly1d
  Jacobi polynomial.

**Notes**

For fixed $\alpha, \beta$, the polynomials $P_n^{(\alpha, \beta)}$ are orthogonal over $[-1, 1]$ with weight function $(1 - x)^\alpha (1 + x)^\beta$.

scipy.special.laguerre $(n, \text{monic}=\text{False})$

Laguerre polynomial.

Defined to be the solution of

$$x \frac{d^2}{dx^2} L_n + (1 - x) \frac{d}{dx} L_n + nL_n = 0;$$

$L_n$ is a polynomial of degree $n$.

**Parameters**

- $n$ : int
  Degree of the polynomial.
- $\text{monic}$ : bool, optional
  If True, scale the leading coefficient to be 1. Default is False.

**Returns**

- $L$ : orthopoly1d
  Laguerre Polynomial.

**Notes**

The polynomials $L_n$ are orthogonal over $[0, \infty)$ with weight function $e^{-x}$.

scipy.special.genlaguerre $(n, \alpha, \text{monic}=\text{False})$

Generalized (associated) Laguerre polynomial.

Defined to be the solution of

$$x \frac{d^2}{dx^2} L_n^{(\alpha)} + (\alpha + 1 - x) \frac{d}{dx} L_n^{(\alpha)} + nL_n^{(\alpha)} = 0,$$

where $\alpha > -1$; $L_n^{(\alpha)}$ is a polynomial of degree $n$.

**Parameters**

- $n$ : int
  Degree of the polynomial.
- $\alpha$ : float
  Parameter, must be greater than -1.
- $\text{monic}$ : bool, optional
  If True, scale the leading coefficient to be 1. Default is False.

**Returns**

- $L$ : orthopoly1d
  Laguerre Polynomial.
Generalized Laguerre polynomial.

See also:

laguerre  Laguerre polynomial.

Notes

For fixed $\alpha$, the polynomials $L_n^{(\alpha)}$ are orthogonal over $[0, \infty)$ with weight function $e^{-x}x^\alpha$.

The Laguerre polynomials are the special case where $\alpha = 0$.

cipy.special.hermite $(n, \text{monic=False})$

Physicist’s Hermite polynomial.

Defined by

$$H_n(x) = (-1)^n e^{x^2} \frac{d^n}{dx^n} e^{-x^2};$$

$H_n$ is a polynomial of degree $n$.

Parameters

- **n**: int
  - Degree of the polynomial.

- **monic**: bool, optional
  - If True, scale the leading coefficient to be 1. Default is False.

Returns

- **H**: orthopoly1d
  - Hermite polynomial.

Notes

The polynomials $H_n$ are orthogonal over $(-\infty, \infty)$ with weight function $e^{-x^2}$.

cipy.special.hermitenorm $(n, \text{monic=False})$

Normalized (probabilist’s) Hermite polynomial.

Defined by

$$He_n(x) = (-1)^n e^{x^2/2} \frac{d^n}{dx^n} e^{-x^2/2};$$

$He_n$ is a polynomial of degree $n$.

Parameters

- **n**: int
  - Degree of the polynomial.

- **monic**: bool, optional
  - If True, scale the leading coefficient to be 1. Default is False.

Returns

- **He**: orthopoly1d
  - Hermite polynomial.

Notes

The polynomials $He_n$ are orthogonal over $(-\infty, \infty)$ with weight function $e^{-x^2/2}$.

cipy.special.gegenbauer $(n, \alpha, \text{monic=False})$

Gegenbauer (ultraspherical) polynomial.

Defined to be the solution of

$$(1 - x^2) \frac{d^2}{dx^2} C_n^{(\alpha)} - (2\alpha + 1)x \frac{d}{dx} C_n^{(\alpha)} + n(n + 2\alpha)C_n^{(\alpha)} = 0$$

for $\alpha > -1/2$; $C_n^{(\alpha)}$ is a polynomial of degree $n$.

Parameters

- **n**: int
Degree of the polynomial.

**monic**: bool, optional

If `True`, scale the leading coefficient to be 1. Default is `False`.

**Returns**

- `C`: `orthopoly1d`
  - Gegenbauer polynomial.

**Notes**

The polynomials $C_n^{(\alpha)}$ are orthogonal over $[-1, 1]$ with weight function $(1 - x^2)^{(\alpha-1)/2}$.

```python
scipy.special.sh_legendre(n, monic=False)
```

Shifted Legendre polynomial.

Defined as $P_n^*(x) = P_n(2x - 1)$ for $P_n$ the nth Legendre polynomial.

**Parameters**

- `n`: int
  - Degree of the polynomial.

- `monic`: bool, optional

**Returns**

- `P`: `orthopoly1d`
  - Shifted Legendre polynomial.

**Notes**

The polynomials $P_n^*$ are orthogonal over $[0, 1]$ with weight function 1.

```python
scipy.special.sh_chebyt(n, monic=False)
```

Shifted Chebyshev polynomial of the first kind.

Defined as $T_n^*(x) = T_n(2x - 1)$ for $T_n$ the nth Chebyshev polynomial of the first kind.

**Parameters**

- `n`: int
  - Degree of the polynomial.

- `monic`: bool, optional

**Returns**

- `T`: `orthopoly1d`
  - Shifted Chebyshev polynomial of the first kind.

**Notes**

The polynomials $T_n^*$ are orthogonal over $[0, 1]$ with weight function $(x - x^2)^{-1/2}$.

```python
scipy.special.sh_chebyu(n, monic=False)
```

Shifted Chebyshev polynomial of the second kind.

Defined as $U_n^*(x) = U_n(2x - 1)$ for $U_n$ the nth Chebyshev polynomial of the second kind.

**Parameters**

- `n`: int
  - Degree of the polynomial.

- `monic`: bool, optional

**Returns**

- `U`: `orthopoly1d`
  - Shifted Chebyshev polynomial of the second kind.

**Notes**

The polynomials $U_n^*$ are orthogonal over $[0, 1]$ with weight function $(x - x^2)^{1/2}$.

```python
scipy.special.sh_jacobi(n, p, q, monic=False)
```

Shifted Jacobi polynomial.
Defined by

\[ G_n^{(p,q)}(x) = \binom{2n + p - 1}{n}^{-1} P_n^{(p-q,q-1)}(2x - 1), \]

where \( P_n^{(\cdot,\cdot)} \) is the nth Jacobi polynomial.

**Parameters**
- \( n \): int
  - Degree of the polynomial.
- \( p \): float
  - Parameter, must have \( p > q - 1 \).
- \( q \): float
  - Parameter, must be greater than 0.
- \( \text{monic} \): bool, optional
  - If True, scale the leading coefficient to be 1. Default is False.

**Returns**
- \( G \): orthopoly1d
  - Shifted Jacobi polynomial.

**Notes**
For fixed \( p, q \), the polynomials \( G_n^{(p,q)} \) are orthogonal over \([0, 1]\) with weight function \((1 - x)^{p-q}x^{q-1}\).

**Warning:** Computing values of high-order polynomials (around order > 20) using polynomial coefficients is numerically unstable. To evaluate polynomial values, the eval_* functions should be used instead.

### Hypergeometric Functions

<table>

<td>Hypergeometric function 3F0 in y and an error estimate</td>
</tr>
</tbody>
</table>

**scipy.special.hyp2f1(a, b, c, z) = <ufunc ‘hyp2f1’>**

Gauss hypergeometric function 2F1(a, b; c; z)

**Parameters**
- \( a, b, c \): array_like
  - Arguments, should be real-valued.
- \( z \): array_like

**Returns**
- \( \text{hyp2f1} \): scalar or ndarray
  - Argument, real or complex.
  - The values of the gaussian hypergeometric function.

**See also:**
- hyp0f1: confluent hypergeometric limit function.
- hyp1f1: Kummer’s (confluent hypergeometric) function.
Notes

This function is defined for $|z| < 1$ as

$$\text{hyp2f1}(a, b, c, z) = \sum_{n=0}^{\infty} \frac{(a)_n(b)_n}{(c)_n} z^n$$

and defined on the rest of the complex $z$-plane by analytic continuation. Here $(\cdot)_n$ is the Pochhammer symbol; see `poch`. When $n$ is an integer the result is a polynomial of degree $n$.

The implementation for complex values of $z$ is described in [R488].

References

[R488], [R489], [R490]

scipy.special.hyp1f1(a, b, x) = <ufunc 'hyp1f1'>
Confluent hypergeometric function 1F1(a, b; x)

scipy.special.hyperu(a, b, x) = <ufunc 'hyperu'>
Confluent hypergeometric function U(a, b, x) of the second kind

scipy.special.hyp0f1(v, x) = <ufunc 'hyp0f1'>
Confluent hypergeometric limit function 0F1.

Parameters
- v, z : array_like
  Input values.

Returns
- hyp0f1 : ndarray
  The confluent hypergeometric limit function.

Notes

This function is defined as:

$$0F1(v, z) = \sum_{k=0}^{\infty} \frac{z^k}{(v)_k k!}.$$  

It’s also the limit as $q \rightarrow \infty$ of $1F1(q; v; z/q)$, and satisfies the differential equation $f''(z) + vf'(z) = f(z)$.

scipy.special.hyp2f0(a, b, x, type) = <ufunc 'hyp2f0'>
Hypergeometric function 2F0 in $y$ and an error estimate

The parameter `type` determines a convergence factor and can be either 1 or 2.

Returns
- y : Value of the function
- err : Error estimate

scipy.special.hyp1f2(a, b, c, x) = <ufunc 'hyp1f2'>
Hypergeometric function 1F2 and error estimate

Returns
- y : Value of the function
- err : Error estimate

scipy.special.hyp3f0(a, b, c, x) = <ufunc 'hyp3f0'>
Hypergeometric function 3F0 in $y$ and an error estimate

Returns
- y : Value of the function
- err : Error estimate
Parabolic Cylinder Functions

\begin{verbatim}
import scipy.special

# Parabolic cylinder function D
pbdv(v, x) = <ufunc 'pbdv'>
Returns (d, dp) the parabolic cylinder function Dv(x) in d and the derivative, Dv'(x) in dp.

Returns
- d: Value of the function
- dp: Value of the derivative vs x

# Parabolic cylinder function V
pbvv(v, x) = <ufunc 'pbvv'>
Returns the parabolic cylinder function Vv(x) in v and the derivative, Vv'(x) in vp.

Returns
- v: Value of the function
- vp: Value of the derivative vs x

# Parabolic cylinder function W
pbwa(a, x) = <ufunc 'pbwa'>
The function is a particular solution to the differential equation
\[ y'' + \left(\frac{1}{4}x^2 - a\right)y = 0, \]
for a full definition see section 12.14 in [R559].

Parameters
- a: array_like: Real parameter
- x: array_like: Real argument

Returns
- w: scalar or ndarray: Value of the function
- wp: scalar or ndarray: Value of the derivative in x

Notes
The function is a wrapper for a Fortran routine by Zhang and Jin [R560]. The implementation is accurate only for \(|a|, |x| < 5\) and returns NaN outside that range.

References
[R559], [R560]

These are not universal functions:

- pbdv_seq(v, x): Parabolic cylinder functions Dv(x) and derivatives.
- pbvv_seq(v, x): Parabolic cylinder functions Vv(x) and derivatives.
- pbdn_seq(n, z): Parabolic cylinder functions Dn(z) and derivatives.
\end{verbatim}

scipy.special.pbdv_seq(v, x)
Parabolic cylinder functions Dv(x) and derivatives.

**Parameters**
- v : float
  - Order of the parabolic cylinder function
- x : float
  - Value at which to evaluate the function and derivatives

**Returns**
- dv : ndarray
  - Values of D_vi(x), for vi=v-int(v), vi=1+v-int(v), ..., vi=v.
- dp : ndarray
  - Derivatives D_vi'(x), for vi=v-int(v), vi=1+v-int(v), ..., vi=v.

**References**
[R557]

scipy.special.pbvv_seq(v, x)
Parabolic cylinder functions Vv(x) and derivatives.

**Parameters**
- v : float
  - Order of the parabolic cylinder function
- x : float
  - Value at which to evaluate the function and derivatives

**Returns**
- dv : ndarray
  - Values of V_vi(x), for vi=v-int(v), vi=1+v-int(v), ..., vi=v.
- dp : ndarray
  - Derivatives V_vi'(x), for vi=v-int(v), vi=1+v-int(v), ..., vi=v.

**References**

scipy.special.pbdn_seq(n, z)
Parabolic cylinder functions Dn(z) and derivatives.

**Parameters**
- n : int
  - Order of the parabolic cylinder function
- z : complex
  - Value at which to evaluate the function and derivatives

**Returns**
- dv : ndarray
  - Values of D_i(z), for i=0, ..., i=n.
- dp : ndarray
  - Derivatives D_i'(z), for i=0, ..., i=n.

**References**
[R556]
Characteristic value of odd Mathieu functions

Returns the characteristic value for the odd solution, $se_m(z, q)$, of Mathieu’s equation.

These are not universal functions:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>mathieu_even_coef(m, q)</code></td>
<td>Fourier coefficients for even Mathieu and modified Mathieu functions.</td>
</tr>
<tr>
<td><code>mathieu_odd_coef(m, q)</code></td>
<td>Fourier coefficients for even Mathieu and modified Mathieu functions.</td>
</tr>
</tbody>
</table>

**scipy.special.mathieu_even_coef** ($m, q$)

Fourier coefficients for even Mathieu and modified Mathieu functions.

The Fourier series of the even solutions of the Mathieu differential equation are of the form

$$cc_{2n}(z, q) = \sum_{k=0}^{\infty} A_{(2n)}^{(2k)} \cos 2kz$$

$$cc_{2n+1}(z, q) = \sum_{k=0}^{\infty} A_{(2n+1)}^{(2k+1)} \cos(2k+1)z$$

This function returns the coefficients $A_{(2n)}^{(2k)}$ for even input $m=2n$, and the coefficients $A_{(2n+1)}^{(2k+1)}$ for odd input $m=2n+1$.

**Parameters**

- $m$: int
  - Order of Mathieu functions. Must be non-negative.
- $q$: float ($\geq 0$)

**Returns**

- $Ak$: ndarray
  - Parameter of Mathieu functions. Must be non-negative.
  - Even or odd Fourier coefficients, corresponding to even or odd $m$.

**References**

[R542], [R543]

**scipy.special.mathieu_odd_coef** ($m, q$)

Fourier coefficients for even Mathieu and modified Mathieu functions.

The Fourier series of the odd solutions of the Mathieu differential equation are of the form

$$se_{2n+1}(z, q) = \sum_{k=0}^{\infty} B_{(2n+1)}^{(2k+1)} \sin(2k+1)z$$

$$se_{2n+2}(z, q) = \sum_{k=0}^{\infty} B_{(2n+2)}^{(2k+2)} \sin(2k+2)z$$

This function returns the coefficients $B_{(2n+1)}^{(2k+1)}$ for even input $m=2n+2$, and the coefficients $B_{(2n+1)}^{(2k+1)}$ for odd input $m=2n+1$.

**Parameters**

- $m$: int
  - Order of Mathieu functions. Must be non-negative.
- $q$: float ($\geq 0$)

**Returns**

- $Bk$: ndarray
  - Parameter of Mathieu functions. Must be non-negative.
  - Even or odd Fourier coefficients, corresponding to even or odd $m$. 
The following return both function and first derivative:

<table>

</tbody>
</table>

scipy.special.\texttt{mathieu\_cem}(m, q, x) = <ufunc ‘mathieu\_cem’>

Even Mathieu function and its derivative

Returns the even Mathieu function, \(ce_m(x, q)\), of order \(m\) and parameter \(q\) evaluated at \(x\) (given in degrees). Also returns the derivative with respect to \(x\) of \(ce_m(x, q)\).

**Parameters**
- \(m\) : Order of the function
- \(q\) : Parameter of the function
- \(x\) : Argument of the function, given in degrees, not radians

**Returns**
- \(y\) : Value of the function
- \(yp\) : Value of the derivative vs \(x\)

scipy.special.\texttt{mathieu\_sem}(m, q, x) = <ufunc ‘mathieu\_sem’>

Odd Mathieu function and its derivative

Returns the odd Mathieu function, \(se_m(x, q)\), of order \(m\) and parameter \(q\) evaluated at \(x\) (given in degrees). Also returns the derivative with respect to \(x\) of \(se_m(x, q)\).

**Parameters**
- \(m\) : Order of the function
- \(q\) : Parameter of the function
- \(x\) : Argument of the function, given in degrees, not radians.

**Returns**
- \(y\) : Value of the function
- \(yp\) : Value of the derivative vs \(x\)

scipy.special.\texttt{mathieu\_modcem1}(m, q, x) = <ufunc ‘mathieu\_modcem1’>

Even modified Mathieu function of the first kind and its derivative

Evaluates the even modified Mathieu function of the first kind, \(Mc1m(x, q)\), and its derivative at \(x\) for order \(m\) and parameter \(q\).

**Returns**
- \(y\) : Value of the function
Value of the derivative vs x

scipy.special.mathieu_modcem2 \( (m, q, x) \) = <ufunc 'mathieu_modcem2'>
Even modified Mathieu function of the second kind and its derivative

Evaluates the even modified Mathieu function of the second kind, \( Mc2m(x, q) \), and its derivative at \( x \) (given in degrees) for order \( m \) and parameter \( q \).

Returns
- \( y \) Value of the function
- \( yp \) Value of the derivative vs \( x \)

scipy.special.mathieu_modsem1 \( (m, q, x) \) = <ufunc 'mathieu_modsem1'>
Odd modified Mathieu function of the first kind and its derivative

Evaluates the odd modified Mathieu function of the first kind, \( Ms1m(x, q) \), and its derivative at \( x \) (given in degrees) for order \( m \) and parameter \( q \).

Returns
- \( y \) Value of the function
- \( yp \) Value of the derivative vs \( x \)

scipy.special.mathieu_modsem2 \( (m, q, x) \) = <ufunc 'mathieu_modsem2'>
Odd modified Mathieu function of the second kind and its derivative

Evaluates the odd modified Mathieu function of the second kind, \( Ms2m(x, q) \), and its derivative at \( x \) (given in degrees) for order \( m \) and parameter \( q \).

Returns
- \( y \) Value of the function
- \( yp \) Value of the derivative vs \( x \)

Spheroidal Wave Functions

pro_ang1\( (m, n, c, x) \) Prolate spheroidal angular function of the first kind and its derivative

**scipy.special.kelvin(x)**
Kelvin functions as complex numbers

**Returns**
Be, Ke, Bep, Kep

The tuple (Be, Ke, Bep, Kep) contains complex numbers representing the
real and imaginary Kelvin functions and their derivatives evaluated at x.
For example, kelvin(x)[0].real = ber x and kelvin(x)[0].imag = bei x with
similar relationships for ker and kei.

**scipy.special.kelvin_zeros(nt)**
Compute nt zeros of all Kelvin functions.

Returned in a length-8 tuple of arrays of length nt. The tuple contains the arrays of zeros of (ber, bei, ker, kei,
ber’, bei’, ker’, kei’).

Combinatorics

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \text{comb}(N, k[,\text{exact, repetition}]) )</td>
<td>The number of combinations of ( N ) things taken ( k ) at a time.</td>
</tr>
<tr>
<td>( \text{perm}(N, k[,\text{exact}]) )</td>
<td>Permutations of ( N ) things taken ( k ) at a time, i.e., ( k )-permutations of ( N ).</td>
</tr>
</tbody>
</table>

scipy.special.\text{comb}(N, k, exact=False, repetition=False)

The number of combinations of \( N \) things taken \( k \) at a time.

This is often expressed as “\( N \) choose \( k \)”.

**Parameters**

- \( N \) : int, ndarray
  Number of things.
- \( k \) : int, ndarray
  Number of elements taken.
- \( \text{exact} \) : bool, optional
  If \( \text{exact} \) is False, then floating point precision is used, otherwise exact long integer is computed.
- \( \text{repetition} \) : bool, optional
  If \( \text{repetition} \) is True, then the number of combinations with repetition is computed.

**Returns**

- \( \text{val} \) : int, float, ndarray
  The total number of combinations.

See also:

- \text{binom}  Binomial coefficient ufunc

**Notes**

- Array arguments accepted only for exact=False case.
- If \( k > N, N < 0, \) or \( k < 0 \), then a 0 is returned.

**Examples**

```python
>>> from scipy.special import comb
>>> k = np.array([3, 4])
>>> n = np.array([10, 10])
>>> comb(n, k, exact=False)
array([ 120., 210.])
>>> comb(10, 3, exact=True)
120L
>>> comb(10, 3, exact=True, repetition=True)
220L
```

scipy.special.\text{perm}(N, k, exact=False)

Permutations of \( N \) things taken \( k \) at a time, i.e., \( k \)-permutations of \( N \).

It’s also known as “partial permutations”.

**Parameters**

- \( N \) : int, ndarray
  Number of things.
- \( k \) : int, ndarray
  Number of elements taken.
**exact** : bool, optional

If `exact` is False, then floating point precision is used, otherwise exact long integer is computed.

**Returns**

`val` : int, ndarray

The number of k-permutations of N.

**Notes**

* Array arguments accepted only for exact=False case.
* If k > N, N < 0, or k < 0, then a 0 is returned.

**Examples**

```python
>>> from scipy.special import perm
>>> k = np.array([3, 4])
>>> n = np.array([10, 10])
>>> perm(n, k)
array([ 720., 5040.])
>>> perm(10, 3, exact=True)
720
```

**Lambert W and Related Functions**

- `lambertw(z[, k, tol])` Lambert W function.
- `wrightomega(z[, out])` Wright Omega function.

**Other Special Functions**

- `agm(a, b)` Compute the arithmetic-geometric mean of a and b.
- `bernioulli(n)` Bernoulli numbers B0..Bn (inclusive).
- `binom(n, k)` Binomial coefficient.
- `diric(x, n)` Periodic sinc function, also called the Dirichlet function.
- `euler(n)` Euler numbers E0.En (inclusive).
- `expn(n, x)` Exponential integral E_n.
- `exp1(z)` Exponential integral E_1 of complex argument z.
- `expi(x)` Exponential integral Ei.
- `factorial(n[, exact])` The factorial of a number or array of numbers.
- `factorial2(n[, exact])` Double factorial.
- `factorialk(n, k[, exact])` Multifactorial of n of order k, n(!...!).
- `shichi(x[, out])` Hyperbolic sine and cosine integrals.
- `sicix(x[, out])` Sine and cosine integrals.
- `spence(x[, out])` Spence’s function, also known as the dilogarithm.
- `zeta(x[, q, out])` Riemann or Hurwitz zeta function.
- `zetac(x)` Riemann zeta function minus 1.

```python
scipy.special.agm(a, b) = <ufunc 'agm'>
```

Compute the arithmetic-geometric mean of a and b.

Start with a_0 = a and b_0 = b and iteratively compute:

```
a_{n+1} = (a_n + b_n)/2
b_{n+1} = \sqrt{a_n*b_n}
```
a_n and b_n converge to the same limit as n increases; their common limit is agm(a, b).

**Parameters**  
a, b : array_like
Real values only. If the values are both negative, the result is negative. If one value is negative and the other is positive, *nan* is returned.

**Returns**  
float
The arithmetic-geometric mean of *a* and *b*.

**Examples**

```python
>>> from scipy.special import agm
>>> a, b = 24.0, 6.0
>>> agm(a, b)
13.458171481725614
```

Compare that result to the iteration:

```python
>>> while a != b:
...     a, b = (a + b)/2, np.sqrt(a*b)
...     print("a = %19.16f  b=%19.16f" % (a, b))
...     a = 15.0000000000000000 b=12.0000000000000000
     a = 13.5000000000000000 b=13.4164078649987388
     a = 13.4582039324993694 b=13.45813903999850
     a = 13.4581714817451772 b=13.4581714817060547
     a = 13.4581714817256159 b=13.4581714817256159
```

When array-like arguments are given, broadcasting applies:

```python
>>> a = np.array([[1.5], [3], [6]])  # a has shape (3, 1).
>>> b = np.array([6, 12, 24, 48])  # b has shape (4,).
>>> agm(a, b)
array([[ 3.36454287,  5.42363427,  9.05798751, 15.53650756],
       [ 4.37037309,  6.72908574, 10.84726853, 18.11597502],
       [ 6.   ,  8.74074619, 13.45817148, 21.69453707]])
```

**scipy.special.bernoulli(n)**  
Bernoulli numbers B0..Bn (inclusive).

**References**

[R426]  

**scipy.special.binom(n, k) = <ufunc ‘binom’>**  
Binomial coefficient

**See also:**
comb  
The number of combinations of N things taken k at a time.

**scipy.special.diric(x, n)**  
Periodic sinc function, also called the Dirichlet function.

The Dirichlet function is defined as:

```python
diric(x) = sin(x * n/2) / (n * sin(x / 2)),
```

where *n* is a positive integer.

**Parameters**  
x : array_like
Input data
The following example demonstrates that \texttt{diric} gives the magnitudes (modulo the sign and scaling) of the...
Fourier coefficients of a rectangular pulse.

Suppress output of values that are effectively 0:

```python
np.set_printoptions(suppress=True)
```

Create a signal $x$ of length $m$ with $k$ ones:

```python
m = 8
k = 3
x = np.zeros(m)
x[:k] = 1
```

Use the FFT to compute the Fourier transform of $x$, and inspect the magnitudes of the coefficients:

```python
np.abs(np.fft.fft(x))
```

Now find the same values (up to sign) using `diric`. We multiply by $k$ to account for the different scaling conventions of `numpy.fft.fft` and `diric`:

```python
theta = np.linspace(0, 2*np.pi, m, endpoint=False)
k * special.diric(theta, k)
```

References

[R463]

scipy.special.euler($n$)

Euler numbers E0..En (inclusive).

scipy.special.expn($n$, $x$) = <ufunc ‘expn’>

Exponential integral $E_n$

Returns the exponential integral for integer $n$ and non-negative $x$ and $n$:

\[
\int \frac{e^{-x t}}{t^n} dt, \quad t=1..\infty.
\]

scipy.special.exp1($z$) = <ufunc ‘exp1’>

Exponential integral $E_1$ of complex argument $z$

\[
\int \frac{e^{-z t}}{t} dt, \quad t=1..\infty.
\]

scipy.special.expi($x$) = <ufunc ‘expi’>

Exponential integral $Ei$

Defined as:

\[
\int \frac{e^{t}}{t} dt, \quad t=-\infty..x
\]

See `expn` for a different exponential integral.

scipy.special.factorial($n$, exact=False)

The factorial of a number or array of numbers.

The factorial of non-negative integer $n$ is the product of all positive integers less than or equal to $n$:
SciPy Reference Guide, Release 1.0.0

\[ n! = n \times (n-1) \times (n-2) \times \ldots \times 1 \]

**Parameters**

- **n**: int or array_like of ints
  
  Input values. If \( n < 0 \), the return value is 0.

- **exact**: bool, optional
  
  If True, calculate the answer exactly using long integer arithmetic. If False, result is approximated in floating point rapidly using the `gamma` function. Default is False.

**Returns**

- **nf**: float or int or ndarray
  
  Factorial of \( n \), as integer or float depending on `exact`.

**Notes**

For arrays with `exact=True`, the factorial is computed only once, for the largest input, with each other result computed in the process. The output dtype is increased to int64 or object if necessary.

With `exact=False` the factorial is approximated using the gamma function:

\[ n! = \Gamma(n + 1) \]

**Examples**

```python
>>> from scipy.special import factorial
>>> arr = np.array([3, 4, 5])
>>> factorial(arr, exact=False)
array([ 6., 24., 120.])
>>> factorial(arr, exact=True)
array([ 6, 24, 120])
>>> factorial(5, exact=True)
120L
```

scipy.special.factorial2 \((n, exact=False)\)

Double factorial.

This is the factorial with every second value skipped. E.g., \(7!! = 7 \times 5 \times 3 \times 1\). It can be approximated numerically as:

\[
\begin{align*}
    n!! &= \text{special.gamma}(n/2+1) \times 2^{(m+1)/2} / \sqrt{\pi} & \text{n odd} \\
    &= 2^{(n/2)} \times (n/2)! & \text{n even}
\end{align*}
\]

**Parameters**

- **n**: int or array_like
  
  Calculate \( n!! \). Arrays are only supported with `exact` set to False. If \( n < 0 \), the return value is 0.

- **exact**: bool, optional
  
  The result can be approximated rapidly using the gamma-formula above (default). If `exact` is set to True, calculate the answer exactly using integer arithmetic.

**Returns**

- **nff**: float or int
  
  Double factorial of \( n \), as an int or a float depending on `exact`.

**Examples**

```python
>>> from scipy.special import factorial2
>>> factorial2(7, exact=False)
array(105.00000000000001)
>>> factorial2(7, exact=True)
105L
```
scipy.special.factorialk($n$, $k$, exact=True)

Multifactorial of $n$ of order $k$, $n(!!...!)$.

This is the multifactorial of $n$ skipping $k$ values. For example,

```python
factorialk(17, 4) = 17!!!! = 17 * 13 * 9 * 5 * 1
```

In particular, for any integer $n$, we have

```
factorialk(n, 1) = factorial(n)
factorialk(n, 2) = factorial2(n)
```

**Parameters**
- **n**: int  
  Calculate multifactorial. If $n < 0$, the return value is 0.
- **k**: int  
  Order of multifactorial.
- **exact**: bool, optional  
  If exact is set to True, calculate the answer exactly using integer arithmetic.

**Returns**
- **val**: int  
  Multifactorial of $n$.

**Raises**
- **NotImplementedError**  
  Raises when exact is False

**Examples**

```python
>>> from scipy.special import factorialk
>>> factorialk(5, 1, exact=True)
120L
>>> factorialk(5, 3, exact=True)
10L
```

scipy.special.shichi($x$, out=None) = <ufunc ‘shichi’>

Hyperbolic sine and cosine integrals.

The hyperbolic sine integral is

$$\int_0^x \frac{\sinh t}{t} dt$$

and the hyperbolic cosine integral is

$$\gamma + \log(x) + \int_0^x \frac{\cosh t - 1}{t} dt$$

where $\gamma$ is Euler’s constant and log is the principle branch of the logarithm.

**Parameters**
- **x**: array_like  
  Real or complex points at which to compute the hyperbolic sine and cosine integrals.

**Returns**
- **si**: ndarray  
  Hyperbolic sine integral at $x$
- **ci**: ndarray  
  Hyperbolic cosine integral at $x$

**Notes**

For real arguments with $x < 0$, chi is the real part of the hyperbolic cosine integral. For such points $\text{chi}(x)$ and $\text{chi}(x + 0j)$ differ by a factor of $1j\cdot\pi$.

For real arguments the function is computed by calling Cephes’ [R568] shichi routine. For complex arguments the algorithm is based on Mpmath’s [R569] shi and chi routines.
scipy.special.sici(x, out=None) = <ufunc 'sici'>

Sine and cosine integrals.

The sine integral is
\[ \int_0^x \frac{\sin t}{t} dt \]
and the cosine integral is
\[ \gamma + \log(x) + \int_0^x \frac{\cos t - 1}{t} dt \]
where \( \gamma \) is Euler's constant and \( \log \) is the principal branch of the logarithm.

**Parameters**
- x : array_like
  - Real or complex points at which to compute the sine and cosine integrals.

**Returns**
- si : ndarray
  - Sine integral at \( x \)
- ci : ndarray
  - Cosine integral at \( x \)

**Notes**

For real arguments with \( x < 0 \), the cosine integral is the real part of the cosine integral. For such points \( \text{ci}(x) \) and \( \text{ci}(x + 0j) \) differ by a factor of \( 1j\pi \).

For real arguments the function is computed by calling Cephes’ \([R570]\) sici routine. For complex arguments the algorithm is based on Mpmath’s \([R571]\) si and ci routines.

**References**

\([R570], [R571]\)

scipy.special.spence(z, out=None) = <ufunc 'spence'>

Spence’s function, also known as the dilogarithm.

It is defined to be
\[ \int_0^z \frac{\log(t)}{1 - t} dt \]
for complex \( z \), where the contour of integration is taken to avoid the branch cut of the logarithm. Spence’s function is analytic everywhere except the negative real axis where it has a branch cut.

**Parameters**
- z : array_like
  - Points at which to evaluate Spence’s function

**Returns**
- s : ndarray
  - Computed values of Spence’s function

**Notes**

There is a different convention which defines Spence’s function by the integral
\[ -\int_0^z \frac{\log(1 - t)}{t} dt; \]
this is our \( \text{spence}(1 - z) \).
scipy.special.zeta (x, q=None, out=None)
Riemann or Hurwitz zeta function.

Parameters
- x : array_like of float
  Input data, must be real
- q : array_like of float, optional
  Input data, must be real. Defaults to Riemann zeta.
- out : ndarray, optional
  Output array for the computed values.

See also:
- zetac

Notes
The two-argument version is the Hurwitz zeta function:
\[ \zeta(x, q) = \sum_{k=0}^{\infty} \frac{1}{(k + q)x}, \]
Riemann zeta function corresponds to \( q = 1 \).

scipy.special.zetac(x) = <ufunc ‘zetac’>
Riemann zeta function minus 1.

This function is defined as
\[ \zeta(x) = \sum_{k=2}^{\infty} \frac{1}{k^x}, \]
where \( x > 1 \).

```python
scipy.special.cbrt(x) = <ufunc 'cbrt'>
Element-wise cube root of x.

Parameters
x : array_like
    x must contain real numbers.

Returns
float
    The cube root of each value in x.

Examples
>>> from scipy.special import cbrt

>>> cbrt(8)
2.0
>>> cbrt([-8, -3, 0.125, 1.331])
array([-2., -1.44224957, 0.5 , 1.1 ])
```

```python
scipy.special.exp10(x) = <ufunc 'exp10'>
Compute 10**x element-wise.

Parameters
x : array_like
    x must contain real numbers.

Returns
float
    10**x, computed element-wise.

Examples
>>> from scipy.special import exp10

>>> exp10(3)
1000.0
>>> x = np.array([[-1, -0.5, 0], [0.5, 1, 1.5]])
>>> exp10(x)
array([[ 0.1 , 0.31622777, 1. ],
       [ 3.16227766, 10. , 31.6227766 ]])
```

```python
scipy.special.exp2(x) = <ufunc 'exp2'>
Compute 2**x element-wise.

Parameters
x : array_like
    x must contain real numbers.

Returns
float
    2**x, computed element-wise.

Examples
>>> from scipy.special import exp2

>>> exp2(3)
8.0
>>> x = np.array([[-1, -0.5, 0], [0.5, 1, 1.5]])
>>> exp2(x)
array([[ 0.5 , 0.70710678, 1. ],
       [ 1.41421356, 2. , 2.82842712]])
```

```python
scipy.special.radian(d, m, s) = <ufunc 'radian'>
Convert from degrees to radians.

Returns the angle given in (d)egrees, (m)inutes, and (s)econds in radians.
```
scipy.special.cosdg(x) = <ufunc 'cosdg'>
Cosine of the angle x given in degrees.

scipy.special.sindg(x) = <ufunc 'sindg'>
Sine of angle given in degrees

scipy.special.tandg(x) = <ufunc 'tandg'>
Tangent of angle x given in degrees.

scipy.special.cotdg(x) = <ufunc 'cotdg'>
Cotangent of the angle x given in degrees.

scipy.special.log1p(x) = <ufunc 'log1p'>
Calculates log(1+x) for use when x is near zero

scipy.special.exp1(x) = <ufunc 'exp1'>
Compute exp(x) - 1.
When x is near zero, exp(x) is near 1, so the numerical calculation of exp(x) - 1 can suffer from catastrophic loss of precision. exp1(x) is implemented to avoid the loss of precision that occurs when x is near zero.

Parameters
x: array_like
x must contain real numbers.

Returns
float
exp(x) - 1 computed element-wise.

Examples

```python
>>> from scipy.special import exp1

>>> exp1(1.0)
1.7182818284590451
>>> exp1([-0.2, -0.1, 0, 0.1, 0.2])
array([-0.18126925, -0.09516258, 0. , 0.10517092, 0.22140276])
```

The exact value of exp(7.5e-13) - 1 is:

```
7.5000000000000028212500000000703125000001318...*10**-13.
```

Here is what exp1(7.5e-13) gives:

```
>>> exp1(7.5e-13)
7.5000000000000028135e-13
```

Compare that to exp(7.5e-13) - 1, where the subtraction results in a “catastrophic” loss of precision:

```
>>> np.exp(7.5e-13) - 1
7.500666754367576e-13
```

scipy.special.cosml(x) = <ufunc 'cosml'>

\( \cos(x) - 1 \) for use when x is near zero.

scipy.special.round(x) = <ufunc 'round'>

Round to nearest integer

Returns the nearest integer to x as a double precision floating point result. If x ends in 0.5 exactly, the nearest even integer is chosen.

scipy.special.xlogy(x, y) = <ufunc 'xlogy'>

\( x \times \log(y) \) so that the result is 0 if x = 0.
Parameters

\[ x : \text{array_like} \]
Multiplier
\[ y : \text{array_like} \]
Argument

Returns

\[ z : \text{array_like} \]
Computed \( x \times \log(y) \)

Notes

New in version 0.13.0.

\[ \text{scipy.special.xlog1py}(x, y) = \text{ufunc 'xlog1py'} \]
Compute \( x \times \log1p(y) \) so that the result is 0 if \( x = 0 \).

Parameters

\[ x : \text{array_like} \]
Multiplier
\[ y : \text{array_like} \]
Argument

Returns

\[ z : \text{array_like} \]
Computed \( x \times \log1p(y) \)

Notes

New in version 0.13.0.

\[ \text{scipy.special.logsumexp}(a, axis=None, b=None, keepdims=False, return_sign=False) \]
Compute the log of the sum of exponentials of input elements.

Parameters

\[ a : \text{array_like} \]
Input array.
\[ \text{axis} : \text{None or int or tuple of ints, optional} \]
Axis or axes over which the sum is taken. By default \( \text{axis} \) is None, and all elements are summed.
New in version 0.11.0.
\[ \text{keepdims} : \text{bool, optional} \]
If this is set to True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the original array.
New in version 0.15.0.
\[ b : \text{array-like, optional} \]
Scaling factor for \( \exp(a) \) must be of the same shape as \( a \) or broadcastable to \( a \). These values may be negative in order to implement subtraction.
New in version 0.12.0.
\[ \text{return_sign} : \text{bool, optional} \]
If this is set to True, the result will be a pair containing sign information; if False, results that are negative will be returned as NaN. Default is False (no sign information).
New in version 0.16.0.

Returns

---

\[ \text{res} : \text{ndarray} \]
The result, \( \text{np.log(np.sum(np.exp(a)))} \) calculated in a numerically more stable way. If \( b \) is given then \( \text{np.log(np.sum(b*np.exp(a)))} \) is returned.

\[ \text{sgn} : \text{ndarray} \]
If \( \text{return_sign} \) is True, this will be an array of floating-point numbers matching \( \text{res} \) and +1, 0, or -1 depending on the sign of the result. If False, only one result is returned.
See also:

numpy.logaddexp, numpy.logaddexp2

Notes
Numpy has a logaddexp function which is very similar to logsumexp, but only handles two arguments. logaddexp.reduce is similar to this function, but may be less stable.

Examples

```python
>>> from scipy.special import logsumexp
>>> a = np.arange(10)
>>> np.log(np.sum(np.exp(a)))
9.4586297444267107
>>> logsumexp(a)
9.4586297444267107

With weights

```python
>>> a = np.arange(10)
>>> b = np.arange(10, 0, -1)
>>> logsumexp(a, b=b)
9.170178533034665
>>> np.log(np.sum(b*np.exp(a)))
9.170178533034647

Returning a sign flag

```python
>>> logsumexp([1,2],b=[1,-1],return_sign=True)
(1.5413248546129181, -1.0)

Notice that logsumexp does not directly support masked arrays. To use it on a masked array, convert the mask into zero weights:

```python
>>> a = np.ma.array([np.log(2), 2, np.log(3)],
...     mask=[False, True, False])
>>> b = (~a.mask).astype(int)
>>> logsumexp(a.data, b=b), np.log(5)
1.6094379124341005, 1.6094379124341005
```

scipy.special.exprel(x) = <ufunc ‘exprel’>
Relative error exponential, \((\exp(x) - 1)/x\).

When \(x\) is near zero, \(\exp(x)\) is near 1, so the numerical calculation of \(\exp(x) - 1\) can suffer from catastrophic loss of precision. exprel(x) is implemented to avoid the loss of precision that occurs when \(x\) is near zero.

Parameters

- \(x\) : ndarray
  Input array. \(x\) must contain real numbers.

Returns

- float
  \((\exp(x) - 1)/x\), computed element-wise.

See also:

expm1

Notes
New in version 0.17.0.
Examples

```python
>>> from scipy.special import exprel

>>> exprel(0.01)
1.0050167084168056
>>> exprel([-0.25, -0.1, 0, 0.1, 0.25])
array([0.88479687, 0.95162582, 1., 1.05170918, 1.13610167])

Compare exprel(5e-9) to the naive calculation. The exact value is 1.00000000250000000416....

>>> exprel(5e-9)
1.0000000025

>>> (np.exp(5e-9) - 1)/5e-9
0.99999999392252903
```

scipy.special.sinc(x)
Return the sinc function.

The sinc function is \(\sin(\pi x)/(\pi x)\).

Parameters

- **x**: ndarray
  Array (possibly multi-dimensional) of values for which to calculate \(\text{sinc}(x)\).

Returns

- **out**: ndarray
  \(\text{sinc}(x)\), which has the same shape as the input.

Notes

\(\text{sinc}(0)\) is the limit value 1.

The name sinc is short for “sine cardinal” or “sinus cardinalis”.

The sinc function is used in various signal processing applications, including in anti-aliasing, in the construction of a Lanczos resampling filter, and in interpolation.

For bandlimited interpolation of discrete-time signals, the ideal interpolation kernel is proportional to the sinc function.

References

[R572], [R573]

Examples

```python
>>> x = np.linspace(-4, 4, 41)
>>> np.sinc(x)
array([  3.8904309e-17,   4.9236278e-02,   8.4091858e-02,   8.9038438e-02,

    6.8206631e-02,   1.1643888e-01,   1.2613779e-01,   8.5044480e-02,
   -3.8980430e-17,   4.9236278e-02,   8.4091858e-02,   8.9038438e-02,
```
5.27 Statistical functions (scipy.stats)

This module contains a large number of probability distributions as well as a growing library of statistical functions.

Each univariate distribution is an instance of a subclass of `rv_continuous` (`rv_discrete` for discrete distributions):

- `rv_continuous([momtype, a, b, xtol, ...])` A generic continuous random variable class meant for subclassing.
- `rv_discrete([a, b, name, badvalue, ...])` A generic discrete random variable class meant for subclassing.
- `rv_histogram(histogram, *args, **kwargs)` Generates a distribution given by a histogram.

**class scipy.stats.rv_continuous (momtype=1, a=None, b=None, xtol=1e-14, badvalue=None, name=None, longname=None, shapes=None, extradoc=None, seed=None)**

A generic continuous random variable class meant for subclassing.

`rv_continuous` is a base class to construct specific distribution classes and instances for continuous random variables. It cannot be used directly as a distribution.

**Parameters**

- `momtype` : int, optional
  The type of generic moment calculation to use: 0 for pdf, 1 (default) for ppf.
- `a` : float, optional
  Lower bound of the support of the distribution, default is minus infinity.
- `b` : float, optional
  Upper bound of the support of the distribution, default is plus infinity.
- `xtol` : float, optional
  The tolerance for fixed point calculation for generic ppf.
- `badvalue` : float, optional
  The value in a result arrays that indicates a value that for which some argument restriction is violated, default is np.nan.
**name**: str, optional

The name of the instance. This string is used to construct the default example for distributions.

**longname**: str, optional

This string is used as part of the first line of the docstring returned when a subclass has no docstring of its own. Note: `longname` exists for backwards compatibility, do not use for new subclasses.

**shapes**: str, optional

The shape of the distribution. For example "m, n" for a distribution that takes two integers as the two shape arguments for all its methods. If not provided, shape parameters will be inferred from the signature of the private methods, `_pdf` and `_cdf` of the instance.

**extradoc**: str, optional, deprecated

This string is used as the last part of the docstring returned when a subclass has no docstring of its own. Note: `extradoc` exists for backwards compatibility, do not use for new subclasses.

**seed**: None or int or `numpy.random.RandomState` instance, optional

This parameter defines the RandomState object to use for drawing random variates. If None (or np.random), the global np.random state is used. If integer, it is used to seed the local RandomState instance. Default is None.

**Notes**

Public methods of an instance of a distribution class (e.g., `pdf`, `cdf`) check their arguments and pass valid arguments to private, computational methods (`_pdf`, `_cdf`). For `pdf(x)`, `x` is valid if it is within the support of a distribution, `self.a <= x <= self.b`. Whether a shape parameter is valid is decided by an `_argcheck` method (which defaults to checking that its arguments are strictly positive.)

**Subclassing**

New random variables can be defined by subclassing the `rv_continuous` class and re-defining at least the `_pdf` or the `_cdf` method (normalized to location 0 and scale 1).

If positive argument checking is not correct for your RV then you will also need to re-define the `_argcheck` method.

Correct, but potentially slow defaults exist for the remaining methods but for speed and/or accuracy you can over-ride:

```python
_logpdf, _cdf, _logcdf, _ppf, _rvs, _isf, _sf, _logsf
```

Rarely would you override `_isf`, `_sf` or `_logsf`, but you could.

**Methods that can be overwritten by subclasses**

```python
_rvs
_pdf
_cdf
_sf
_ppf
_isf
_stats
_munp
_entropy
_argcheck
```

There are additional (internal and private) generic methods that can be useful for cross-checking and for debugging, but might work in all cases when directly called.
A note on shapes: subclasses need not specify them explicitly. In this case, shapes will be automatically deduced from the signatures of the overridden methods (pdf, cdf etc). If, for some reason, you prefer to avoid relying on introspection, you can specify shapes explicitly as an argument to the instance constructor.

Frozen Distributions

Normally, you must provide shape parameters (and, optionally, location and scale parameters) to each call of a method of a distribution.

Alternatively, the object may be called (as a function) to fix the shape, location, and scale parameters returning a “frozen” continuous RV object:

```
rv = generic(<shape(s)>, loc=0, scale=1)
```

frozen RV object with the same methods but holding the given shape, location, and scale fixed.

Statistics

Statistics are computed using numerical integration by default. For speed you can redefine this using _stats:

- take shape parameters and return mu, mu2, g1, g2
- If you can’t compute one of these, return it as None
- Can also be defined with a keyword argument moments, which is a string composed of “m”, “v”, “s”, and/or “k”. Only the components appearing in string should be computed and returned in the order “m”, “v”, “s”, or “k” with missing values returned as None.

Alternatively, you can override _munp, which takes n and shape parameters and returns the n-th non-central moment of the distribution.

Examples

To create a new Gaussian distribution, we would do the following:

```python
>>> from scipy.stats import rv_continuous
>>> class gaussian_gen(rv_continuous):
...    "Gaussian distribution"
...    def _pdf(self, x):
...      return np.exp(-x**2 / 2.) / np.sqrt(2.0 * np.pi)
>>> gaussian = gaussian_gen(name='gaussian')
```

scipy.stats distributions are instances, so here we subclass rv_continuous and create an instance. With this, we now have a fully functional distribution with all relevant methods automagically generated by the framework.

Note that above we defined a standard normal distribution, with zero mean and unit variance. Shifting and scaling of the distribution can be done by using loc and scale parameters: gaussian.pdf(x, loc, scale) essentially computes y = (x - loc) / scale and gaussian._pdf(y) / scale.

Attributes

random_state

Get or set the RandomState object for generating random variates.

```python
rv_continuous.random_state
```

Get or set the RandomState object for generating random variates.

This can be either None or an existing RandomState object.

If None (or np.random), use the RandomState singleton used by np.random. If already a RandomState instance, use it. If an int, use a new RandomState instance seeded with seed.
### `rvs(*args, **kwds)`
Random variates of given type.

### `pdf(x, *args, **kwds)`
Probability density function at x of the given RV.

### `logpdf(x, *args, **kwds)`
Log of the probability density function at x of the given RV.

### `cdf(x, *args, **kwds)`
Cumulative distribution function of the given RV.

### `logcdf(x, *args, **kwds)`
Log of the cumulative distribution function at x of the given RV.

### `sf(x, *args, **kwds)`
Survival function (1 - cdf) at x of the given RV.

### `logsf(x, *args, **kwds)`
Log of the survival function of the given RV.

### `ppf(q, *args, **kwds)`
Percent point function (inverse of cdf) at q of the given RV.

### `isf(q, *args, **kwds)`
Inverse survival function (inverse of sf) at q of the given RV.

### `moment(n, *args, **kwds)`
n-th order non-central moment of distribution.

### `stats(*args, **kwds)`
Some statistics of the given RV.

### `entropy(*args, **kwds)`
Differential entropy of the RV.

### `expect(func, args, loc, scale, lb, ub, ...)`
Calculate expected value of a function with respect to the distribution.

### `median(*args, **kwds)`
Median of the distribution.

### `mean(*args, **kwds)`
Mean of the distribution.

### `std(*args, **kwds)`
Standard deviation of the distribution.

### `var(*args, **kwds)`
Variance of the distribution.

### `interval(alpha, *args, **kwds)`
Confidence interval with equal areas around the median.

### `__call__(*args, **kwds)`
Freeze the distribution for the given arguments.

### `fit(data, *args, **kwds)`
Return MLEs for shape (if applicable), location, and scale parameters from data.

### `fit_loc_scale(data, *args)`
Estimate loc and scale parameters from data using 1st and 2nd moments.

### `nnlf(theta, x)`
Return negative loglikelihood function.

```python
rvs(*args, **kwds)

Parameters
arg1, arg2, arg3,... : array_like
    The shape parameter(s) for the distribution (see docstring of the instance object for more information).
loc : array_like, optional
    Location parameter (default=0).
scale : array_like, optional
    Scale parameter (default=1).
size : int or tuple of ints, optional
    Defining number of random variates (default is 1).

Returns
rvs : ndarray or scalar
    Random variates of given size.
```

```python
pdf(x, *args, **kwds)

Parameters
x : array_like
    quantiles
arg1, arg2, arg3,... : array_like
```

1692 Chapter 5. API Reference
The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc : array_like, optional
location parameter (default=0)

scale : array_like, optional

Returns pdf : ndarray
scale parameter (default=1)

Probability density function evaluated at x

rv_continuous.logpdf(x, *args, **kwds)
Log of the probability density function at x of the given RV. This uses a more numerically accurate calculation if available.

Parameters x : array_like
quantiles

arg1, arg2, arg3,... : array_like
The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc : array_like, optional
location parameter (default=0)

scale : array_like, optional
scale parameter (default=1)

Returns logpdf : array_like
Log of the probability density function evaluated at x

rv_continuous.cdf(x, *args, **kwds)
Cumulative distribution function of the given RV.

Parameters x : array_like
quantiles

arg1, arg2, arg3,... : array_like
The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc : array_like, optional
location parameter (default=0)

scale : array_like, optional
scale parameter (default=1)

Returns cdf : ndarray
Cumulative distribution function evaluated at x

rv_continuous.logcdf(x, *args, **kwds)
Log of the cumulative distribution function at x of the given RV.

Parameters x : array_like
quantiles

arg1, arg2, arg3,... : array_like
The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc : array_like, optional
location parameter (default=0)

scale : array_like, optional
scale parameter (default=1)

Returns logcdf : array_like
Log of the cumulative distribution function evaluated at x

rv_continuous.sf(x, *args, **kwds)
Survival function (1 - cdf) at x of the given RV.

Parameters x : array_like
quantiles
arg1, arg2, arg3,... : array_like
    The shape parameter(s) for the distribution (see docstring of the in-
    stance object for more information)
loc : array_like, optional
    location parameter (default=0)
scale : array_like, optional
    scale parameter (default=1)

Returns  sf : array_like
    Survival function evaluated at x

rv_continuous.logsf(x,*args,**kwds)
    Log of the survival function of the given RV.

    Returns the log of the “survival function,” defined as \(1 - \text{cdf}\), evaluated at \(x\).

Parameters  x : array_like
    quantiles
arg1, arg2, arg3,... : array_like
    The shape parameter(s) for the distribution (see docstring of the in-
    stance object for more information)
loc : array_like, optional
    location parameter (default=0)
scale : array_like, optional
    scale parameter (default=1)

Returns  logsf : ndarray
    Log of the survival function evaluated at \(x\).

rv_continuous.ppf(q,*args,**kwds)
    Percent point function (inverse of \(\text{cdf}\)) at \(q\) of the given RV.

Parameters  q : array_like
    lower tail probability
arg1, arg2, arg3,... : array_like
    The shape parameter(s) for the distribution (see docstring of the in-
    stance object for more information)
loc : array_like, optional
    location parameter (default=0)
scale : array_like, optional
    scale parameter (default=1)

Returns  x : array_like
    quantile corresponding to the lower tail probability \(q\).

rv_continuous.isf(q,*args,**kwds)
    Inverse survival function (inverse of \(\text{sf}\)) at \(q\) of the given RV.

Parameters  q : array_like
    upper tail probability
arg1, arg2, arg3,... : array_like
    The shape parameter(s) for the distribution (see docstring of the in-
    stance object for more information)
loc : array_like, optional
    location parameter (default=0)
scale : array_like, optional
    scale parameter (default=1)

Returns  x : ndarray or scalar
    Quantile corresponding to the upper tail probability \(q\).

rv_continuous.moment(n,*args,**kwds)
    n-th order non-central moment of distribution.
Parameters

- **n**: int, n >= 1  
  Order of moment.
- **arg1, arg2, arg3,...**: float  
  The shape parameter(s) for the distribution (see docstring of the instance object for more information).
- **loc**: array_like, optional  
  Location parameter (default=0)
- **scale**: array_like, optional  
  Scale parameter (default=1)

`rv_continuous.stats(*args, **kwds)`

Some statistics of the given RV.

Parameters

- **arg1, arg2, arg3,...**: array_like  
  The shape parameter(s) for the distribution (see docstring of the instance object for more information)
- **loc**: array_like, optional  
  Location parameter (default=0)
- **scale**: array_like, optional (continuous RVs only)  
  Scale parameter (default=1)
- **moments**: str, optional  
  Composed of letters ['mvsk'] defining which moments to compute: ‘m’ = mean, ‘v’ = variance, ‘s’ = (Fisher’s) skew, ‘k’ = (Fisher’s) kurtosis. (default is ‘mv’)

Returns

- **stats**: sequence  
  Of requested moments.

`rv_continuous.entropy(*args, **kwds)`

Differential entropy of the RV.

Parameters

- **arg1, arg2, arg3,...**: array_like  
  The shape parameter(s) for the distribution (see docstring of the instance object for more information).
- **loc**: array_like, optional  
  Location parameter (default=0).
- **scale**: array_like, optional (continuous distributions only)  
  Scale parameter (default=1).

Notes

Entropy is defined base e:

```python
>>> drv = rv_discrete(values=((0, 1), (0.5, 0.5)))
>>> np.allclose(drv.entropy(), np.log(2.0))
True
```

`rv_continuous.expect(func=None, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)`

Calculate expected value of a function with respect to the distribution.

The expected value of a function \( f(x) \) with respect to a distribution \( \text{dist} \) is defined as:

\[
E[x] = \int_{lb}^{ub} f(x) \times \text{dist.pdf}(x) \, dx
\]

Parameters

- **func**: callable, optional
Function for which integral is calculated. Takes only one argument. The default is the identity mapping \( f(x) = x \).

**args** : tuple, optional
Shape parameters of the distribution.

**loc** : float, optional
Location parameter (default=0).

**scale** : float, optional
Scale parameter (default=1).

**lb, ub** : scalar, optional
Lower and upper bound for integration. Default is set to the support of the distribution.

**conditional** : bool, optional
If True, the integral is corrected by the conditional probability of the integration interval. The return value is the expectation of the function, conditional on being in the given interval. Default is False.

**Returns**
- **expect** : float
  The calculated expected value.

**Notes**
The integration behavior of this function is inherited from `integrate.quad`.

```python
calculate_function(*args, **kwds)
```
Median of the distribution.

**Parameters**
- **arg1, arg2, arg3,...** : array_like
  The shape parameter(s) for the distribution (see docstring of the instance object for more information)
- **loc** : array_like, optional
  Location parameter, Default is 0.
- **scale** : array_like, optional
  Scale parameter, Default is 1.

**Returns**
- **median** : float
  The median of the distribution.

See also:
- `stats.distributions.rv_discrete.ppf`
  Inverse of the CDF

```python
calculate_function(*args, **kwds)
```
Mean of the distribution.

**Parameters**
- **arg1, arg2, arg3,...** : array_like
  The shape parameter(s) for the distribution (see docstring of the instance object for more information)
- **loc** : array_like, optional
  Location parameter (default=0)
- **scale** : array_like, optional
  Scale parameter (default=1)

**Returns**
- **mean** : float
  The mean of the distribution

```python
calculate_function(*args, **kwds)
```
Standard deviation of the distribution.

**Parameters**
- **arg1, arg2, arg3,...** : array_like
  The shape parameter(s) for the distribution (see docstring of the instance object for more information)
loc : array_like, optional
location parameter (default=0)

scale : array_like, optional
scale parameter (default=1)

Returns

std : float
standard deviation of the distribution

rv_continuous.var (*args, **kwds)
Variance of the distribution.

Parameters

arg1, arg2, arg3,... : array_like
The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc : array_like, optional
location parameter (default=0)

scale : array_like, optional
scale parameter (default=1)

Returns

var : float
the variance of the distribution

rv_continuous.interval (alpha, *args, **kwds)
Confidence interval with equal areas around the median.

Parameters

alpha : array_like of float
Probability that an rv will be drawn from the returned range. Each value should be in the range [0, 1].

arg1, arg2, ... : array_like
The shape parameter(s) for the distribution (see docstring of the instance object for more information).

loc : array_like, optional
location parameter, Default is 0.

scale : array_like, optional
scale parameter, Default is 1.

Returns

a, b : ndarray of float
end-points of range that contain 100 * alpha % of the rv's possible values.

rv_continuous.__call__ (*args, **kwds)
Freeze the distribution for the given arguments.

Parameters

arg1, arg2, arg3,... : array_like
The shape parameter(s) for the distribution. Should include all the non-optional arguments, may include loc and scale.

Returns

rv_frozen : rv_frozen instance
The frozen distribution.

rv_continuous.fit (data, *args, **kwds)
Return MLEs for shape (if applicable), location, and scale parameters from data.

MLE stands for Maximum Likelihood Estimate. Starting estimates for the fit are given by input arguments; for any arguments not provided with starting estimates, self._fitstart (data) is called to generate such.

One can hold some parameters fixed to specific values by passing in keyword arguments f0, f1, ..., fn (for shape parameters) and floc and fscale (for location and scale parameters, respectively).

Parameters

data : array_like
Data to use in calculating the MLEs.

args : floats, optional
Starting value(s) for any shape-characterizing arguments (those not provided will be determined by a call to \_fitstart\(\text{data}\)). No default value.

**kwds** : floats, optional

Starting values for the location and scale parameters; no default. Special keyword arguments are recognized as holding certain parameters fixed:

- \(f0\ldots fn\) : hold respective shape parameters fixed. Alternatively, shape parameters to fix can be specified by name. For example, if self.shapes == "a, b", \(\text{fa} \) and \(\text{fix}_a\) are equivalent to \(f0\), and \(\text{fb}\) and \(\text{fix}_b\) are equivalent to \(f1\).
- \(floc\) : hold location parameter fixed to specified value.
- \(fscale\) : hold scale parameter fixed to specified value.
- \(\text{optimizer}\) : The optimizer to use. The optimizer must take \(\text{func}\), and starting position as the first two arguments, plus \(\text{args}\) (for extra arguments to pass to the function to be optimized) and \(\text{disp}=0\) to suppress output as keyword arguments.

**Returns**

\(\text{mle\_tuple}\) : tuple of floats

MLEs for any shape parameters (if applicable), followed by those for location and scale. For most random variables, shape statistics will be returned, but there are exceptions (e.g. \(\text{norm}\)).

**Notes**

This fit is computed by maximizing a log-likelihood function, with penalty applied for samples outside of range of the distribution. The returned answer is not guaranteed to be the globally optimal MLE, it may only be locally optimal, or the optimization may fail altogether.

**Examples**

Generate some data to fit: draw random variates from the \(\text{beta}\) distribution

```python
>>> from scipy.stats import beta
>>> a, b = 1., 2.
>>> x = beta.rvs(a, b, size=1000)
```

Now we can fit all four parameters (\(a, b, \text{loc}\) and \(\text{scale}\)):

```python
>>> a1, b1, loc1, scale1 = beta.fit(x)
```

We can also use some prior knowledge about the dataset: let’s keep \(\text{loc}\) and \(\text{scale}\) fixed:

```python
>>> a1, b1, loc1, scale1 = beta.fit(x, floc=0, fscale=1)
>>> loc1, scale1
(0, 1)
```

We can also keep shape parameters fixed by using \(f\)-keywords. To keep the zero-th shape parameter \(a\) equal \(1\), use \(f0=1\) or, equivalently, \(fa=1\):

```python
>>> a1, b1, loc1, scale1 = beta.fit(x, fa=1, floc=0, fscale=1)
>>> a1
1
```

Not all distributions return estimates for the shape parameters. \(\text{norm}\) for example just returns estimates for location and scale:
```python
>>> from scipy.stats import norm

>>> x = norm.rvs(a, b, size=1000, random_state=123)

>>> loc1, scale1 = norm.fit(x)

>>> loc1, scale1
(0.92087172783841631, 2.0015750750324668)
```

```python
rv_continuous.fit_loc_scale(data, *args)

Estimate loc and scale parameters from data using 1st and 2nd moments.

Parameters

- **data**: array_like
  Data to fit.
- **arg1, arg2, arg3,**...  : array_like
  The shape parameter(s) for the distribution (see docstring of the instance object for more information).

Returns

- **Lhat**: float
  Estimated location parameter for the data.
- **Shat**: float
  Estimated scale parameter for the data.
```

```python
rv_continuous.nnlf(theta, x)

Return negative loglikelihood function.

Notes

This is \(-\sum(\log pdf(x, theta), axis=0)\) where \(theta\) are the parameters (including loc and scale).
```

```python
class scipy.stats.rv_discrete(a=0, b=inf, name=None, badvalue=None, moment_tol=1e-08, values=None, inc=1, longname=None, shapes=None, extradoc=None, seed=None)

A generic discrete random variable class meant for subclassing.
```

`rv_discrete` is a base class to construct specific distribution classes and instances for discrete random variables. It can also be used to construct an arbitrary distribution defined by a list of support points and corresponding probabilities.

Parameters

- **a**: float, optional
  Lower bound of the support of the distribution, default: 0
- **b**: float, optional
  Upper bound of the support of the distribution, default: plus infinity
- **moment_tol**: float, optional
  The tolerance for the generic calculation of moments.
- **values**: tuple of two array_like, optional
  \((xk, pk)\) where \(xk\) are integers with non-zero probabilities \(pk\) with \(\sum(pk) = 1\).
- **inc**: integer, optional
  Increment for the support of the distribution. Default is 1. (other values have not been tested)
- **badvalue**: float, optional
  The value in a result arrays that indicates a value that for which some argument restriction is violated, default is np.nan.
- **name**: str, optional
  The name of the instance. This string is used to construct the default example for distributions.
- **longname**: str, optional
  This string is used as part of the first line of the docstring returned when a subclass has no docstring of its own. Note: `longname` exists for backwards compatibility, do not use for new subclasses.
shapes : str, optional
The shape of the distribution. For example “m, n” for a distribution that takes two integers as the two shape arguments for all its methods. If not provided, shape parameters will be inferred from the signatures of the private methods, _pmf and _cdf of the instance.

extradoc : str, optional
This string is used as the last part of the docstring returned when a subclass has no docstring of its own. Note: extradoc exists for backwards compatibility, do not use for new subclasses.

seed : None or int or numpy.random.RandomState instance, optional
This parameter defines the RandomState object to use for drawing random variates. If None, the global np.random state is used. If integer, it is used to seed the local RandomState instance. Default is None.

Notes
This class is similar to rv_continuous. Whether a shape parameter is valid is decided by an _argcheck method (which defaults to checking that its arguments are strictly positive.) The main differences are:
- the support of the distribution is a set of integers
- instead of the probability density function, pdf (and the corresponding private _pdf), this class defines the probability mass function, pmf (and the corresponding private _pmf.)
- scale parameter is not defined.

To create a new discrete distribution, we would do the following:

```python
>>> from scipy.stats import rv_discrete
>>> class poisson_gen(rv_discrete):
...     "Poisson distribution"
...     def _pmf(self, k, mu):
...         return exp(-mu) * mu**k / factorial(k)
```

and create an instance:

```python
>>> poisson = poisson_gen(name="poisson")
```

Note that above we defined the Poisson distribution in the standard form. Shifting the distribution can be done by providing the loc parameter to the methods of the instance. For example, poisson.pmf(x, mu, loc) delegates the work to poisson._pmf(x-loc, mu).

Discrete distributions from a list of probabilities
Alternatively, you can construct an arbitrary discrete rv defined on a finite set of values xk with Prob(X=xk) = pk by using the values keyword argument to the rv_discrete constructor.

Examples
Custom made discrete distribution:

```python
>>> from scipy import stats
>>> xk = np.arange(7)
>>> pk = (0.1, 0.2, 0.3, 0.1, 0.1, 0.0, 0.2)
>>> custm = stats.rv_discrete(name='custm', values=(xk, pk))
```

Random number generation:

```python
>>> R = custm.rvs(size=100)
```

**Attributes**

`random_state`  
Get or set the RandomState object for generating random variates.

`rv_discrete.random_state`  
Get or set the RandomState object for generating random variates.  
This can be either None or an existing RandomState object.  
If None (or np.random), use the RandomState singleton used by np.random.  If already a RandomState instance, use it.  If an int, use a new RandomState instance seeded with seed.

**Methods**

- `rvs(*args, **kwargs)`  
  Random variates of given type.
- `pmf(k, *args, **kwds)`  
  Probability mass function at k of the given RV.
- `logpmf(k, *args, **kwds)`  
  Log of the probability mass function at k of the given RV.
- `cdf(k, *args, **kwds)`  
  Cumulative distribution function of the given RV.
- `logcdf(k, *args, **kwds)`  
  Log of the cumulative distribution function at k of the given RV.
- `sf(k, *args, **kwds)`  
  Survival function (1 - cdf) at k of the given RV.
- `logsf(k, *args, **kwds)`  
  Log of the survival function of the given RV.
- `ppf(q, *args, **kwds)`  
  Percent point function (inverse of cdf) at q of the given RV.
- `isf(q, *args, **kwds)`  
  Inverse survival function (inverse of sf) at q of the given RV.
- `moment(n, *args, **kwds)`  
  n-th order non-central moment of distribution.
- `stats(*args, **kwds)`  
  Some statistics of the given RV.

**rv_discrete.rvs(*args, **kwargs)**
Random variates of given type.

**Parameters**
- arg1, arg2, arg3,... : array_like
  The shape parameter(s) for the distribution (see docstring of the instance object for more information).
- loc : array_like, optional
  Location parameter (default=0).
- size : int or tuple of ints, optional
  Defining number of random variates (Default is 1). Note that size has to be given as keyword, not as positional argument.
- random_state : None or int or np.random.RandomState instance, optional
  If int or RandomState, use it for drawing the random variates. If None, rely on self.random_state. Default is None.

**Returns**
- rvs : ndarray or scalar
  Random variates of given size.

**rv_discrete.pmf(k, *args, **kwargs)**
Probability mass function at k of the given RV.

**Parameters**
- k : array_like
  Quantiles.
- arg1, arg2, arg3,... : array_like
  The shape parameter(s) for the distribution (see docstring of the instance object for more information).
- loc : array_like, optional
  Location parameter (default=0).

**Returns**
- pmf : array_like
  Probability mass function evaluated at k.

**rv_discrete.logpmf(k, *args, **kwargs)**
Log of the probability mass function at k of the given RV.

**Parameters**
- k : array_like
  Quantiles.
- arg1, arg2, arg3,... : array_like
  The shape parameter(s) for the distribution (see docstring of the instance object for more information).
- loc : array_like, optional
  Location parameter. Default is 0.

**Returns**
- logpmf : array_like
  Log of the probability mass function evaluated at k.

**rv_discrete.cdf(k, *args, **kwargs)**
Cumulative distribution function of the given RV.

**Parameters**
- k : array_like, int
Quantiles.

arg1, arg2, arg3,... : array_like
    The shape parameter(s) for the distribution (see docstring of the instance object for more information).
loc : array_like, optional

Returns
cdf : ndarray
    Location parameter (default=0).

Cumulative distribution function evaluated at k.

rv_discrete.logcdf(k, *args, **kwds)
Log of the cumulative distribution function at k of the given RV.

Parameters
k : array_like, int
    Quantiles.
arg1, arg2, arg3,... : array_like
    The shape parameter(s) for the distribution (see docstring of the instance object for more information).
loc : array_like, optional

Returns
logcdf : array_like
    Location parameter (default=0).

Log of the cumulative distribution function evaluated at k.

rv_discrete.sf(k, *args, **kwds)
Survival function (1 - cdf) at k of the given RV.

Parameters
k : array_like
    Quantiles.
arg1, arg2, arg3,... : array_like
    The shape parameter(s) for the distribution (see docstring of the instance object for more information).
loc : array_like, optional

Returns
sf : array_like
    Location parameter (default=0).

Survival function evaluated at k.

rv_discrete.logsf(k, *args, **kwds)
Log of the survival function of the given RV.

Returns the log of the “survival function,” defined as 1 - cdf, evaluated at k.

Parameters
k : array_like
    Quantiles.
arg1, arg2, arg3,... : array_like
    The shape parameter(s) for the distribution (see docstring of the instance object for more information).
loc : array_like, optional

Returns
logsf : ndarray
    Location parameter (default=0).

Log of the survival function evaluated at k.

rv_discrete.ppf(q, *args, **kwds)
Percent point function (inverse of cdf) at q of the given RV.

Parameters
q : array_like
    Lower tail probability.
arg1, arg2, arg3,... : array_like
    The shape parameter(s) for the distribution (see docstring of the instance object for more information).
loc : array_like, optional

Returns
k : array_like
    Location parameter (default=0).
Quantile corresponding to the lower tail probability, q.

\texttt{rv\_discrete.isf}(q, *args, **kwds)

Inverse survival function (inverse of \texttt{sf}) at q of the given RV.

**Parameters**

- \texttt{q} : array_like
  Upper tail probability.
- \texttt{arg1, arg2, arg3,\ldots} : array_like
  The shape parameter(s) for the distribution (see docstring of the instance object for more information).
- \texttt{loc} : array_like, optional
  Location parameter (default=0).

**Returns**

- \texttt{k} : ndarray or scalar
  Quantile corresponding to the upper tail probability, q.

\texttt{rv\_discrete.moment}(n, *args, **kwds)

n-th order non-central moment of distribution.

**Parameters**

- \texttt{n} : int, n >= 1
  Order of moment.
- \texttt{arg1, arg2, arg3,\ldots} : float
  The shape parameter(s) for the distribution (see docstring of the instance object for more information).
- \texttt{loc} : array_like, optional
  Location parameter (default=0)
- \texttt{scale} : array_like, optional
  Scale parameter (default=1)

\texttt{rv\_discrete.stats}(*args, **kwds)

Some statistics of the given RV.

**Parameters**

- \texttt{arg1, arg2, arg3,\ldots} : array_like
  The shape parameter(s) for the distribution (see docstring of the instance object for more information)
- \texttt{loc} : array_like, optional
  Location parameter (default=0)
- \texttt{scale} : array_like, optional (continuous RVs only)
  Scale parameter (default=1)
- \texttt{moments} : str, optional
  composed of letters ['mvsk'] defining which moments to compute: 'm' = mean, 'v' = variance, 's' = (Fisher’s) skew, ‘k’ = (Fisher’s) kurtosis. (default is ‘mv’)

**Returns**

- \texttt{stats} : sequence
  of requested moments.

\texttt{rv\_discrete.entropy}(*args, **kwds)

Differential entropy of the RV.

**Parameters**

- \texttt{arg1, arg2, arg3,\ldots} : array_like
  The shape parameter(s) for the distribution (see docstring of the instance object for more information).
- \texttt{loc} : array_like, optional
  Location parameter (default=0).
- \texttt{scale} : array_like, optional (continuous distributions only).
  Scale parameter (default=1).
Notes

Entropy is defined base $e$:

```python
>>> drv = rv_discrete(values=((0, 1), (0.5, 0.5)))
>>> np.allclose(drv.entropy(), np.log(2.0))
True
```

`rv_discrete.expect` *(func=None, args=(), loc=0, lb=None, ub=None, conditional=False, maxcount=1000, tolerance=1e-10, chunksize=32)*

Calculate expected value of a function with respect to the distribution for discrete distribution.

**Parameters**

- **func**: callable, optional
  Function for which the expectation value is calculated. Takes only one argument. The default is the identity mapping $f(k) = k$.
- **args** : tuple, optional
  Shape parameters of the distribution.
- **loc** : float, optional
  Location parameter. Default is 0.
- **lb, ub** : int, optional
  Lower and upper bound for the summation, default is set to the support of the distribution, inclusive ($ul \leq k \leq ub$).
- **conditional** : bool, optional
  If true then the expectation is corrected by the conditional probability of the summation interval. The return value is the expectation of the function, `func`, conditional on being in the given interval ($k$ such that $ul \leq k \leq ub$). Default is False.
- **maxcount** : int, optional
  Maximal number of terms to evaluate (to avoid an endless loop for an infinite sum). Default is 1000.
- **tolerance** : float, optional
  Absolute tolerance for the summation. Default is 1e-10.
- **chunksize** : int, optional
  Iterate over the support of a distributions in chunks of this size. Default is 32.

**Returns**

- **expect** : float
  Expected value.

Notes

For heavy-tailed distributions, the expected value may or may not exist, depending on the function, `func`. If it does exist, but the sum converges slowly, the accuracy of the result may be rather low. For instance, for `zipf(4)`, accuracy for mean, variance in example is only 1e-5. Increasing `maxcount` and/or `chunksize` may improve the result, but may also make `zipf` very slow.

The function is not vectorized.

`rv_discrete.median` *(args, **kwds)*

Median of the distribution.

**Parameters**

- **arg1, arg2, arg3**, ... : array_like
  The shape parameter(s) for the distribution (see docstring of the instance object for more information)
- **loc** : array_like, optional
  Location parameter, Default is 0.
- **scale** : array_like, optional
  Scale parameter, Default is 1.

**Returns**

- **median** : float
  The median of the distribution.
See also:

```
stats.distributions.rv_discrete.ppf
```
Inverse of the CDF

```
rv_discrete.mean(*args, **kwds)
```
Mean of the distribution.

**Parameters**

arg1, arg2, arg3,... : array_like
The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc : array_like, optional
location parameter (default=0)

scale : array_like, optional
scale parameter (default=1)

**Returns**

mean : float
the mean of the distribution

```
rv_discrete.std(*args, **kwds)
```
Standard deviation of the distribution.

**Parameters**

arg1, arg2, arg3,... : array_like
The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc : array_like, optional
location parameter (default=0)

scale : array_like, optional
scale parameter (default=1)

**Returns**

std : float
standard deviation of the distribution

```
rv_discrete.var(*args, **kwds)
```
Variance of the distribution.

**Parameters**

arg1, arg2, arg3,... : array_like
The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc : array_like, optional
location parameter, Default is 0.

scale : array_like, optional
scale parameter, Default is 1.

**Returns**

var : float
the variance of the distribution

```
rv_discrete.interval(alpha, *args, **kwds)
```
Confidence interval with equal areas around the median.

**Parameters**

alpha : array_like of float
Probability that an rv will be drawn from the returned range. Each value should be in the range [0, 1].

arg1, arg2, ... : array_like
The shape parameter(s) for the distribution (see docstring of the instance object for more information).

loc : array_like, optional
location parameter, Default is 0.

scale : array_like, optional
scale parameter, Default is 1.

**Returns**

a, b : ndarray of float
end-points of range that contain 100 * alpha % of the rv’s possible values.
rv_discrete.__call__(*args, **kwds)
Freeze the distribution for the given arguments.

Parameters:  
arg1, arg2, arg3,... : array_like
The shape parameter(s) for the distribution. Should include all the
non-optional arguments, may include loc and scale.

Returns:  
rv_frozen : rv_frozen instance
The frozen distribution.

class scipy.stats.rv_histogram(histogram, *args, **kwargs)
Generates a distribution given by a histogram. This is useful to generate a template distribution from a binned
datasample.

As a subclass of the rv_continuous class, rv_histogram inherits from it a collection of generic methods
(see rv_continuous for the full list), and implements them based on the properties of the provided binned
datasample.

Parameters: histogram : tuple of array_like
Tuple containing two array_like objects The first containing the content of n
bins The second containing the (n+1) bin boundaries In particular the return
value np.histogram is accepted

Notes
There are no additional shape parameters except for the loc and scale. The pdf is defined as a stepwise function
from the provided histogram The cdf is a linear interpolation of the pdf.
New in version 0.19.0.

Examples
Create a scipy.stats distribution from a numpy histogram

```python
>>> import scipy.stats
>>> import numpy as np
>>> data = scipy.stats.norm.rvs(size=100000, loc=0, scale=1.5, random_state=123)
>>> hist = np.histogram(data, bins=100)
>>> hist_dist = scipy.stats.rv_histogram(hist)
```

Behaves like an ordinary scipy rv_continuous distribution

```python
>>> hist_dist.pdf(1.0)
0.20538577847618705
>>> hist_dist.cdf(2.0)
0.90818568543056499
```

PDF is zero above (below) the highest (lowest) bin of the histogram, defined by the max (min) of the original
dataset

```python
>>> hist_dist.pdf(np.max(data))
0.0
>>> hist_dist.cdf(np.max(data))
1.0
>>> hist_dist.pdf(np.min(data))
7.759190724498314e-05
>>> hist_dist.cdf(np.min(data))
0.0
```

PDF and CDF follow the histogram
>>> import matplotlib.pyplot as plt
>>> X = np.linspace(-5.0, 5.0, 100)
>>> plt.title("PDF from Template")
>>> plt.hist(data, normed=True, bins=100)
>>> plt.plot(X, hist_dist.pdf(X), label='PDF')
>>> plt.plot(X, hist_dist.cdf(X), label='CDF')
>>> plt.show()

PDF from Template

Attributes

random_state

Get or set the RandomState object for generating random variates.

rv_histogram.random_state

Get or set the RandomState object for generating random variates.

This can be either None or an existing RandomState object.

If None (or np.random), use the RandomState singleton used by np.random. If already a RandomState instance, use it. If an int, use a new RandomState instance seeded with seed.

Methods

__call__(*args, **kwds)

Freeze the distribution for the given arguments.

cdf(x, *args, **kwds)

Cumulative distribution function of the given RV.

entropy(*args, **kwds)

Differential entropy of the RV.

expect(func, args, loc, scale, lb, ub, ...)

Calculate expected value of a function with respect to the distribution.

fit(data, *args, **kwds)

Return MLEs for shape (if applicable), location, and scale parameters from data.

fit_loc_scale(data, *args)

Estimate loc and scale parameters from data using 1st and 2nd moments.

freeze(*args, **kwds)

Freeze the distribution for the given arguments.

interval(alpha, *args, **kwds)

Confidence interval with equal areas around the median.

</table>

`rv_histogram.__call__(*args, **kwds)`

Freeze the distribution for the given arguments.

**Parameters**  
`arg1, arg2, arg3, ...` : array_like  
The shape parameter(s) for the distribution. Should include all the non-optional arguments, may include `loc` and `scale`.

**Returns**  
`rv_frozen` : rv_frozen instance  
The frozen distribution.

`rv_histogram.cdf(x, *args, **kwds)`

Cumulative distribution function of the given RV.

**Parameters**  
x : array_like  
quantiles of the distribution

`arg1, arg2, arg3, ...` : array_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information)

`loc` : array_like, optional  
location parameter (default=0)

`scale` : array_like, optional  
scale parameter (default=1)

**Returns**  
`cdf` : ndarray  
Cumulative distribution function evaluated at x

`rv_histogram.entropy(*args, **kwds)`

Differential entropy of the RV.

**Parameters**  
`arg1, arg2, arg3, ...` : array_like  
The shape parameter(s) for the distribution (see docstring of the instance object for more information).

`loc` : array_like, optional  
Location parameter (default=0).

`scale` : array_like, optional  
Scale parameter (default=1).
Notes

Entropy is defined base e:

```python
>>> drv = rv_discrete(values=((0, 1), (0.5, 0.5)))
>>> np.allclose(drv.entropy(), np.log(2.0))
True
```

`rv_histogram.expect` *(func=None, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)*

Calculate expected value of a function with respect to the distribution.

The expected value of a function \( f(x) \) with respect to a distribution \( \text{dist} \) is defined as:

\[
\begin{align*}
\text{ubound} & \quad \mathbb{E}[x] = \int f(x) \times \text{dist.pdf}(x) \\
\text{lbound}
\end{align*}
\]

Parameters

- **func**: callable, optional
  
  Function for which integral is calculated. Takes only one argument.
  
  The default is the identity mapping \( f(x) = x \).

- **args**: tuple, optional
  
  Shape parameters of the distribution.

- **loc**: float, optional
  
  Location parameter (default=0).

- **scale**: float, optional
  
  Scale parameter (default=1).

- **lb, ub**: scalar, optional
  
  Lower and upper bound for integration. Default is set to the support of the distribution.

- **conditional**: bool, optional
  
  If True, the integral is corrected by the conditional probability of the integration interval. The return value is the expectation of the function, conditional on being in the given interval. Default is False.

Returns

- **expect**: float
  
  The calculated expected value.

Notes

The integration behavior of this function is inherited from `integrate.quad`.

`rv_histogram.fit` *(data, *args, **kwds)*

Return MLEs for shape (if applicable), location, and scale parameters from data.

MLE stands for Maximum Likelihood Estimate. Starting estimates for the fit are given by input arguments; for any arguments not provided with starting estimates, `self._fitstart(data)` is called to generate such.

One can hold some parameters fixed to specific values by passing in keyword arguments `f0, f1, ..., fn` (for shape parameters) and `floc` and `fscale` (for location and scale parameters, respectively).

Parameters

- **data**: array_like
  
  Data to use in calculating the MLEs.

- **args**: floats, optional
  
  Starting value(s) for any shape-characterizing arguments (those not provided will be determined by a call to `_fitstart(data)`). No default value.

- **kwds**: floats, optional
Starting values for the location and scale parameters; no default. Special keyword arguments are recognized as holding certain parameters fixed:

- `f0...fn`: hold respective shape parameters fixed. Alternatively, shape parameters to fix can be specified by name. For example, if `self.shapes == "a, b"`, `fa` and `fix_a` are equivalent to `f0` and `fb` and `fix_b` are equivalent to `f1`.
- `floc`: hold location parameter fixed to specified value.
- `fscale`: hold scale parameter fixed to specified value.
- `optimizer`: the optimizer to use. The optimizer must take `func` and starting position as the first two arguments, plus `args` (for extra arguments to pass to the function to be optimized) and `disp=0` to suppress output as keyword arguments.

Returns `mle_tuple`: tuple of floats

MLEs for any shape parameters (if applicable), followed by those for location and scale. For most random variables, shape statistics will be returned, but there are exceptions (e.g. `norm`).

Notes

This fit is computed by maximizing a log-likelihood function, with penalty applied for samples outside of range of the distribution. The returned answer is not guaranteed to be the globally optimal MLE, it may only be locally optimal, or the optimization may fail altogether.

Examples

Generate some data to fit: draw random variates from the beta distribution

```python
>>> from scipy.stats import beta
>>> a, b = 1., 2.
>>> x = beta.rvs(a, b, size=1000)
```

Now we can fit all four parameters (`a`, `b`, `loc` and `scale`):

```python
>>> al, bl, loc1, scale1 = beta.fit(x)
```

We can also use some prior knowledge about the dataset: let’s keep `loc` and `scale` fixed:

```python
>>> al, bl, loc1, scale1 = beta.fit(x, floc=0, fscale=1)
>>> loc1, scale1
(0.0, 1.0)
```

We can also keep shape parameters fixed by using `f`-keywords. To keep the zero-th shape parameter `a` equal 1, use `f0=1` or, equivalently, `fa=1`:

```python
>>> al, bl, loc1, scale1 = beta.fit(x, fa=1, floc=0, fscale=1)
>>> al
1.0
```

Not all distributions return estimates for the shape parameters. `norm`, for example, just returns estimates for location and scale:

```python
>>> from scipy.stats import norm
>>> x = norm.rvs(a, b, size=1000, random_state=123)
>>> loc1, scale1 = norm.fit(x)
>>> loc1, scale1
(0.92087172783841631, 2.0015750750324668)
```
rv_histogram.fit_loc_scale(data, *args)
Estimate loc and scale parameters from data using 1st and 2nd moments.

Parameters
- data: array_like
  Data to fit.
- arg1, arg2, arg3,...: array_like
  The shape parameter(s) for the distribution (see docstring of the instance object for more information).

Returns
- Lhat: float
  Estimated location parameter for the data.
- Shat: float
  Estimated scale parameter for the data.

data
rv_histogram.freeze(*args, **kwds)
Freeze the distribution for the given arguments.

Parameters
- arg1, arg2, arg3,...: array_like
  The shape parameter(s) for the distribution. Should include all the non-optional arguments, may include loc and scale.

Returns
- rv_frozen: rv_frozen instance
  The frozen distribution.

data
rv_histogram.interval(alpha, *args, **kwds)
Confidence interval with equal areas around the median.

Parameters
- alpha: array_like of float
  Probability that an rv will be drawn from the returned range. Each value should be in the range [0, 1].
- arg1, arg2, ...: array_like
  The shape parameter(s) for the distribution (see docstring of the instance object for more information).
- loc: array_like, optional
  location parameter, Default is 0.
- scale: array_like, optional
  scale parameter, Default is 1.

Returns
- a, b: ndarray of float
  end-points of range that contain 100 * alpha % of the rv’s possible values.

data
rv_histogram.isf(q, *args, **kwds)
Inverse survival function (inverse of sf) at q of the given RV.

Parameters
- q: array_like
  upper tail probability
- arg1, arg2, arg3,...: array_like
  The shape parameter(s) for the distribution (see docstring of the instance object for more information)
- loc: array_like, optional
  location parameter (default=0)
- scale: array_like, optional
  scale parameter (default=1)

Returns
- x: ndarray or scalar
  Quantile corresponding to the upper tail probability q.

data
rv_histogram.logcdf(x, *args, **kwds)
Log of the cumulative distribution function at x of the given RV.

Parameters
- x: array_like
  quantiles
- arg1, arg2, arg3,...: array_like
The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** : array_like, optional
location parameter (default=0)

**scale** : array_like, optional
scale parameter (default=1)

**Returns**

- **logcdf** : array_like
  Log of the cumulative distribution function evaluated at x

```
rv_histogram.logpdf(x, *args, **kwds)
```

Log of the probability density function at x of the given RV.

This uses a more numerically accurate calculation if available.

**Parameters**

- **x** : array_like
  quantiles
- **arg1, arg2, arg3,...** : array_like
  The shape parameter(s) for the distribution (see docstring of the instance object for more information)
- **loc** : array_like, optional
  location parameter (default=0)
- **scale** : array_like, optional
  scale parameter (default=1)

**Returns**

- **logpdf** : array_like
  Log of the probability density function evaluated at x

```
rv_histogram.logsf(x, *args, **kwds)
```

Log of the survival function of the given RV.

Returns the log of the “survival function,” defined as \(1 - \text{cdf}\), evaluated at x.

**Parameters**

- **x** : array_like
  quantiles
- **arg1, arg2, arg3,...** : array_like
  The shape parameter(s) for the distribution (see docstring of the instance object for more information)
- **loc** : array_like, optional
  location parameter (default=0)
- **scale** : array_like, optional
  scale parameter (default=1)

**Returns**

- **logsf** : ndarray
  Log of the survival function evaluated at x

```
rv_histogram.mean(*args, **kwds)
```

Mean of the distribution.

**Parameters**

- **arg1, arg2, arg3,...** : array_like
  The shape parameter(s) for the distribution (see docstring of the instance object for more information)
- **loc** : array_like, optional
  location parameter (default=0)
- **scale** : array_like, optional
  scale parameter (default=1)

**Returns**

- **mean** : float
  the mean of the distribution

```
v_histogram.median(*args, **kwds)
```

Median of the distribution.

**Parameters**

- **arg1, arg2, arg3,...** : array_like
The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc : array_like, optional
    Location parameter, Default is 0.
scale : array_like, optional
    Scale parameter, Default is 1.

Returns
median : float
The median of the distribution.

See also:

stats.distributions.rv_discrete.ppf
Inverse of the CDF

rv_histogram.moment(n, *args, **kwds)
n-th order non-central moment of distribution.

Parameters
n : int, n >= 1
    Order of moment.
arg1, arg2, arg3,... : float
    The shape parameter(s) for the distribution (see docstring of the instance object for more information).
loc : array_like, optional
    location parameter (default=0)
scale : array_like, optional
    scale parameter (default=1)

rv_histogram.nnlf(theta, x)
Return negative loglikelihood function.

Notes
This is -sum(log pdf(x, theta), axis=0) where theta are the parameters (including loc and scale).

rv_histogram.pdf(x, *args, **kwds)
Probability density function at x of the given RV.

Parameters
x : array_like
    quantiles
arg1, arg2, arg3,... : array_like
    The shape parameter(s) for the distribution (see docstring of the instance object for more information)
loc : array_like, optional
    location parameter (default=0)
scale : array_like, optional
    scale parameter (default=1)

Returns
pdf : ndarray
    Probability density function evaluated at x

rv_histogram.ppf(q, *args, **kwds)
Percent point function (inverse of cdf) at q of the given RV.

Parameters
q : array_like
    lower tail probability
arg1, arg2, arg3,... : array_like
    The shape parameter(s) for the distribution (see docstring of the instance object for more information)
loc : array_like, optional
    location parameter (default=0)
scale : array_like, optional

Returns : x : array_like
quantile corresponding to the lower tail probability q.

rv_histogram.rvs(*args, **kwds)
Random variates of given type.

Parameters arg1, arg2, arg3,... : array_like
    The shape parameter(s) for the distribution (see docstring of the inst-
    ance object for more information).
loc : array_like, optional
    Location parameter (default=0).
scale : array_like, optional
    Scale parameter (default=1).
size : int or tuple of ints, optional
    Defining number of random variates (default is 1).
random_state : None or int or np.random.RandomState instance, optional
    If int or RandomState, use it for drawing the random variates. If
    None, rely on self.random_state. Default is None.

Returns rvs : ndarray or scalar
Random variates of given size.

rv_histogram.sf(x, *args, **kwds)
Survival function (1 - cdf) at x of the given RV.

Parameters x : array_like
    quantiles
arg1, arg2, arg3,... : array_like
    The shape parameter(s) for the distribution (see docstring of the inst-
    ance object for more information)
loc : array_like, optional
    location parameter (default=0)
scale : array_like, optional
    scale parameter (default=1)

Returns sf : array_like
    Survival function evaluated at x

rv_histogram.stats(*args, **kwds)
Some statistics of the given RV.

Parameters arg1, arg2, arg3,... : array_like
    The shape parameter(s) for the distribution (see docstring of the inst-
    ance object for more information)
loc : array_like, optional
    location parameter (default=0)
scale : array_like, optional (continuous RVs only)
    scale parameter (default=1)
moments : str, optional
    composed of letters ['mvsk'] defining which moments to compute:
    'm' = mean, 'v' = variance, 's' = (Fisher's) skew, 'k' = (Fisher's)
    kurtosis. (default is 'mv')

Returns stats : sequence
    of requested moments.

rv_histogram.std(*args, **kwds)
Standard deviation of the distribution.

Parameters arg1, arg2, arg3,... : array_like
The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc**: array_like, optional
Location parameter (default=0)

**scale**: array_like, optional
Scale parameter (default=1)

**Returns**

**std**: float
Standard deviation of the distribution

```python
rv_histogram.var(*args, **kwds)
```
Variance of the distribution.

**Parameters**

*arg1, arg2, arg3, ...*: array_like
The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc**: array_like, optional
Location parameter (default=0)

**scale**: array_like, optional
Scale parameter (default=1)

**Returns**

**var**: float
The variance of the distribution

scipy.stats.alpha = <scipy.stats._continuous_distns.alpha_gen object>

An alpha continuous random variable.

As an instance of the rv_continuous class, alpha object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for alpha is:

\[
f(x, a) = \frac{1}{x^2 \Phi(a)\sqrt{2\pi}} \exp\left(-\frac{1}{2}(a - 1/x)^2\right)
\]

where \(\Phi(a)\) is the normal CDF, \(x > 0\), and \(a > 0\).

alpha takes \(a\) as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, alpha.pdf\((x, a, \text{loc}, \text{scale})\) is identically equivalent to alpha.pdf\((y, a) / \text{scale} with y = (x - \text{loc}) / \text{scale}\).

Examples

```python
>>> from scipy.stats import alpha
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> a = 3.57
>>> mean, var, skew, kurt = alpha.stats(a, moments='mvsk')
```
Display the probability density function (pdf):

```python
>>> x = np.linspace(alpha.ppf(0.01, a),
                    alpha.ppf(0.99, a), 100)
>>> ax.plot(x, alpha.pdf(x, a),
          'r-', lw=5, alpha=0.6, label='alpha pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = alpha(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = alpha.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], alpha.cdf(vals, a))
True
```

Generate random numbers:

```python
>>> r = alpha.rvs(a, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.anglit = <scipy.stats._continuous_distns.anglit_gen object>
An anglit continuous random variable.

As an instance of the rv_continuous class, anglit object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for anglit is:

\[ f(x) = \sin(2x + \pi/2) = \cos(2x) \]

for \(-\pi/4 \leq x \leq \pi/4\).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, anglit.pdf(x, loc, scale) is identically equivalent to anglit.pdf(y) / scale with y = (x - loc) / scale.

Examples

```python
>>> from scipy.stats import anglit
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:
>>> mean, var, skew, kurt = anglit.stats(moments='mvsk')

Display the probability density function (pdf):

```python
>>> x = np.linspace(anglit.ppf(0.01),
...                   anglit.ppf(0.99), 100)
>>> ax.plot(x, anglit.pdf(x),
...         'r-', lw=5, alpha=0.6, label='anglit pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = anglit()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = anglit.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], anglit.cdf(vals))
True
```

Generate random numbers:

```python
>>> r = anglit.rvs(size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```
Methods

- `rvs(loc=0, scale=1, size=1, random_state=None)`: Random variates.
- `pdf(x, loc=0, scale=1)`: Probability density function.
- `logpdf(x, loc=0, scale=1)`: Log of the probability density function.
- `cdf(x, loc=0, scale=1)`: Cumulative distribution function.
- `logcdf(x, loc=0, scale=1)`: Log of the cumulative distribution function.
- `sf(x, loc=0, scale=1)`: Survival function (also defined as $1 - \text{cdf}$, but $sf$ is sometimes more accurate).
- `logsf(x, loc=0, scale=1)`: Log of the survival function.
- `ppf(q, loc=0, scale=1)`: Percent point function (inverse of $\text{cdf}$ — percentiles).
- `isf(q, loc=0, scale=1)`: Inverse survival function (inverse of $sf$).
- `moment(n, loc=0, scale=1)`: Non-central moment of order $n$.
- `stats(loc=0, scale=1, moments='mv')`: Mean(‘m’), variance(‘v’), skew(‘s’), and/or kurtosis(‘k’).
- `entropy(loc=0, scale=1)`: (Differential) entropy of the RV.
- `fit(data, loc=0, scale=1)`: Parameter estimates for generic data.
- `expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)`: Expected value of a function (of one argument) with respect to the distribution.
- `median(loc=0, scale=1)`: Median of the distribution.
- `mean(loc=0, scale=1)`: Mean of the distribution.
- `var(loc=0, scale=1)`: Variance of the distribution.
- `std(loc=0, scale=1)`: Standard deviation of the distribution.
- `interval(alpha, loc=0, scale=1)`: Endpoints of the range that contains alpha percent of the distribution

**scipy.stats.arcsine = <scipy.stats.continuous_distns.arcsine_gen object>**

An arcsine continuous random variable.

As an instance of the `rv_continuous` class, `arcsine` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `arcsine` is:

$$f(x) = \frac{1}{\pi \sqrt{x(1-x)}}$$

for $0 \leq x \leq 1$.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `arcsine.pdf(x, loc, scale)` is identically equivalent to `arcsine.pdf(y) / scale` with $y = (x - loc) / scale$.

**Examples**

```python
>>> from scipy.stats import arcsine
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:
>>> mean, var, skew, kurt = arcsine.stats(moments='mvsk')

Display the probability density function (pdf):

```python
>>> x = np.linspace(arcsine.ppf(0.01),
...     arcsine.ppf(0.99), 100)
>>> ax.plot(x, arcsine.pdf(x),
...     'r-', lw=5, alpha=0.6, label='arcsine pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = arcsine()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = arcsine.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], arcsine.cdf(vals))
True
```

Generate random numbers:

```python
>>> r = arcsine.rvs(size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.argus = <scipy.stats._continuous_distns.argus_gen object>

Argus distribution

As an instance of the `rv_continuous` class, `argus` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `argus` is:

\[
f(x, \chi) = \frac{\chi^3}{\sqrt{2\pi} \Psi(\chi)} x \sqrt{1 - x^2} \exp(-0.5 \chi^2 (1 - x^2))
\]

where:

\[
\Psi(\chi) = \Phi(\chi) - \chi \phi(\chi) - 1/2
\]

with \( \Phi \) and \( \phi \) being the CDF and PDF of a standard normal distribution, respectively.

`argus` takes \( \chi \) as shape a parameter.

References

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `argus.pdf(x, chi, loc, scale)` is identically equivalent to `argus.pdf(y, chi) / scale with y = (x - loc) / scale`.

New in version 0.19.0.

[R609]
Examples

```python
>>> from scipy.stats import argus
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> chi = 1
>>> mean, var, skew, kurt = argus.stats(chi, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(argus.ppf(0.01, chi),
...                 argus.ppf(0.99, chi), 100)
>>> ax.plot(x, argus.pdf(x, chi),
...          'r-', lw=5, alpha=0.6, label='argus pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = argus(chi)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = argus.ppf([0.001, 0.5, 0.999], chi)
>>> np.allclose([0.001, 0.5, 0.999], argus.cdf(vals, chi))
```

Generate random numbers:

```python
>>> r = argus.rvs(chi, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.beta = <scipy.stats._continuous_distns.beta_gen object>

A beta continuous random variable.

As an instance of the `rv_continuous` class, `beta` object inherits from it a collection of generic methods.
(see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for $\text{beta}$ is:

$$f(x, a, b) = \frac{\gamma(a + b)x^{a-1}(1-x)^{b-1}}{\gamma(a)\gamma(b)}$$

for $0 < x < 1$, $a > 0$, $b > 0$, where $\gamma(z)$ is the gamma function ($\text{scipy.special.gamma}$).

$\text{beta}$ takes $a$ and $b$ as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the $\text{loc}$ and $\text{scale}$ parameters. Specifically, $\text{beta.pdf}(x, a, b, \text{loc}, \text{scale})$ is identically equivalent to $\text{beta.pdf}(y, a, b) / \text{scale}$ with $y = (x - \text{loc}) / \text{scale}$.

**Examples**

```python
>>> from scipy.stats import beta
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> a, b = 2.31, 0.627
>>> mean, var, skew, kurt = beta.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(beta.ppf(0.01, a, b),
...                 beta.ppf(0.99, a, b), 100)
>>> ax.plot(x, beta.pdf(x, a, b),
...         r'--', lw=5, alpha=0.6, label='beta pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = beta(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = beta.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], beta.cdf(vals, a, b))
```

Generate random numbers:

```python
>>> r = beta.rvs(a, b, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.betaprime = <scipy.stats._continuous_distns.betaprime_gen object>`

A beta prime continuous random variable.

As an instance of the `rv_continuous` class, `betaprime` object inherits from it a collection of generic
The probability density function for \textit{betaprime} is:

\[ f(x, a, b) = \frac{x^{a-1}(1 + x)^{-a-b}}{\beta(a, b)} \]

for \(x > 0, a > 0, b > 0\), where \(\beta(a, b)\) is the beta function (see \texttt{scipy.special.beta}). \textit{betaprime} takes \(a\) and \(b\) as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \texttt{loc} and \texttt{scale} parameters. Specifically, \texttt{betaprime.pdf(x, a, b, loc, scale)} is identically equivalent to \texttt{betaprime.pdf(y, a, b) / scale} with \(y = (x - \texttt{loc}) / \texttt{scale}\).

**Examples**

```python
>>> from scipy.stats import betaprime
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

>>> a, b = 5, 6
>>> mean, var, skew, kurt = betaprime.stats(a, b, moments='mvsk')

>>> x = np.linspace(betaprime.ppf(0.01, a, b),
...                   betaprime.ppf(0.99, a, b), 100)
>>> ax.plot(x, betaprime.pdf(x, a, b),
...         'r-', lw=5, alpha=0.6, label='betaprime pdf')

>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')

>>> vals = betaprime.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], betaprime.cdf(vals, a, b))

True
```

Generate random numbers:

```python
>>> r = betaprime.rvs(a, b, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

### scipy.stats.bradford

A Bradford continuous random variable.

As an instance of the `rv_continuous` class, `bradford` object inherits from it a collection of generic meth-
ods (see below for the full list), and completes them with details specific for this particular distribution.

Notes
The probability density function for *bradford* is:

\[ f(x, c) = \frac{c}{k(1 + cx)} \]

for \( 0 < x < 1, \ c > 0 \) and \( k = \log(1 + c) \).

*bradford* takes \( c \) as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, *bradford.pdf(x, c, loc, scale)* is identically equivalent to *bradford.pdf(y, c) / scale* with \( y = (x - \text{loc}) / \text{scale} \).

Examples

```python
>>> from scipy.stats import bradford
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> c = 0.299
>>> mean, var, skew, kurt = bradford.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(bradford.ppf(0.01, c),
...                 bradford.ppf(0.99, c), 100)
>>> ax.plot(x, bradford.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='bradford pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = bradford(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = bradford.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], bradford.cdf(vals, c))
```

Generate random numbers:

```python
>>> r = bradford.rvs(c, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

```python
scipy.stats.burr = scipy.stats._continuous_distns.burr_gen object
```

A Burr (Type III) continuous random variable.

As an instance of the `rv_continuous` class, `burr` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.
See also:

- **fisk**: a special case of either `burr` or `burr12` with `d = 1`
- **burr12**: Burr Type XII distribution

**Notes**

The probability density function for `burr` is:

\[
f(x, c, d) = cd x^{-c-1}(1 + x^{-c})^{-d-1}
\]

for \( x > 0 \).

`burr` takes \( c \) and \( d \) as shape parameters.

This is the PDF corresponding to the third CDF given in Burr’s list; specifically, it is equation (11) in Burr’s paper [R615].

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `burr.pdf(x, c, d, loc, scale)` is identically equivalent to `burr.pdf(y, c, d) / scale` with \( y = (x - \text{loc}) / \text{scale} \).

**References**

[R615]

**Examples**

```python
>>> from scipy.stats import burr
>>> import matplotlib.pyplot as plt

>>> c, d = 10.5, 4.3

>>> mean, var, skew, kurt = burr.stats(c, d, moments='mvsk')

>>> x = np.linspace(burr.ppf(0.01, c, d),
...                 burr.ppf(0.99, c, d), 100)

>>> ax.plot(x, burr.pdf(x, c, d),
...          'r-', lw=5, alpha=0.6, label='burr pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = burr(c, d)

>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = burr.ppf([0.001, 0.5, 0.999], c, d)

>>> np.allclose([0.001, 0.5, 0.999], burr.cdf(vals, c, d))

True
```

Generate random numbers:
```python
>>> r = burr.rvs(c, d, size=1000)

And compare the histogram:
```

scipy.stats.burr12 = <scipy.stats._continuous_distns.burr12_gen object>

A Burr (Type XII) continuous random variable.

As an instance of the rv_continuous class, burr12 object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:
- fisk a special case of either burr or burr12 with d = 1
- burr Burr Type III distribution

Notes

The probability density function for burr is:

\[ f(x, c, d) = cdx^{c-1}(1 + x^c)^{-d-1} \]

for \( x > 0 \).

burr12 takes \( c \) and \( d \) as shape parameters.

This is the PDF corresponding to the twelfth CDF given in Burr’s list; specifically, it is equation (20) in Burr’s paper [R616].

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, burr12.pdf(x, c, d, loc, scale) is identically equivalent to burr12.pdf(y, c, d) / scale with \( y = (x - \text{loc}) / \text{scale} \).
The Burr type 12 distribution is also sometimes referred to as the Singh-Maddala distribution from NIST [R617].

**References**

[R616], [R617]

**Examples**

```python
>>> from scipy.stats import burr12
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> c, d = 10, 4
>>> mean, var, skew, kurt = burr12.stats(c, d, moments='mvsk')
```  
Display the probability density function (pdf):

```python
>>> x = np.linspace(burr12.ppf(0.01, c, d),
...                 burr12.ppf(0.99, c, d), 100)
>>> ax.plot(x, burr12.pdf(x, c, d),
...         'r-', lw=5, alpha=0.6, label='burr12 pdf')
```  
Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = burr12(c, d)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```  
Check accuracy of cdf and ppf:

```python
>>> vals = burr12.ppf([0.001, 0.5, 0.999], c, d)
>>> np.allclose([0.001, 0.5, 0.999], burr12.cdf(vals, c, d))
True
```  
Generate random numbers:

```python
>>> r = burr12.rvs(c, d, size=1000)
```  
And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

```python
scipy.stats.cauchy = <scipy.stats._continuous_distns.cauchy_gen object>
```

A Cauchy continuous random variable.

As an instance of the `rv_continuous` class, `cauchy` object inherits from it a collection of generic methods.
The probability density function for `cauchy` is:

$$f(x) = \frac{1}{\pi(1 + x^2)}$$

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `cauchy.pdf(x, loc, scale)` is identically equivalent to `cauchy.pdf(y) / scale` with $y = (x - loc) / scale$.

**Examples**

```python
>>> from scipy.stats import cauchy
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> mean, var, skew, kurt = cauchy.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(cauchy.ppf(0.01),
...                 cauchy.ppf(0.99), 100)
>>> ax.plot(x, cauchy.pdf(x),
...          'r-', lw=5, alpha=0.6, label='cauchy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = cauchy()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = cauchy.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], cauchy.cdf(vals))
True
```

Generate random numbers:

```python
>>> r = cauchy.rvs(size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```
Methods

- `rvs(loc=0, scale=1, size=1, random_state=None)`
  Random variates.

- `pdf(x, loc=0, scale=1)`
  Probability density function.

- `logpdf(x, loc=0, scale=1)`
  Log of the probability density function.

- `cdf(x, loc=0, scale=1)`
  Cumulative distribution function.

- `logcdf(x, loc=0, scale=1)`
  Log of the cumulative distribution function.

- `sf(x, loc=0, scale=1)`
  Survival function (also defined as 1 - cdf, but sf is sometimes more accurate).

- `logsf(x, loc=0, scale=1)`
  Log of the survival function.

- `ppf(q, loc=0, scale=1)`
  Percent point function (inverse of cdf — percentiles).

- `isf(q, loc=0, scale=1)`
  Inverse survival function (inverse of sf).

- `moment(n, loc=0, scale=1)`
  Non-central moment of order n.

- `stats(loc=0, scale=1, moments='mv')`
  Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').

- `entropy(loc=0, scale=1)`
  (Differential) entropy of the RV.

- `fit(data, loc=0, scale=1)`
  Parameter estimates for generic data.

- `expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)`
  Expected value of a function (of one argument) with respect to the distribution.

- `median(loc=0, scale=1)`
  Median of the distribution.

- `mean(loc=0, scale=1)`
  Mean of the distribution.

- `var(loc=0, scale=1)`
  Variance of the distribution.

- `std(loc=0, scale=1)`
  Standard deviation of the distribution.

- `interval(alpha, loc=0, scale=1)`
  Endpoints of the range that contains alpha percent of the distribution.

scipy.stats.chi = <scipy.stats._continuous_distns.chi_gen object>
A chi continuous random variable.

As an instance of the rv_continuous class, chi object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.
Notes

The probability density function for $\chi$ is:

$$f(x, df) = x^{df-1} \exp(-x^2/2) \frac{2^{df/2-1}}{\gamma(df/2)}$$

for $x > 0$.

Special cases of $\chi$ are:

- $\chi(1, loc, scale)$ is equivalent to $\text{halfnorm}$
- $\chi(2, 0, scale)$ is equivalent to $\text{rayleigh}$
- $\chi(3, 0, scale)$ is equivalent to $\text{maxwell}$

$\chi$ takes $df$ as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the $\text{loc}$ and $\text{scale}$ parameters. Specifically, $\chi.pdf(x, df, \text{loc}, \text{scale})$ is identically equivalent to $\chi.pdf(y, df) / \text{scale}$ with $y = (x - \text{loc}) / \text{scale}$.

Examples

```python
>>> from scipy.stats import chi
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
def = 78
>>> mean, var, skew, kurt = chi.stats(df, moments='mvsk')

Display the probability density function (pdf):

```python
>>> x = np.linspace(chi.ppf(0.01, df),...
... chi.ppf(0.99, df), 100)
>>> ax.plot(x, chi.pdf(x, df),...
... 'r-', lw=5, alpha=0.6, label='chis pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = chi(df)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = chi.ppf([0.001, 0.5, 0.999], df)
>>> np.allclose([0.001, 0.5, 0.999], chi.cdf(vals, df))
True
```

Generate random numbers:

```python
>>> r = chi.rvs(df, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```
### scipy.stats.chi2

A chi-squared continuous random variable.

As an instance of the `rv_continuous` class, `chi2` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

<td>Standard deviation of the distribution.</td>
</tr>
<tr>
<td><code>interval(alpha, df, loc=0, scale=1)</code></td>
<td>Endpoints of the range that contains alpha percent of the distribution.</td>
</tr>
</tbody>
</table>
Notes

The probability density function for `chi2` is:

\[ f(x, df) = \frac{1}{(2\gamma(df/2))(x/2)^{df/2-1}} \exp(-x/2) \]

`chi2` takes `df` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `chi2.pdf(x, df, loc, scale)` is identically equivalent to `chi2.pdf(y, df) / scale` with \( y = (x - loc) / scale \).

Examples

```python
>>> from scipy.stats import chi2
>>> import matplotlib.pyplot as plt

Calculate a few first moments:

```python
>>> df = 55
>>> mean, var, skew, kurt = chi2.stats(df, moments='mvsk')
```  
Display the probability density function (pdf):

```python
>>> x = np.linspace(chi2.ppf(0.01, df),
...                  chi2.ppf(0.99, df), 100)
>>> ax.plot(x, chi2.pdf(x, df),
...          'r-', lw=5, alpha=0.6, label='chi2 pdf')
```  
Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = chi2(df)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```  
Check accuracy of cdf and ppf:

```python
>>> vals = chi2.ppf([0.001, 0.5, 0.999], df)
>>> np.allclose([0.001, 0.5, 0.999], chi2.cdf(vals, df))
```  
Generate random numbers:

```python
>>> r = chi2.rvs(df, size=1000)
```  
And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

```python
scipy.stats.cosine = <scipy.stats._continuous_distns.cosine_gen object>
```

A cosine continuous random variable.

As an instance of the `rv_continuous` class, `cosine` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.
Notes

The cosine distribution is an approximation to the normal distribution. The probability density function for cosine is:

\[
    f(x) = \frac{1}{2\pi} (1 + \cos(x))
\]

for \(-\pi \leq x \leq \pi\).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, \(\text{cosine.pdf}(x, \text{loc}, \text{scale})\) is identically equivalent to \(\text{cosine.pdf}(y) / \text{scale}\) with \(y = (x - \text{loc}) / \text{scale}\).

Examples

```python
>>> from scipy.stats import cosine
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> mean, var, skew, kurt = cosine.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(cosine.ppf(0.01),
...                 cosine.ppf(0.99), 100)
>>> ax.plot(x, cosine.pdf(x), 'r-', lw=5, alpha=0.6, label='cosine pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = cosine()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python

### scipy.stats.crystalball = <scipy.stats._continuous_distns.crystalball_gen object>

Crystalball distribution

As an instance of the `rv_continuous` class, `crystalball` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.
Notes

The probability density function for *crystalball* is:

\[
 f(x, \beta, m) = \begin{cases} 
 N \exp(-x^2/2), & \text{for } x > -\beta \\
 N A (B - x)^{-m} & \text{for } x \leq -\beta 
\end{cases}
\]

where \( A = (m/|\beta|)^n \exp(-|\beta|^2/2) \), \( B = m/|\beta| - |\beta| \) and \( N \) is a normalisation constant.

*crystalball* takes \( \beta \) and \( m \) as shape parameters. \( \beta \) defines the point where the pdf changes from a power-law to a gaussian distribution \( m \) is power of the power-law tail.

References

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \( \text{loc} \) and \( \text{scale} \) parameters. Specifically, \( \text{crystalball.pdf}(x, \beta, m, \text{loc}, \text{scale}) \) is identically equivalent to \( \text{crystalball.pdf}(y, \beta, m) / \text{scale} \) with \( y = (x - \text{loc}) / \text{scale} \).

[R628]

Examples

```python
>>> from scipy.stats import crystalball
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

>>> beta, m = 2, 3
>>> mean, var, skew, kurt = crystalball.stats(beta, m, moments='mvsk')

Display the probability density function (pdf):

>>> x = np.linspace(crystalball.ppf(0.01, beta, m),
...     crystalball.ppf(0.99, beta, m), 100)
>>> ax.plot(x, crystalball.pdf(x, beta, m),
...     'r-', lw=5, alpha=0.6, label='crystalball pdf')

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

>>> rv = crystalball(beta, m)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')

Check accuracy of cdf and ppf:

>>> vals = crystalball.ppf([0.001, 0.5, 0.999], beta, m)
>>> np.allclose([0.001, 0.5, 0.999], crystalball.cdf(vals, beta, m))
True

Generate random numbers:

>>> r = crystalball.rvs(beta, m, size=1000)

And compare the histogram:
```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

```python
scipy.stats.dgamma = <scipy.stats._continuous_distns.dgamma_gen object>
```

A double gamma continuous random variable.

As an instance of the `rv_continuous` class, `dgamma` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

#### Notes

The probability density function for `dgamma` is:

\[
f(x, a) = \frac{1}{2\gamma(a)} |x|^{a-1} \exp(-|x|)
\]

for \(a > 0\).

`dgamma` takes \(a\) as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `dgamma.pdf(x, a, loc, scale)` is identically equivalent to `dgamma.pdf(y, a) / scale` with \(y = (x - \text{loc}) / \text{scale}\).

#### Examples

```python
>>> from scipy.stats import dgamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```
Calculate a few first moments:

```python
>>> a = 1.1
>>> mean, var, skew, kurt = dgamma.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(dgamma.ppf(0.01, a),
...     dgamma.ppf(0.99, a), 100)
>>> ax.plot(x, dgamma.pdf(x, a),
...     'r-', lw=5, alpha=0.6, label='dgamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = dgamma(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = dgamma.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], dgamma.cdf(vals, a))
True
```

Generate random numbers:

```python
>>> r = dgamma.rvs(a, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.dweibull = <scipy.stats.continuous_distns.dweibull_gen object>

A double Weibull continuous random variable.

As an instance of the rv_continuous class, dweibull object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for dweibull is:

\[ f(x, c) = c/2|x|^{c-1}\exp(-|x|^c) \]

dweibull takes \(d\) as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, dweibull.pdf(x, \(c\), loc, scale) is identically equivalent to dweibull.pdf(y, \(c\)) / scale with y = (x - loc) / scale.

Examples

```python
>>> from scipy.stats import dweibull
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:
Display the probability density function (pdf):

```python
>>> x = np.linspace(dweibull.ppf(0.01, c),
...                 dweibull.ppf(0.99, c), 100)
>>> ax.plot(x, dweibull.pdf(x, c),
...          'r-', lw=5, alpha=0.6, label='dweibull pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = dweibull(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = dweibull.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], dweibull.cdf(vals, c))
True
```

Generate random numbers:

```python
>>> r = dweibull.rvs(c, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.erlang = <scipy.stats._continuous_distns.erlang_gen object>**

An Erlang continuous random variable.

As an instance of the `rv_continuous` class, `erlang` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

`gamma`

**Notes**

The Erlang distribution is a special case of the Gamma distribution, with the shape parameter \(a\) an integer. Note that this restriction is not enforced by `erlang`. It will, however, generate a warning the first time a non-integer value is used for the shape parameter.

Refer to `gamma` for examples.

</table>

\[ f(x) = \exp(-x) \]

for \(x \geq 0\).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \(\text{loc}\) and \(\text{scale}\) parameters. Specifically, \(\text{expn.pdf}(x, \text{loc}, \text{scale})\) is identically equivalent to \(\text{expn.pdf}(y) / \text{scale} \) with \(y = (x - \text{loc}) / \text{scale}\).

A common parameterization for \(\text{expn}\) is in terms of the rate parameter \(\lambda\), such that \(\text{pdf} = \lambda \times \exp(-\lambda \times x)\). This parameterization corresponds to using \(\text{scale} = 1 / \lambda\).

Examples

```python
>>> from scipy.stats import expon
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```
Calculate a few first moments:

```python
>>> mean, var, skew, kurt = expon.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(expon.ppf(0.01),
                     ...                     expon.ppf(0.99), 100)
>>> ax.plot(x, expon.pdf(x),
          ...          'r-', lw=5, alpha=0.6, label='expon pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = expon()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = expon.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], expon.cdf(vals))
```

Generate random numbers:

```python
>>> r = expon.rvs(size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

</table>

**scipy.stats.exponnorm** = <scipy.stats._continuous_distns.exponnorm_gen object>

An exponentially modified Normal continuous random variable.

As an instance of the `rv_continuous` class, `exponnorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `exponnorm` is:

\[
f(x, K) = \frac{1}{2K} \exp\left(\frac{1}{2K^2}\right) \exp(-x/K) \erfc - \frac{x - 1/K}{\sqrt{2}}
\]

where the shape parameter \(K > 0\).  

It can be thought of as the sum of a normally distributed random value with mean `loc` and sigma `scale` and an exponentially distributed random number with a pdf proportional to \(\exp(-\lambda \cdot x)\) where \(\lambda = (K \ast scale)^{-1}\).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `exponnorm.pdf(x, K, loc, scale)` is identically equivalent to `exponnorm.pdf(y, K) / scale` with `y = (x - loc) / scale`.

An alternative parameterization of this distribution (for example, in Wikipedia) involves three parameters, \(\mu\), \(\lambda\) and \(\sigma\). In the present parameterization this corresponds to having `loc` and `scale` equal to \(\mu\) and \(\sigma\), respectively, and shape parameter \(K = 1/\sigma \lambda\).

New in version 0.16.0.
Examples

```python
>>> from scipy.stats import exponnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> K = 1.5
>>> mean, var, skew, kurt = exponnorm.stats(K, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(exponnorm.ppf(0.01, K),
...                 exponnorm.ppf(0.99, K), 100)
>>> ax.plot(x, exponnorm.pdf(x, K),
...          'r-', lw=5, alpha=0.6, label='exponnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = exponnorm(K)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = exponnorm.ppf([0.001, 0.5, 0.999], K)
>>> np.allclose([0.001, 0.5, 0.999], exponnorm.cdf(vals, K))
True
```

Generate random numbers:

```python
>>> r = exponnorm.rvs(K, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.exponweib = <scipy.stats._continuous_distns.exponweib_gen object>

An exponentiated Weibull continuous random variable.

As an instance of the rv_continuous class, exponweib object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.
Notes

The probability density function for \texttt{exponweib} is:

\[ f(x, a, c) = ac(1 - \exp(-xc))^{a-1} \exp(-xc)x^{c-1} \]

for \( x > 0, a > 0, c > 0 \).

\texttt{exponweib} takes \( a \) and \( c \) as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \texttt{loc} and \texttt{scale} parameters. Specifically, \texttt{exponweib.pdf(x, a, c, loc, scale)} is identically equivalent to \texttt{exponweib.pdf(y, a, c) / scale} with \( y = (x - \text{loc}) / \text{scale} \).

Examples

```python
>>> from scipy.stats import exponweib
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> a, c = 2.89, 1.95
>>> mean, var, skew, kurt = exponweib.stats(a, c, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(exponweib.ppf(0.01, a, c),
                  exponweib.ppf(0.99, a, c), 100)
>>> ax.plot(x, exponweib.pdf(x, a, c),
          'r-', lw=5, alpha=0.6, label='exponweib pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = exponweib(a, c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = exponweib.ppf([0.001, 0.5, 0.999], a, c)
>>> np.allclose([0.001, 0.5, 0.999], exponweib.cdf(vals, a, c))
True
```

Generate random numbers:

```python
>>> r = exponweib.rvs(a, c, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.exponpow** = `<scipy.stats._continuous_distns.exponpow_gen object>`

An exponential power continuous random variable.

As an instance of the `rv_continuous` class, `exponpow` object inherits from it a collection of generic meth-
The probability density function for `exponpow` is:

\[ f(x, b) = b x^{b-1} \exp(1 + x^b - \exp(x^b)) \]

for \( x \geq 0, \ b > 0 \). Note that this is a different distribution from the exponential power distribution that is also known under the names “generalized normal” or “generalized Gaussian”.

`exponpow` takes \( b \) as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `exponpow.pdf(x, b, loc, scale)` is identically equivalent to `exponpow.pdf(y, b) / scale` with \( y = (x - loc) / scale \).

**References**

http://www.math.wm.edu/~leemis/chart/UDR/PDFs/Exponentialpower.pdf

**Examples**

```python
>>> from scipy.stats import exponpow
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> b = 2.7
>>> mean, var, skew, kurt = exponpow.stats(b, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(exponpow.ppf(0.01, b),
...                 exponpow.ppf(0.99, b), 100)
>>> ax.plot(x, exponpow.pdf(x, b),
...         'r-', lw=5, alpha=0.6, label='exponpow pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = exponpow(b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = exponpow.ppf([0.001, 0.5, 0.999], b)
>>> np.allclose([0.001, 0.5, 0.999], exponpow.cdf(vals, b))
```

Generate random numbers:

```python
>>> r = exponpow.rvs(b, size=1000)
```

And compare the histogram:
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()

```

scipy.stats.f = <scipy.stats._continuous_distns.f_gen object>
An F continuous random variable.

As an instance of the `rv_continuous` class, \( f \) object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for \( f \) is:

\[
f(x, df_1, df_2) = \frac{df_2^{df_2/2} df_1^{df_1/2} x^{df_1/2 - 1}}{(df_2 + df_1 x)^{(df_1+df_2)/2} B(df_1/2, df_2/2)}
\]

for \( x > 0 \).

\( f \) takes \( dfn \) and \( dfd \) as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \( loc \) and \( scale \) parameters. Specifically, \( f.pdf(x, dfn, dfd, loc, scale) \) is identically equivalent to \( f.pdf(y, dfn, dfd) / scale \) with \( y = (x - loc) / scale \).

**Examples**

```python
>>> from scipy.stats import f
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> dfn, dfd = 29, 18
>>> mean, var, skew, kurt = f.stats(dfn, dfd, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(f.ppf(0.01, dfn, dfd), ...
... f.ppf(0.99, dfn, dfd), 100)
>>> ax.plot(x, f.pdf(x, dfn, dfd), ...
... 'r-', lw=5, alpha=0.6, label='f pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = f(dfn, dfd)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = f.ppf([0.001, 0.5, 0.999], dfn, dfd)
>>> np.allclose([0.001, 0.5, 0.999], f.cdf(vals, dfn, dfd))
True
```

Generate random numbers:

```python
>>> r = f.rvs(dfn, dfd, size=1000)
```

And compare the histogram:
```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.fatiguelife** = <scipy.stats._continuous_distns.fatiguelife_gen object>

A fatigue-life (Birnbaum-Saunders) continuous random variable.

As an instance of the `rv_continuous` class, `fatiguelife` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `fatiguelife` is:

\[
f(x, c) = \frac{x + 1}{2c\sqrt{2\pi x^3}} \exp\left(-\frac{(x-1)^2}{2xc^2}\right)
\]

for \(x > 0\).

`fatiguelife` takes \(c\) as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `fatiguelife.pdf(x, c, loc, scale)` is identically equivalent to `fatiguelife.pdf(y, c) / scale` with \(y = (x - \text{loc}) / \text{scale}\).

### References

[R636]
Examples

```python
>>> from scipy.stats import fatiguelife
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> c = 29
    >>> mean, var, skew, kurt = fatiguelife.stats(c, moments='mvsk')
```  
Display the probability density function (pdf):

```python
>>> x = np.linspace(fatiguelife.ppf(0.01, c),
    ...        fatiguelife.ppf(0.99, c), 100)
>>> ax.plot(x, fatiguelife.pdf(x, c),
    ...        'r-', lw=5, alpha=0.6, label='fatiguelife pdf')
```  
Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = fatiguelife(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```  
Check accuracy of cdf and ppf:

```python
>>> vals = fatiguelife.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], fatiguelife.cdf(vals, c))
True
```  
Generate random numbers:

```python
>>> r = fatiguelife.rvs(c, size=1000)
```  
And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.fisk = <scipy.stats._continuous_distns.fisk_gen object>

A Fisk continuous random variable.

The Fisk distribution is also known as the log-logistic distribution, and equals the Burr distribution with d == 1.
fisk takes \( c \) as a shape parameter.

As an instance of the \texttt{rv_continuous} class, fisk object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

burr

**Notes**

The probability density function for \texttt{fisk} is:

\[
f(x,c) = cx^{-c-1}(1+x^{-c})^{-2}
\]

for \( x > 0 \).

\texttt{fisk} takes \( c \) as a shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \texttt{loc} and \texttt{scale} parameters. Specifically, \texttt{fisk.pdf(x, c, loc, scale)} is identically equivalent to \texttt{fisk.pdf(y, c) / scale} with \( y = (x - \texttt{loc}) / \texttt{scale} \).

**Examples**

```python
>>> from scipy.stats import fisk
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

>>> c = 3.09
>>> mean, var, skew, kurt = fisk.stats(c, moments='mvsk')

>>> x = np.linspace(fisk.ppf(0.01, c), fisk.ppf(0.99, c), 100)
>>> ax.plot(x, fisk.pdf(x, c), 'r-', lw=5, alpha=0.6, label='fisk pdf')

>>> ax.plot(x, fisk.pdf(x, c), 'k-', lw=2, label='frozen pdf')

`scipy.stats.foldcauchy = <scipy.stats._continuous_distns.foldcauchy_gen object>`
A folded Cauchy continuous random variable.

As an instance of the `rv_continuous` class, `foldcauchy` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `foldcauchy` is:

\[
f(x, c) = \frac{1}{\pi(1 + (x - c)^2)} + \frac{1}{\pi(1 + (x + c)^2)}
\]

for \(x \geq 0\):

`foldcauchy` takes \(c\) as a shape parameter.

**Examples**

```python
>>> from scipy.stats import foldcauchy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> c = 4.72
>>> mean, var, skew, kurt = foldcauchy.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(foldcauchy.ppf(0.01, c), foldcauchy.ppf(0.99, c), 100)
>>> ax.plot(x, foldcauchy.pdf(x, c), 'r-', lw=5, alpha=0.6, label='foldcauchy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = foldcauchy(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = foldcauchy.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], foldcauchy.cdf(vals, c))
```

Generate random numbers:

```python
>>> r = foldcauchy.rvs(c, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```
Methods

**scipy.stats.foldnorm = <scipy.stats._continuous_distns.foldnorm_gen object>**

A folded normal continuous random variable.

As an instance of the `rv_continuous` class, `foldnorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.
Notes

The probability density function for \texttt{foldnorm} is:

\[
f(x, c) = \sqrt{2/\pi} \cosh(cx) \exp\left(-\frac{x^2 + c^2}{2}\right)
\]

for \(c \geq 0\).

\texttt{foldnorm} takes \(c\) as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \texttt{loc} and \texttt{scale} parameters. Specifically, \texttt{foldnorm.pdf}(x, c, \texttt{loc}, \texttt{scale}) is identically equivalent to \texttt{foldnorm.pdf}(y, c) / \texttt{scale} with \(y = (x - \texttt{loc}) / \texttt{scale}\).

Examples

```python
>>> from scipy.stats import foldnorm
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
c = 1.95
mean, var, skew, kurt = foldnorm.stats(c, moments='mvsk')
```  
Display the probability density function (pdf):

```python
>>> x = np.linspace(foldnorm.ppf(0.01, c),
...                 foldnorm.ppf(0.99, c), 100)
>>> ax.plot(x, foldnorm.pdf(x, c),
...          'r-', lw=5, alpha=0.6, label='foldnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = foldnorm(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of \texttt{cdf} and \texttt{ppf}:

```python
>>> vals = foldnorm.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], foldnorm.cdf(vals, c))
True
```

Generate random numbers:

```python
>>> r = foldnorm.rvs(c, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```
Methods

- `rvs(c, loc=0, scale=1, size=1, random_state=None)` Random variates.
- `pdf(x, c, loc=0, scale=1)` Probability density function.
- `logpdf(x, c, loc=0, scale=1)` Log of the probability density function.
- `cdf(x, c, loc=0, scale=1)` Cumulative distribution function.
- `logcdf(x, c, loc=0, scale=1)` Log of the cumulative distribution function.
- `sf(x, c, loc=0, scale=1)` Survival function (also defined as 1 - cdf, but sf is sometimes more accurate).
- `logsf(x, c, loc=0, scale=1)` Log of the survival function.
- `ppf(q, c, loc=0, scale=1)` Percent point function (inverse of cdf — percentiles).
- `isf(q, c, loc=0, scale=1)` Inverse survival function (inverse of sf).
- `moment(n, c, loc=0, scale=1)` Non-central moment of order n
- `stats(c, loc=0, scale=1, moments='mv')` Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
- `entropy(c, loc=0, scale=1)` (Differential) entropy of the RV.
- `fit(data, c, loc=0, scale=1)` Parameter estimates for generic data.
- `expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)` Expected value of a function (of one argument) with respect to the distribution.
- `median(c, loc=0, scale=1)` Median of the distribution.
- `mean(c, loc=0, scale=1)` Mean of the distribution.
- `var(c, loc=0, scale=1)` Variance of the distribution.
- `std(c, loc=0, scale=1)` Standard deviation of the distribution.
- `interval(alpha, c, loc=0, scale=1)` Endpoints of the range that contains alpha percent of the distribution.

`scipy.stats.frechet_r = <scipy.stats._continuous_distns.frechet_r_gen object>`
A frechet_r continuous random variable.

As an instance of the rv_continuous class, frechet_r object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.
Examples

```python
>>> from scipy.stats import frechet_r
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> c =
>>> mean, var, skew, kurt = frechet_r.stats(c, moments='mvsk')
```  
Display the probability density function (pdf):

```python
>>> x = np.linspace(frechet_r.ppf(0.01, c),
... frechet_r.ppf(0.99, c), 100)
>>> ax.plot(x, frechet_r.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='frechet_r pdf')
```  
Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = frechet_r(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```  
Check accuracy of cdf and ppf:

```python
>>> vals = frechet_r.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], frechet_r.cdf(vals, c))
True
```  
Generate random numbers:

```python
>>> r = frechet_r.rvs(c, size=1000)
```  
And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.genlogistic = <scipy.stats._continuous_distns.genlogistic_gen object>

A generalized logistic continuous random variable.

As an instance of the `rv_continuous` class, `genlogistic` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.
Notes

The probability density function for \texttt{genlogistic} is:

\[ f(x, c) = c \frac{\exp(-x)}{(1 + \exp(-x))^{c+1}} \]

for \( x > 0, c > 0 \).

\texttt{genlogistic} takes \( c \) as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \texttt{loc} and \texttt{scale} parameters. Specifically, \texttt{genlogistic.pdf(x, c, loc, scale)} is identically equivalent to \texttt{genlogistic.pdf(y, c)} / \texttt{scale} with \( y = (x - \texttt{loc}) / \texttt{scale} \).

Examples

```python
>>> from scipy.stats import genlogistic
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

>>> c = 0.412
>>> mean, var, skew, kurt = genlogistic.stats(c, moments='mvsk')

>>> x = np.linspace(genlogistic.ppf(0.01, c),
...                   genlogistic.ppf(0.99, c), 100)
>>> ax.plot(x, genlogistic.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='genlogistic pdf')

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = genlogistic(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of \texttt{cdf} and \texttt{ppf}:

```python
>>> vals = genlogistic.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], genlogistic.cdf(vals, c))
True
```

Generate random numbers:

```python
>>> r = genlogistic.rvs(c, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.gennorm = <scipy.stats._continuous_distns.gennorm_gen object>

A generalized normal continuous random variable.

As an instance of the rv_continuous class, gennorm object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.
See also:

- **laplace** Laplace distribution
- **norm** normal distribution

**Notes**

The probability density function for \texttt{gennorm} is [R646]:

\[
gennorm.pdf(x, \text{beta}) = \frac{\text{beta}}{2 \gamma(1/\text{beta})} \exp(-|x|^{\text{beta}})
\]

\texttt{gennorm} takes \(\beta\) as a shape parameter. For \(\beta = 1\), it is identical to a Laplace distribution. For \(\beta = 2\), it is identical to a normal distribution (with \textit{scale} = 1/\sqrt{2}).

**References**

[R646]

**Examples**

```python
>>> from scipy.stats import gennorm
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> beta = 1.3
>>> mean, var, skew, kurt = gennorm.stats(beta, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(gennorm.ppf(0.01, beta),
...                 gennorm.ppf(0.99, beta), 100)
>>> ax.plot(x, gennorm.pdf(x, beta),
...         'r-', lw=5, alpha=0.6, label='gennorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = gennorm(beta)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = gennorm.ppf([0.001, 0.5, 0.999], beta)
>>> np.allclose([0.001, 0.5, 0.999], gennorm.cdf(vals, beta))
True
```

Generate random numbers:

```python
>>> r = gennorm.rvs(beta, size=1000)
```

And compare the histogram:
```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```
Methods

- `rvs(beta, loc=0, scale=1, size=1, random_state=None)`
  Random variates.

- `pdf(x, beta, loc=0, scale=1)`
  Probability density function.

- `logpdf(x, beta, loc=0, scale=1)`
  Log of the probability density function.

- `cdf(x, beta, loc=0, scale=1)`
  Cumulative distribution function.

- `logcdf(x, beta, loc=0, scale=1)`
  Log of the cumulative distribution function.

- `sf(x, beta, loc=0, scale=1)`
  Survival function (also defined as \(1 - cdf\), but \(sf\) is sometimes more accurate).

- `logsf(x, beta, loc=0, scale=1)`
  Log of the survival function.

- `ppf(q, beta, loc=0, scale=1)`
  Percent point function (inverse of \(cdf\) — percentiles).

- `isf(q, beta, loc=0, scale=1)`
  Inverse survival function (inverse of \(sf\)).

- `moment(n, beta, loc=0, scale=1)`
  Non-central moment of order \(n\).

- `stats(beta, loc=0, scale=1, moments='mv')`
  Mean (‘m’), variance (‘v’), skew (‘s’), and/or kurtosis (‘k’).

- `entropy(beta, loc=0, scale=1)`
  (Differential) entropy of the RV.

- `fit(data, beta, loc=0, scale=1)`
  Parameter estimates for generic data.

- `expect(func, args=(beta,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)`
  Expected value of a function (of one argument) with respect to the distribution.

- `median(beta, loc=0, scale=1)`
  Median of the distribution.

- `mean(beta, loc=0, scale=1)`
  Mean of the distribution.

- `var(beta, loc=0, scale=1)`
  Variance of the distribution.

- `std(beta, loc=0, scale=1)`
  Standard deviation of the distribution.

- `interval(alpha, beta, loc=0, scale=1)`
  Endpoints of the range that contains \(alpha\) percent of the distribution.

```python
scipy.stats.genpareto = <scipy.stats._continuous_distns.genpareto_gen object>
```

A generalized Pareto continuous random variable.

As an instance of the `rv_continuous` class, `genpareto` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `genpareto` is:

\[
f(x, c) = (1 + cx)^{-1-1/c}
\]

defined for \(x \geq 0\) if \(c \geq 0\), and for \(0 \leq x \leq -1/c\) if \(c < 0\).

`genpareto` takes \(c\) as a shape parameter.

For \(c == 0\), `genpareto` reduces to the exponential distribution, `expon`:

\[
f(x, c = 0) = \exp(-x)
\]

For \(c == -1\), `genpareto` is uniform on \([0, 1]\):

\[
f(x, c = -1) = x
\]

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `genpareto.pdf(x, c, loc, scale)` is identically equivalent to `genpareto.pdf(y, c) / scale` with \(y = (x - loc) / scale\).
Examples

```python
>>> from scipy.stats import genpareto
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
c = 0.1
mean, var, skew, kurt = genpareto.stats(c, moments='mvsk')
```n
Display the probability density function (pdf):

```python
x = np.linspace(genpareto.ppf(0.01, c),
                genpareto.ppf(0.99, c), 100)
x = np.linspace(genpareto.ppf(0.01, c),
                genpareto.ppf(0.99, c), 100)
ax.plot(x, genpareto.pdf(x, c),
        'r-', lw=5, alpha=0.6, label='genpareto pdf')

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
rv = genpareto(c)
ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
vals = genpareto.ppf([0.001, 0.5, 0.999], c)
np.allclose([0.001, 0.5, 0.999], genpareto.cdf(vals, c))
True
```

Generate random numbers:

```python
r = genpareto.rvs(c, size=1000)
```

And compare the histogram:

```python
ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
ax.legend(loc='best', frameon=False)
plt.show()
```

`scipy.stats.genexpon = <scipy.stats._continuous_distns.genexpon_gen object>`

A generalized exponential continuous random variable.

As an instance of the `rv_continuous` class, `genexpon` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.
Notes

The probability density function for `genexpon` is:

\[
f(x, a, b, c) = (a + b(1 - \exp(-cx))) \exp(-ax - bx + \frac{b}{c}(1 - \exp(-cx)))
\]

for \(x \geq 0, a, b, c > 0\).

`genexpon` takes \(a, b\) and \(c\) as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, \(\text{genexpon.pdf}(x, a, b, c, \text{loc}, \text{scale})\) is identically equivalent to \(\text{genexpon.pdf}(y, a, b, c) / \text{scale}\) with \(y = (x - \text{loc}) / \text{scale}\).

References

Examples

```python
>>> from scipy.stats import genexpon
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
... Calculate a few first moments:
... a, b, c = 9.13, 16.2, 3.28
... mean, var, skew, kurt = genexpon.stats(a, b, c, moments='mvsk')
... Display the probability density function (pdf):
... x = np.linspace(genexpon.ppf(0.01, a, b, c),
... ... genexpon.ppf(0.99, a, b, c), 100)
... ... ax.plot(x, genexpon.pdf(x, a, b, c),
... ... 'r-', lw=5, alpha=0.6, label='genexpon pdf')
... Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.
... Freeze the distribution and display the frozen pdf:
... rv = genexpon(a, b, c)
... ... ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
... Check accuracy of cdf and ppf:
... vals = genexpon.ppf([0.001, 0.5, 0.999], a, b, c)
... ... np.allclose([0.001, 0.5, 0.999], genexpon.cdf(vals, a, b, c))
... True
... Generate random numbers:
... r = genexpon.rvs(a, b, c, size=1000)
... And compare the histogram:
```
```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

</tbody>
</table>

```python
scipy.stats.genextreme = <scipy.stats._continuous_distns.genextreme_gen object>
```

A generalized extreme value continuous random variable.

As an instance of the `rv_continuous` class, `genextreme` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

`gumbel_r`

**Notes**

For \( c = 0 \), `genextreme` is equal to `gumbel_r`. The probability density function for `genextreme` is:

\[
f(x, c) = \begin{cases} 
\exp(-\exp(-x))\exp(-x) & \text{for } c = 0 \\
\exp(-(1-cx)^{1/c})(1-cx)^{1/c-1} & \text{for } x \leq 1/c, c > 0 
\end{cases}
\]

Note that several sources and software packages use the opposite convention for the sign of the shape parameter \( c \).

`genextreme` takes \( c \) as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `genextreme.pdf(x, c, loc, scale)` is identically equivalent to `genextreme.pdf(y, c) / scale` with \( y = (x - \text{loc}) / \text{scale} \).
Examples

```python
>>> from scipy.stats import genextreme
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:
```n
c = -0.1
>>> mean, var, skew, kurt = genextreme.stats(c, moments='mvsk')

Display the probability density function (pdf):
```n
>>> x = np.linspace(genextreme.ppf(0.01, c),
...                  genextreme.ppf(0.99, c), 100)
>>> ax.plot(x, genextreme.pdf(x, c),
...          'r-', lw=5, alpha=0.6, label='genextreme pdf')

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:
```n
>>> rv = genextreme(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')

Check accuracy of cdf and ppf:
```n
>>> vals = genextreme.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], genextreme.cdf(vals, c))
True

Generate random numbers:
```n
>>> r = genextreme.rvs(c, size=1000)

And compare the histogram:
```n
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.gausshyper = <scipy.stats._continuous_distns.gausshyper_gen object>
A Gauss hypergeometric continuous random variable.

As an instance of the rv_continuous class, gausshyper object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.
Notes

The probability density function for \texttt{gausshyper} is:

\[
f(x, a, b, c, z) = C x^{a-1} (1 - x)^{b-1} (1 + zx)^{-c}
\]

for \(0 \leq x \leq 1\), \(a > 0\), \(b > 0\), and \(C = \frac{1}{B(a,b)F[2,1][c,a,a+b,-z]}\)

\texttt{gausshyper} takes \(a, b, c\) and \(z\) as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \texttt{loc} and \texttt{scale} parameters. Specifically, \texttt{gausshyper.pdf(x, a, b, c, z, loc, scale)} is identically equivalent to \texttt{gausshyper.pdf(y, a, b, c, z) / scale} with \(y = (x - \texttt{loc}) / \texttt{scale}\).

Examples

```python
>>> from scipy.stats import gausshyper
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> a, b, c, z = 13.8, 3.12, 2.51, 5.18
>>> mean, var, skew, kurt = gausshyper.stats(a, b, c, z, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(gausshyper.ppf(0.01, a, b, c, z),
...                 gausshyper.ppf(0.99, a, b, c, z), 100)
>>> ax.plot(x, gausshyper.pdf(x, a, b, c, z),
...         'r-', lw=5, alpha=0.6, label='gausshyper pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = gausshyper(a, b, c, z)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of \texttt{cdf} and \texttt{ppf}:

```python
>>> vals = gausshyper.ppf([0.001, 0.5, 0.999], a, b, c, z)
>>> np.allclose([0.001, 0.5, 0.999], gausshyper.cdf(vals, a, b, c, z))
```

Generate random numbers:

```python
>>> r = gausshyper.rvs(a, b, c, z, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

</tbody>
</table>

scipy.stats.gamma = <scipy.stats._continuous_distns.gamma_gen object>

A gamma continuous random variable.
As an instance of the `rv_continuous` class, `gamma` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**
`erlang`, `expon`

**Notes**
The probability density function for `gamma` is:

\[
 f(x, a) = \frac{x^{a-1} \exp(-x)}{\gamma(a)}
\]

for \(x \geq 0, a > 0\). Here \(\gamma(a)\) refers to the gamma function.

`gamma` has a shape parameter \(a\) which needs to be set explicitly.

When \(a\) is an integer, \(\gamma\) reduces to the Erlang distribution, and when \(a = 1\) to the exponential distribution.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gamma.pdf(x, a, loc, scale)` is identically equivalent to `gamma.pdf(y, a) / scale` with \(y = (x - loc) / scale\).

**Examples**
```python
>>> from scipy.stats import gamma
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> a = 1.99
>>> mean, var, skew, kurt = gamma.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(gamma.ppf(0.01, a),
... gamma.ppf(0.99, a), 100)
>>> ax.plot(x, gamma.pdf(x, a),
... 'r-', lw=5, alpha=0.6, label='gamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = gamma(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

```python
>>> vals = gamma.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], gamma.cdf(vals, a))
```

Generate random numbers:

```python
>>> r = gamma.rvs(a, size=1000)
```
And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.gengamma = <scipy.stats._continuous_distns.gengamma_gen object>
A generalized gamma continuous random variable.

As an instance of the rv_continuous class, gengamma object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes
The probability density function for gengamma is:

\[ f(x, a, c) = \frac{|c| x^{ca-1} \exp(-x^c)}{\gamma(a)} \]

for \( x \geq 0, a > 0, \) and \( c \neq 0 \).

gengamma takes \( a \) and \( c \) as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, gengamma.pdf(\( x, a, c, \) loc, scale) is identically equivalent to gengamma.pdf(\( y, a, c \)) / scale with \( y = (x - \text{loc}) / \text{scale} \).

Examples

```python
>>> from scipy.stats import gengamma
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

>>> a, c = 4.42, -3.12
>>> mean, var, skew, kurt = gengamma.stats(a, c, moments='mvsk')

>>> x = np.linspace(gengamma.ppf(0.01, a, c),
...                 gengamma.ppf(0.99, a, c), 100)
>>> ax.plot(x, gengamma.pdf(x, a, c),
...         r'-', lw=5, alpha=0.6, label='gengamma pdf')

`scipy.stats.genhalflogistic = <scipy.stats._continuous_distns.genhalflogistic_gen object>`

A generalized half-logistic continuous random variable.

As an instance of the `rv_continuous` class, `genhalflogistic` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `genhalflogistic` is:

\[
f(x, c) = \frac{2(1 - cx)^{1/(c-1)}}{[1 + (1 - cx)^{1/c}]^2}
\]

for \(0 \leq x \leq 1/c\), and \(c > 0\).

`genhalflogistic` takes \(c\) as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `genhalflogistic.pdf(x, c, loc, scale)` is identically equivalent to `genhalflogistic.pdf(y, c) / scale` with \(y = (x - loc) / scale\).
Examples

```python
>>> from scipy.stats import genhalflogistic
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> c = 0.773
>>> mean, var, skew, kurt = genhalflogistic.stats(c, moments='mvsk')
``` 

Display the probability density function (pdf):

```python
>>> x = np.linspace(genhalflogistic.ppf(0.01, c),
...                 genhalflogistic.ppf(0.99, c), 100)
>>> ax.plot(x, genhalflogistic.pdf(x, c),
...          'r-', lw=5, alpha=0.6, label='genhalflogistic pdf')
``` 

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = genhalflogistic(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
``` 

Check accuracy of cdf and ppf:

```python
>>> vals = genhalflogistic.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], genhalflogistic.cdf(vals, c))
True
``` 

Generate random numbers:

```python
>>> r = genhalflogistic.rvs(c, size=1000)
``` 

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```
### Methods

- **rvs(c, loc=0, scale=1, size=1, random_state=None)**: Random variates.
- **pdf(x, c, loc=0, scale=1)**: Probability density function.
- **logpdf(x, c, loc=0, scale=1)**: Log of the probability density function.
- **cdf(x, c, loc=0, scale=1)**: Cumulative distribution function.
- **logcdf(x, c, loc=0, scale=1)**: Log of the cumulative distribution function.
- **sf(x, c, loc=0, scale=1)**: Survival function (also defined as 1 – cdf, but sf is sometimes more accurate).
- **logsf(x, c, loc=0, scale=1)**: Log of the survival function.
- **ppf(q, c, loc=0, scale=1)**: Percent point function (inverse of cdf — percentiles).
- **isf(q, c, loc=0, scale=1)**: Inverse survival function (inverse of sf).
- **moment(n, c, loc=0, scale=1)**: Non-central moment of order n.
- **stats(c, loc=0, scale=1, moments='mv')**: Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
- **entropy(c, loc=0, scale=1)**: (Differential) entropy of the RV.
- **fit(data, c, loc=0, scale=1)**: Parameter estimates for generic data.
- **expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)**: Expected value of a function (of one argument) with respect to the distribution.
- **median(c, loc=0, scale=1)**: Median of the distribution.
- **mean(c, loc=0, scale=1)**: Mean of the distribution.
- **var(c, loc=0, scale=1)**: Variance of the distribution.
- **std(c, loc=0, scale=1)**: Standard deviation of the distribution.
- **interval(alpha, c, loc=0, scale=1)**: Endpoints of the range that contains alpha percent of the distribution.

**scipy.stats.gilbrat** = <scipy.stats._continuous_distns.gilbrat_gen object>

A Gilbrat continuous random variable.

As an instance of the `rv_continuous` class, `gilbrat` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.
Notes

The probability density function for `gilbrat` is:

\[ f(x) = \frac{1}{x\sqrt{2\pi}} \exp\left(-\frac{1}{2}(\log(x))^2\right) \]

`gilbrat` is a special case of `lognorm` with \( s = 1 \).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gilbrat.pdf(x, loc, scale)` is identically equivalent to `gilbrat.pdf(y) / scale` with \( y = (x - loc) / scale \).

Examples

```python
>>> from scipy.stats import gilbrat
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> mean, var, skew, kurt = gilbrat.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(gilbrat.ppf(0.01),
...                  gilbrat.ppf(0.99), 100)
>>> ax.plot(x, gilbrat.pdf(x),
...          'r-', lw=5, alpha=0.6, label='gilbrat pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = gilbrat()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = gilbrat.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], gilbrat.cdf(vals))
```

Generate random numbers:

```python
>>> r = gilbrat.rvs(size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.gompertz = <scipy.stats._continuous_distns.gompertz_gen object>

A Gompertz (or truncated Gumbel) continuous random variable.

As an instance of the \texttt{rv_continuous} class, \texttt{gompertz} object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.
Notes

The probability density function for *gompertz* is:

\[ f(x, c) = c \exp(x) \exp(-c(e^x - 1)) \]

for \( x \geq 0, c > 0 \).

*gompertz* takes \( c \) as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, \( gompertz.pdf(x, c, \text{loc, scale}) \) is identically equivalent to \( gompertz.pdf(y, c) / \text{scale} \) with \( y = (x - \text{loc}) / \text{scale} \).

Examples

```python
>>> from scipy.stats import gompertz
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> c = 0.947
>>> mean, var, skew, kurt = gompertz.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(gompertz.ppf(0.01, c),
...                 gompertz.ppf(0.99, c), 100)
>>> ax.plot(x, gompertz.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='gompertz pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = gompertz(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of *cdf* and *ppf*:

```python
>>> vals = gompertz.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], gompertz.cdf(vals, c))
True
```

Generate random numbers:

```python
>>> r = gompertz.rvs(c, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.gumbel_r = <scipy.stats._continuous_distns.gumbel_r_gen object>`

A right-skewed Gumbel continuous random variable.

As an instance of the `rv_continuous` class, `gumbel_r` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.
See also:

gumbel_l, gompertz, genextreme

Notes

The probability density function for \texttt{gumbel\_r} is:

\[
f(x) = \exp(-(x + e^{-x}))
\]

The Gumbel distribution is sometimes referred to as a type I Fisher-Tippett distribution. It is also related to the extreme value distribution, log-Weibull and Gompertz distributions.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \texttt{loc} and \texttt{scale} parameters. Specifically, \texttt{gumbel\_r.pdf(x, loc, scale)} is identically equivalent to \texttt{gumbel\_r.pdf(y) / scale} with \( y = (x - \text{loc}) / \text{scale} \).

Examples

```python
>>> from scipy.stats import gumbel_r
>>> import matplotlib.pyplot as plt

Calculate a few first moments:

```python
>>> mean, var, skew, kurt = gumbel_r.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(gumbel_r.ppf(0.01),
...     gumbel_r.ppf(0.99), 100)
>>> ax.plot(x, gumbel_r.pdf(x),
...         'r-', lw=5, alpha=0.6, label='gumbel_r pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = gumbel_r()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = gumbel_r.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], gumbel_r.cdf(vals))
True
```

Generate random numbers:

```python
>>> r = gumbel_r.rvs(size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

- `rvs(loc=0, scale=1, size=1, random_state=None)`: Random variates.
- `pdf(x, loc=0, scale=1)`: Probability density function.
- `logpdf(x, loc=0, scale=1)`: Log of the probability density function.
- `cdf(x, loc=0, scale=1)`: Cumulative distribution function.
- `logcdf(x, loc=0, scale=1)`: Log of the cumulative distribution function.
- `sf(x, loc=0, scale=1)`: Survival function (also defined as \(1 - \text{cdf}\), but \(sf\) is sometimes more accurate).
- `logsf(x, loc=0, scale=1)`: Log of the survival function.
- `ppf(q, loc=0, scale=1)`: Percent point function (inverse of \(\text{cdf}\) — percentiles).
- `isf(q, loc=0, scale=1)`: Inverse survival function (inverse of \(sf\)).
- `moment(n, loc=0, scale=1)`: Non-central moment of order \(n\).
- `stats(loc=0, scale=1, moments='mv')`: Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
- `entropy(loc=0, scale=1)`: (Differential) entropy of the RV.
- `fit(data, loc=0, scale=1)`: Parameter estimates for generic data.
- `expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)`: Expected value of a function (of one argument) with respect to the distribution.
- `median(loc=0, scale=1)`: Median of the distribution.
- `mean(loc=0, scale=1)`: Mean of the distribution.
- `var(loc=0, scale=1)`: Variance of the distribution.
- `std(loc=0, scale=1)`: Standard deviation of the distribution.
- `interval(alpha, loc=0, scale=1)`: Endpoints of the range that contains alpha percent of the distribution.

*scipy.stats.gumbel_l = <scipy.stats._continuous_distns.gumbel_l_gen object>*

A left-skewed Gumbel continuous random variable.

As an instance of the `rv_continuous` class, `gumbel_l` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.
See also:

`gumbel_r`, `gompertz`, `genextreme`

**Notes**

The probability density function for `gumbel_l` is:

\[ f(x) = \exp(x - e^x) \]

The Gumbel distribution is sometimes referred to as a type I Fisher-Tippett distribution. It is also related to the extreme value distribution, log-Weibull and Gompertz distributions.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gumbel_l.pdf(x, loc, scale)` is identically equivalent to `gumbel_l.pdf(y) / scale` with \( y = (x - \text{loc}) / \text{scale} \).

**Examples**

```python
>>> from scipy.stats import gumbel_l
>>> import matplotlib.pyplot as plt

fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> mean, var, skew, kurt = gumbel_l.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(gumbel_l.ppf(0.01),
...                 gumbel_l.ppf(0.99), 100)
>>> ax.plot(x, gumbel_l.pdf(x),
...         'r-', lw=5, alpha=0.6, label='gumbel_l pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = gumbel_l()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = gumbel_l.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], gumbel_l.cdf(vals))
```

Generate random numbers:

```python
>>> r = gumbel_l.rvs(size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

```python
scipy.stats.halfcauchy = <scipy.stats._continuous_distns.halfcauchy_gen object>
```

A Half-Cauchy continuous random variable.

As an instance of the `rv_continuous` class, `halfcauchy` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.
Notes

The probability density function for `halfcauchy` is:

\[
f(x) = \frac{2}{\pi(1 + x^2)}
\]

for \(x \geq 0\).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `halfcauchy.pdf(x, loc, scale)` is identically equivalent to `halfcauchy.pdf(y) / scale` with \(y = (x - loc) / scale\).

Examples

```python
>>> from scipy.stats import halfcauchy

`scipy.stats.halflogistic = <scipy.stats._continuous_distns.halflogistic_gen object>`

A half-logistic continuous random variable.

As an instance of the `rv_continuous` class, `halflogistic` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.
Notes

The probability density function for \( \text{halflogistic} \) is:

\[
f(x) = \frac{2e^{-x}}{(1 + e^{-x})^2} = \frac{1}{2} \text{sech}(x/2)^2
\]

for \( x \geq 0 \).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \( \text{loc} \) and \( \text{scale} \) parameters. Specifically, \( \text{halflogistic.pdf}(x, \text{loc}, \text{scale}) \) is identically equivalent to \( \text{halflogistic.pdf}(y) / \text{scale} \) with \( y = (x - \text{loc}) / \text{scale} \).

Examples

```python
>>> from scipy.stats import halflogistic
>>> import matplotlib.pyplot as plt

Calculate a few first moments:

```python
>>> mean, var, skew, kurt = halflogistic.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(halflogistic.ppf(0.01), ...
...     halflogistic.ppf(0.99), 100)
>>> ax.plot(x, halflogistic.pdf(x), ...
...     'r-', lw=5, alpha=0.6, label='halflogistic pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = halflogistic()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = halflogistic.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], halflogistic.cdf(vals))
True
```

Generate random numbers:

```python
>>> r = halflogistic.rvs(size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```
scipy.stats.halfnorm = <scipy.stats._continuous_distns.halfnorm_gen object>

A half-normal continuous random variable.

As an instance of the `rv_continuous` class, `halfnorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for halfnorm is:

\[ f(x) = \sqrt{\frac{2}{\pi}} e^{-\frac{x^2}{2}} \]

for \( x > 0 \).

halfnorm is a special case of \( \chi \) with \( df = 1 \).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, \( \text{halfnorm.pdf}(x, \text{loc}, \text{scale}) \) is identically equivalent to \( \text{halfnorm.pdf}(y) / \text{scale} \) with \( y = (x - \text{loc}) / \text{scale} \).

Examples

```python
>>> from scipy.stats import halfnorm
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> mean, var, skew, kurt = halfnorm.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(halfnorm.ppf(0.01),...
...               halfnorm.ppf(0.99), 100)
>>> ax.plot(x, halfnorm.pdf(x),...
...         'r-', lw=5, alpha=0.6, label='halfnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = halfnorm()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = halfnorm.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], halfnorm.cdf(vals))
True
```

Generate random numbers:

```python
>>> r = halfnorm.rvs(size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

```python
scipy.stats.halfgennorm = <scipy.stats._continuous_distns.halfgennorm_gen object>
```

The upper half of a generalized normal continuous random variable.

As an instance of the `rv_continuous` class, `halfgennorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.
See also:

gennorm      generalized normal distribution
expon        exponential distribution
halfnorm     half normal distribution

Notes

The probability density function for halfgennorm is:

\[ f(x, \beta) = \frac{\beta}{\gamma(1/\beta)} \exp(-|x|^\beta) \]

gennorm takes \( \beta \) as a shape parameter. For \( \beta = 1 \), it is identical to an exponential distribution. For \( \beta = 2 \), it is identical to a half normal distribution (with \( \text{scale} = 1/\sqrt{2} \)).

References

[R647]

Examples

```python
>>> from scipy.stats import halfgennorm
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> beta = 0.675
>>> mean, var, skew, kurt = halfgennorm.stats(beta, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(halfgennorm.ppf(0.01, beta),
...                 halfgennorm.ppf(0.99, beta), 100)
>>> ax.plot(x, halfgennorm.pdf(x, beta),
...         'r-', lw=5, alpha=0.6, label='halfgennorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = halfgennorm(beta)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = halfgennorm.ppf([0.001, 0.5, 0.999], beta)
>>> np.allclose([0.001, 0.5, 0.999], halfgennorm.cdf(vals, beta))
True
```

Generate random numbers:

```python
>>> r = halfgennorm.rvs(beta, size=1000)
```

And compare the histogram:

```python
```
```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.hypsecant = <scipy.stats._continuous_distns.hypsecant_gen object>**

A hyperbolic secant continuous random variable.

As an instance of the `rv_continuous` class, `hypsecant` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `hypsecant` is:

\[ f(x) = \frac{1}{\pi \text{sech}(x)} \]

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `hypsecant.pdf(x, loc, scale)` is identically equivalent to `hypsecant.pdf(y) / scale` with `y = (x - loc) / scale`.

**Examples**

```python
>>> from scipy.stats import hypsecant
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:
Display the probability density function (pdf):

```python
>>> x = np.linspace(hypsecant.ppf(0.01),
...                 hypsecant.ppf(0.99), 100)
>>> ax.plot(x, hypsecant.pdf(x),
...          'r-', lw=5, alpha=0.6, label='hypsecant pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = hypsecant()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = hypsecant.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], hypsecant.cdf(vals))
```

Generate random numbers:

```python
>>> r = hypsecant.rvs(size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)

### scipy.stats.invgamma = <scipy.stats._continuous_distns.invgamma_gen object>

An inverted gamma continuous random variable.

As an instance of the `rv_continuous` class, `invgamma` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

#### Notes

The probability density function for `invgamma` is:

\[
    f(x, a) = \frac{x^{-a-1}}{\gamma(a)} \exp\left(-\frac{1}{x}\right)
\]

for \( x > 0, a > 0 \).

`invgamma` takes \( a \) as a shape parameter.

`invgamma` is a special case of `gengamma` with \( c == -1 \).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `invgamma.pdf(x, a, loc, scale)` is identically equivalent to `invgamma.pdf(y, a) / scale` with \( y = (x - loc) / scale \).

#### Examples

```python
>>> from scipy.stats import invgamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```
Calculate a few first moments:

```python
>>> a = 4.07
>>> mean, var, skew, kurt = invgamma.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(invgamma.ppf(0.01, a),
...                 invgamma.ppf(0.99, a), 100)
>>> ax.plot(x, invgamma.pdf(x, a),
...          'r-', lw=5, alpha=0.6, label='invgamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = invgamma(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = invgamma.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], invgamma.cdf(vals, a))
```

Generate random numbers:

```python
>>> r = invgamma.rvs(a, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.invgauss = <scipy.stats._continuous_distns.invgauss_gen object>

An inverse Gaussian continuous random variable.

As an instance of the rv_continuous class, invgauss object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for invgauss is:

\[
 f(x, \mu) = \frac{1}{\sqrt{2\pi x^3}} \exp\left( -\frac{(x - \mu)^2}{2x\mu^2} \right)
\]

for \( x > 0 \).

invgauss takes \( \mu \) as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, invgauss.pdf(x, mu, loc, scale) is identically equivalent to invgauss.pdf(y, mu) / scale with y = (x - loc) / scale.

When \( \mu \) is too small, evaluating the cumulative distribution function will be inaccurate due to cdf(mu -> 0) = inf * 0. NaNs are returned for \( \mu \leq 0.0028 \).

Examples
>>> from scipy.stats import invgauss
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> mu = 0.145
>>> mean, var, skew, kurt = invgauss.stats(mu, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(invgauss.ppf(0.01, mu),
... invgauss.ppf(0.99, mu), 100)
>>> ax.plot(x, invgauss.pdf(x, mu),
... 'r-', lw=5, alpha=0.6, label='invgauss pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = invgauss(mu)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = invgauss.ppf([0.001, 0.5, 0.999], mu)
>>> np.allclose([0.001, 0.5, 0.999], invgauss.cdf(vals, mu))
True
```

Generate random numbers:

```python
>>> r = invgauss.rvs(mu, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()

**scipy.stats.invweibull = <scipy.stats._continuous_distns.invweibull_gen object>**

An inverted Weibull continuous random variable.

As an instance of the `rv_continuous` class, `invweibull` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.
Notes

The probability density function for \texttt{invweibull} is:

\[
f(x, c) = cx^{-c-1} \exp(-x^{-c})
\]

for \(x > 0', c > 0'.

\texttt{invweibull} takes \(c\) as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \texttt{loc} and \texttt{scale} parameters. Specifically, \texttt{invweibull.pdf}(x, c, loc, scale) is identically equivalent to \texttt{invweibull.pdf}(y, c) / scale with \(y = (x - \text{loc}) / \text{scale}\).

References

Examples

```python
>>> from scipy.stats import invweibull
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

>>> c = 10.6
>>> mean, var, skew, kurt = invweibull.stats(c, moments='mvsk')

Display the probability density function (pdf):

>>> x = np.linspace(invweibull.ppf(0.01, c), ...
... invweibull.ppf(0.99, c), 100)
>>> ax.plot(x, invweibull.pdf(x, c), ...
... 'r-', lw=5, alpha=0.6, label='invweibull pdf')

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

>>> rv = invweibull(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')

Check accuracy of cdf and ppf:

>>> vals = invweibull.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], invweibull.cdf(vals, c))
True

Generate random numbers:

>>> r = invweibull.rvs(c, size=1000)

And compare the histogram:

>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```
Methods

- rvs(c, loc=0, scale=1, size=1, random_state=None)  
  Random variates.

- pdf(x, c, loc=0, scale=1)  
  Probability density function.

- logpdf(x, c, loc=0, scale=1)  
  Log of the probability density function.

- cdf(x, c, loc=0, scale=1)  
  Cumulative distribution function.

- logcdf(x, c, loc=0, scale=1)  
  Log of the cumulative distribution function.

- sf(x, c, loc=0, scale=1)  
  Survival function (also defined as 1 - cdf, but sf is sometimes more accurate).

- logsf(x, c, loc=0, scale=1)  
  Log of the survival function.

- ppf(q, c, loc=0, scale=1)  
  Percent point function (inverse of cdf — percentiles).

- isf(q, c, loc=0, scale=1)  
  Inverse survival function (inverse of sf).

- moment(n, c, loc=0, scale=1)  
  Non-central moment of order n

- stats(c, loc=0, scale=1, moments='mv')  
  Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').

- entropy(c, loc=0, scale=1)  
  (Differential) entropy of the RV.

- fit(data, c, loc=0, scale=1)  
  Parameter estimates for generic data.

- expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)  
  Expected value of a function (of one argument) with respect to the distribution.

- median(c, loc=0, scale=1)  
  Median of the distribution.

- mean(c, loc=0, scale=1)  
  Mean of the distribution.

- var(c, loc=0, scale=1)  
  Variance of the distribution.

- std(c, loc=0, scale=1)  
  Standard deviation of the distribution.

- interval(alpha, c, loc=0, scale=1)  
  Endpoints of the range that contains alpha percent of the distribution

**scipy.stats.johnsonsb = <scipy.stats._continuous_distns.johnsonsb_gen object>**

A Johnson SB continuous random variable.

As an instance of the `rv_continuous` class, `johnsonsb` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.
See also:

johnsonsu

Notes

The probability density function for \texttt{johnsonsb} is:

\[
\frac{b}{x(1-x)} \phi \left( a + b \log \frac{x}{1-x} \right)
\]

for \(0 < x < 1\) and \(a, b > 0\), and \(\phi\) is the normal pdf.

\texttt{johnsonsb} takes \(a\) and \(b\) as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \texttt{loc} and \texttt{scale} parameters. Specifically, \texttt{johnsonsb.pdf}(x, a, b, loc, scale) is identically equivalent to \texttt{johnsonsb.pdf}(y, a, b) / scale with \(y = (x - \text{loc}) / \text{scale}\).

Examples

```python
>>> from scipy.stats import johnsonsb
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
def johnsonsb.stats(a, b, moments='mvsk')
```  
Display the probability density function (pdf):

```python
>>> x = np.linspace(johnsonsb.ppf(0.01, a, b), johnsonsb.ppf(0.99, a, b), 100)
>>> ax.plot(x, johnsonsb.pdf(x, a, b), 'r-', lw=5, alpha=0.6, label='johnsonsb pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = johnsonsb(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = johnsonsb.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], johnsonsb.cdf(vals, a, b))
True
```

Generate random numbers:

```python
>>> r = johnsonsb.rvs(a, b, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.johnsu = <scipy.stats._continuous_distns.johnsu_gen object>**

A Johnson SU continuous random variable.

As an instance of the `rv_continuous` class, johnsu object inherits from it a collection of generic
methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

`johnsonsb`

**Notes**

The probability density function for `johnsonsu` is:

\[
f(x, a, b) = \frac{b}{\sqrt{x^2 + 1}} \phi(a + b \log(x + \sqrt{x^2 + 1}))
\]

for all \(x, a, b > 0\), and \(\phi\) is the normal pdf.

`johnsonsu` takes \(a\) and \(b\) as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \(\text{loc}\) and \(\text{scale}\) parameters. Specifically, \(\text{johnsonsu.pdf}(x, a, b, \text{loc}, \text{scale})\) is identically equivalent to \(\text{johnsonsu.pdf}(y, a, b) / \text{scale}\) with \(y = (x - \text{loc}) / \text{scale}\).

**Examples**

```python
>>> from scipy.stats import johnsonsu
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> a, b = 2.55, 2.25
>>> mean, var, skew, kurt = johnsonsu.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(johnsonsu.ppf(0.01, a, b), johnsonsu.ppf(0.99, a, b), 100)
>>> ax.plot(x, johnsonsu.pdf(x, a, b), 'r-', lw=5, alpha=0.6, label='johnsonsu pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = johnsonsu(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = johnsonsu.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], johnsonsu.cdf(vals, a, b))
True
```

Generate random numbers:

```python
>>> r = johnsonsu.rvs(a, b, size=1000)
```

And compare the histogram:
```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.kappa4 = <scipy.stats._continuous_distns.kappa4_gen object>**

Kappa 4 parameter distribution.

As an instance of the `rv_continuous` class, `kappa4` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for kappa4 is:

\[
f(x, h, k) = (1 - kx)^{1/k - 1}(1 - h(1 - kx)^{1/k})^{1/h - 1}
\]

if \( h \) and \( k \) are not equal to 0.

If \( h \) or \( k \) are zero then the pdf can be simplified:

- \( h = 0 \) and \( k \) != 0:
  
  \[
  \text{kappa4.pdf}(x, h, k) = (1.0 - k*x)^{(1.0/k - 1.0)}* \exp(-(1.0 - k*x)^{(1.0/k)})
  \]

- \( h \) != 0 and \( k = 0 \):
  
  \[
  \text{kappa4.pdf}(x, h, k) = \exp(-x)*((1.0 - h*\exp(-x))^{(1.0/h - 1.0)}
  \]

1826 Chapter 5. API Reference
h = 0 and k = 0:

\[
\text{kappa4.pdf}(x, h, k) = \exp(-x)\cdot\exp(-\exp(-x))
\]

kappa4 takes \(h\) and \(k\) as shape parameters.

The kappa4 distribution returns other distributions when certain \(h\) and \(k\) values are used.

J.C. Finney, “Optimization of a Skewed Logistic Distribution With Respect to the Kolmogorov-Smirnov Test”, A Dissertation Submitted to the Graduate Faculty of the Louisiana State University and Agricultural and Mechanical College, (August, 2004), http://digitalcommons.lsu.edu/cgi/viewcontent.cgi?article=4671&context=gradschool_dissertations

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \(\text{loc}\) and \(\text{scale}\) parameters. Specifically, \(\text{kappa4.pdf}(x, h, k, \text{loc}, \text{scale})\) is identically equivalent to \(\text{kappa4.pdf}(y, h, k) / \text{scale}\) with \(y = (x - \text{loc}) / \text{scale}\).

Examples

```python
>>> from scipy.stats import kappa4
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> h, k = 0.1, 0
>>> mean, var, skew, kurt = kappa4.stats(h, k, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(kappa4.ppf(0.01, h, k),
...                    kappa4.ppf(0.99, h, k), 100)
>>> ax.plot(x, kappa4.pdf(x, h, k),
...         'r-', lw=5, alpha=0.6, label='kappa4 pdf')
```
Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = kappa4(h, k)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = kappa4.ppf([0.001, 0.5, 0.999], h, k)
>>> np.allclose([0.001, 0.5, 0.999], kappa4.cdf(vals, h, k))
```

Generate random numbers:

```python
>>> r = kappa4.rvs(h, k, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats. `kappa3` = `<scipy.stats._continuous_distns.kappa3_gen object>`

Kappa 3 parameter distribution.

As an instance of the `rv_continuous` class, `kappa3` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `kappa` is:

\[
f(x, a) = \begin{cases} 
a[a + x^a]^{-(a+1)/a}, & \text{for } x > 0 \\
0, & \text{for } x \leq 0
\end{cases}
\]

\`kappa3\` takes \(a\) as a shape parameter and \(a > 0\).

References

5.27. Statistical functions (scipy.stats) 1829
The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the 
loc and scale parameters. Specifically, kappa3.pdf(x, a, loc, scale) is identically equivalent to 
kappa3.pdf(y, a) / scale with y = (x - loc) / scale.

Examples

```python
>>> from scipy.stats import kappa3
>>> import matplotlib.pyplot as plt

fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

>>> a = 1
>>> mean, var, skew, kurt = kappa3.stats(a, moments='mvsk')

Display the probability density function (pdf):

```python
>>> x = np.linspace(kappa3.ppf(0.01, a),
... kappa3.ppf(0.99, a), 100)
>>> ax.plot(x, kappa3.pdf(x, a),
... 'r-', lw=5, alpha=0.6, label='kappa3 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. 
This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = kappa3(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = kappa3.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], kappa3.cdf(vals, a))
True
```

Generate random numbers:

```python
>>> r = kappa3.rvs(a, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.ksone** = <scipy.stats._continuous_distns.ksone_gen object>

General Kolmogorov-Smirnov one-sided test.

As an instance of the *rv_continuous* class, *ksone* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.
Examples

```python
>>> from scipy.stats import ksone
>>> import matplotlib.pyplot as plt

Calculate a few first moments:

```python
>>> n = 1e+03
>>> mean, var, skew, kurt = ksone.stats(n, moments='mvsk')
``` Display the probability density function (pdf):

```python
>>> x = np.linspace(ksone.ppf(0.01, n),
...                 ksone.ppf(0.99, n), 100)
>>> ax.plot(x, ksone.pdf(x, n),
...         'r-', lw=5, alpha=0.6, label='ksone pdf')
``` Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = ksone(n)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
``` Check accuracy of cdf and ppf:

```python
>>> vals = ksone.ppf([0.001, 0.5, 0.999], n)
>>> np.allclose([0.001, 0.5, 0.999], ksone.cdf(vals, n))
True
``` Generate random numbers:

```python
>>> r = ksone.rvs(n, size=1000)
``` And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.kstwobign = <scipy.stats._continuous_distns.kstwobign_gen object>**

Kolmogorov-Smirnov two-sided test for large \(N\).

As an instance of the `rv_continuous` class, `kstwobign` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.
Examples

```python
>>> from scipy.stats import kstwobign
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> mean, var, skew, kurt = kstwobign.stats(moments='mvsk')
```Display the probability density function (pdf):

```python
>>> x = np.linspace(kstwobign.ppf(0.01),

... kstwobign.ppf(0.99), 100)
>>> ax.plot(x, kstwobign.pdf(x),

... 'r-', lw=5, alpha=0.6, label='kstwobign pdf')

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = kstwobign()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python

`scipy.stats.laplace = <scipy.stats._continuous_distns.laplace_gen object>`

A Laplace continuous random variable.

As an instance of the `rv_continuous` class, `laplace` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

5.27. Statistical functions (scipy.stats)
Notes

The probability density function for laplace is:

\[ f(x) = \frac{1}{2} \exp(-|x|) \]

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, \( \text{laplace.pdf}(x, \text{loc}, \text{scale}) \) is identically equivalent to \( \text{laplace.pdf}(y) / \text{scale} \) with \( y = (x - \text{loc}) / \text{scale} \).

Examples

```python
>>> from scipy.stats import laplace
>>> import matplotlib.pyplot as plt

Calculate a few first moments:
```n
```python
>>> mean, var, skew, kurt = laplace.stats(moments='mvsk')
```

Display the probability density function (pdf):
```python
>>> x = np.linspace(laplace.ppf(0.01),
...                 laplace.ppf(0.99), 100)
>>> ax.plot(x, laplace.pdf(x),
...          'r-', lw=5, alpha=0.6, label='laplace pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:
```python
>>> rv = laplace()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:
```python
>>> vals = laplace.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], laplace.cdf(vals))
True
```

Generate random numbers:
```python
>>> r = laplace.rvs(size=1000)
```

And compare the histogram:
```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```
Methods

- `rvs(loc=0, scale=1, size=1, random_state=None)`: Random variates.
- `pdf(x, loc=0, scale=1)`: Probability density function.
- `logpdf(x, loc=0, scale=1)`: Log of the probability density function.
- `cdf(x, loc=0, scale=1)`: Cumulative distribution function.
- `logcdf(x, loc=0, scale=1)`: Log of the cumulative distribution function.
- `sf(x, loc=0, scale=1)`: Survival function (also defined as 1 - cdf, but sf is sometimes more accurate).
- `logsf(x, loc=0, scale=1)`: Log of the survival function.
- `ppf(q, loc=0, scale=1)`: Percent point function (inverse of cdf — percentiles).
- `isf(q, loc=0, scale=1)`: Inverse survival function (inverse of sf).
- `moment(n, loc=0, scale=1)`: Non-central moment of order n.
- `stats(loc=0, scale=1, moments='mv')`: Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
- `entropy(loc=0, scale=1)`: (Differential) entropy of the RV.
- `fit(data, loc=0, scale=1)`: Parameter estimates for generic data.
- `expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)`: Expected value of a function (of one argument) with respect to the distribution.
- `median(loc=0, scale=1)`: Median of the distribution.
- `mean(loc=0, scale=1)`: Mean of the distribution.
- `var(loc=0, scale=1)`: Variance of the distribution.
- `std(loc=0, scale=1)`: Standard deviation of the distribution.
- `interval(alpha, loc=0, scale=1)`: Endpoints of the range that contains alpha percent of the distribution.

`scipy.stats.levy = <scipy.stats._continuous_distns.levy_gen object>`

A Levy continuous random variable.

As an instance of the `rv_continuous` class, `levy` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.
See also:

levy_stable, levy_l

Notes
The probability density function for levy is:

\[ f(x) = \frac{1}{x \sqrt{2\pi x}} \exp\left(-\frac{1}{2x}\right) \]

for \( x > 0 \).

This is the same as the Levy-stable distribution with \( a = 1/2 \) and \( b = 1 \).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, levy.pdf(x, loc, scale) is identically equivalent to levy.pdf(y) / scale with \( y = (x - \text{loc}) / \text{scale} \).

Examples

```python
>>> from scipy.stats import levy
>>> import matplotlib.pyplot as plt

fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> mean, var, skew, kurt = levy.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(levy.ppf(0.01),
...                  levy.ppf(0.99), 100)

```

```python
>>> ax.plot(x, levy.pdf(x),
...          'r-', lw=5, alpha=0.6, label='levy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = levy()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = levy.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], levy.cdf(vals))
True
```

Generate random numbers:

```python
>>> r = levy.rvs(size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

#### scipy.stats.levy_l

A left-skewed Levy continuous random variable.

As an instance of the `rv_continuous` class, `levy_l` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

---

5.27. Statistical functions (scipy.stats) 1839
See also:

levy, levy_stable

Notes

The probability density function for levy_l is:

\[ f(x) = \frac{1}{|x|\sqrt{2\pi|x|}} \exp\left(-\frac{1}{2|x|}\right) \]

for \( x < 0 \).

This is the same as the Levy-stable distribution with \( a = 1/2 \) and \( b = -1 \).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, \( \text{levy_l.pdf}(x, \text{loc}, \text{scale}) \) is identically equivalent to \( \text{levy_l.pdf}(y) / \text{scale} \) with \( y = (x - \text{loc}) / \text{scale} \).

Examples

```python
>>> from scipy.stats import levy_l
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> mean, var, skew, kurt = levy_l.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(levy_l.ppf(0.01),
...                 levy_l.ppf(0.99), 100)
>>> ax.plot(x, levy_l.pdf(x),
...          'r-', lw=5, alpha=0.6, label='levy_l pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = levy_l()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = levy_l.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], levy_l.cdf(vals))
True
```

Generate random numbers:

```python
>>> r = levy_l.rvs(size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.logistic = <scipy.stats._continuous_distns.logistic_gen object>

A logistic (or Sech-squared) continuous random variable.

As an instance of the rv_continuous class, logistic object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes
The probability density function for logistic is:

\[ f(x) = \frac{\exp(-x)}{(1 + \exp(-x))^2} \]

logistic is a special case of genlogistic with c == 1.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, logistic.pdf(x, loc, scale) is identically equivalent
to \( \logistic(y) / \text{scale} \) with \( y = (x - \text{loc}) / \text{scale} \).

**Examples**

```python
>>> from scipy.stats import logistic
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> mean, var, skew, kurt = logistic.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(logistic.ppf(0.01), ...
...     logistic.ppf(0.99), 100)
>>> ax.plot(x, logistic.pdf(x), ...
...     'r-', lw=5, alpha=0.6, label='logistic pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = logistic()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = logistic.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], logistic.cdf(vals))
```

Generate random numbers:

```python
>>> r = logistic.rvs(size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

```
scipy.stats.loggamma = <scipy.stats._continuous_dists.loggamma_gen object>
```

A log gamma continuous random variable.

As an instance of the `rv_continuous` class, `loggamma` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.
Notes

The probability density function for \( \loggamma \) is:

\[
f(x, c) = \frac{\exp(cx - \exp(x))}{\gamma(c)}
\]

for all \( x, c > 0 \).

\( \loggamma \) takes \( c \) as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \( \text{loc} \) and \( \text{scale} \) parameters. Specifically, \( \loggamma.pdf(x, c, \text{loc}, \text{scale}) \) is identically equivalent to \( \loggamma.pdf(y, c) / \text{scale} \) with \( y = (x - \text{loc}) / \text{scale} \).

Examples

```python
>>> from scipy.stats import loggamma
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> c = 0.414
>>> mean, var, skew, kurt = loggamma.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(loggamma.ppf(0.01, c),
...                   loggamma.ppf(0.99, c), 100)
>>> ax.plot(x, loggamma.pdf(x, c),
...          'r-', lw=5, alpha=0.6, label='loggamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = loggamma(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = loggamma.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], loggamma.cdf(vals, c))
```

Generate random numbers:

```python
>>> r = loggamma.rvs(c, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

</tbody>
</table>

```python
scipy.stats.loglaplace = <scipy.stats._continuous_distns.loglaplace_gen object>
```

A log-Laplace continuous random variable.

As an instance of the `rv_continuous` class, `loglaplace` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.
Notes

The probability density function for loglaplace is:

\[ f(x, c) = \begin{cases} \frac{c}{2} x^{c-1} & \text{for } 0 < x < 1 \\ \frac{c}{2} x^{-c-1} & \text{for } x \geq 1 \end{cases} \]

for \( c > 0 \).

loglaplace takes \( c \) as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, \( \text{loglaplace.pdf}(x, c, \text{loc}, \text{scale}) \) is identically equivalent to \( \text{loglaplace.pdf}(y, c) / \text{scale} \) with \( y = (x - \text{loc}) / \text{scale} \).

References

Examples

```python
>>> from scipy.stats import loglaplace
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> c = 3.25
>>> mean, var, skew, kurt = loglaplace.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(loglaplace.ppf(0.01, c), ...
... loglaplace.ppf(0.99, c), 100)
>>> ax.plot(x, loglaplace.pdf(x, c), ...
... 'r-', lw=5, alpha=0.6, label='loglaplace pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = loglaplace(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = loglaplace.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], loglaplace.cdf(vals, c))
True
```

Generate random numbers:

```python
>>> r = loglaplace.rvs(c, size=1000)
```

And compare the histogram:
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()

```

scipy.stats.lognorm = <scipy.stats._continuous_distns.lognorm_gen object>
A lognormal continuous random variable.

As an instance of the `rv_continuous` class, `lognorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `lognorm` is:

\[
    f(x, s) = \frac{1}{sx\sqrt{2\pi}} \exp\left(-\frac{1}{2}\left(\frac{\log(x)}{s}\right)^2\right)
\]

for \(x > 0, s > 0\).

`lognorm` takes \(s\) as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `lognorm.pdf(x, s, loc, scale)` is identically equivalent to `lognorm.pdf(y, s) / scale` with \(y = (x - loc) / scale\).

A common parametrization for a lognormal random variable \(Y\) is in terms of the mean, \(\mu\), and standard deviation, \(\sigma\), of the unique normally distributed random variable \(X\) such that \(\exp(X) = Y\). This parametrization corresponds to setting \(s = \sigma\) and `scale = exp(mu)`.

**Examples**

```python
>>> from scipy.stats import lognorm
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> s = 0.954
>>> mean, var, skew, kurt = lognorm.stats(s, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(lognorm.ppf(0.01, s), ...
...                   lognorm.ppf(0.99, s), 100)
>>> ax.plot(x, lognorm.pdf(x, s), ...
...         'r-', lw=5, alpha=0.6, label='lognorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = lognorm(s)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = lognorm.ppf([0.001, 0.5, 0.999], s)
>>> np.allclose([0.001, 0.5, 0.999], lognorm.cdf(vals, s))
True
```

Generate random numbers:

```python
>>> r = lognorm.rvs(s, size=1000)
```
And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.lomax = <scipy.stats._continuous_distns.lomax_gen object>
A Lomax (Pareto of the second kind) continuous random variable.

As an instance of the rv_continuous class, lomax object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes
The Lomax distribution is a special case of the Pareto distribution, with (loc=-1.0).
The probability density function for lomax is:
\[ f(x, c) = \frac{c}{(1 + x)^{c+1}} \]
for \( x \geq 0, c > 0 \).
lomax takes \( c \) as a shape parameter.
The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, lomax.pdf(\( x, c, \text{loc}, \text{scale} \)) is identically equivalent to lomax.pdf(\( y, c \)) / scale with \( y = (x - \text{loc}) / \text{scale} \).

Examples
```python
>>> from scipy.stats import lomax
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

>>> c = 1.88
>>> mean, var, skew, kurt = lomax.stats(c, moments='mvsk')

Display the probability density function (pdf):

>>> x = np.linspace(lomax.ppf(0.01, c),
...     lomax.ppf(0.99, c), 100)
>>> ax.plot(x, lomax.pdf(x, c),
...     'r-', lw=5, alpha=0.6, label='lomax pdf')

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

>>> rv = lomax(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')

Check accuracy of cdf and ppf:

>>> vals = lomax.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], lomax.cdf(vals, c))
True

Generate random numbers:

>>> r = lomax.rvs(c, size=1000)

And compare the histogram:
```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

```python
scipy.stats.maxwell = <scipy.stats._continuous_distns.maxwell_gen object>
```
A Maxwell continuous random variable.

As an instance of the `rv_continuous` class, `maxwell` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

A special case of a chi distribution, with df = 3, loc = 0.0, and given scale = a, where a is the parameter used in the Mathworld description [R667].

The probability density function for `maxwell` is:

\[ f(x) = \sqrt{\frac{2}{\pi}} x^2 \exp(-x^2/2) \]

for \( x > 0 \).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `maxwell.pdf(x, loc, scale)` is identically equivalent to `maxwell.pdf(y) / scale` with \( y = (x - loc) / scale \).

**References**

[R667]

**Examples**

```python
>>> from scipy.stats import maxwell
>>> import matplotlib.pyplot as plt

fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> mean, var, skew, kurt = maxwell.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(maxwell.ppf(0.01), ...
... maxwell.ppf(0.99), 100)
>>> ax.plot(x, maxwell.pdf(x), ...
... 'r-', lw=5, alpha=0.6, label='maxwell pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = maxwell()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = maxwell.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], maxwell.cdf(vals))
True
```

Generate random numbers:

```python
>>> r = maxwell.rvs(size=1000)
```

And compare the histogram:
```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

</table>

```python
scipy.stats.mielke = <scipy.stats._continuous_distns.mielke_gen object>
```
A Mielke’s Beta-Kappa continuous random variable.

As an instance of the `rv_continuous` class, `mielke` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `mielke` is:

\[
f(x, k, s) = \frac{k x^{k-1}}{(1 + x^s)^{1+k/s}}
\]

for \(x > 0\).

`mielke` takes \(k\) and \(s\) as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `mielke.pdf(x, k, s, loc, scale)` is identically equivalent to `mielke.pdf(y, k, s) / scale` with \(y = (x - loc) / scale\).

**Examples**

```python
>>> from scipy.stats import mielke
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> k, s = 10.4, 3.6
>>> mean, var, skew, kurt = mielke.stats(k, s, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(mielke.ppf(0.01, k, s),
...                  mielke.ppf(0.99, k, s), 100)
>>> ax.plot(x, mielke.pdf(x, k, s), 'r-', lw=5, alpha=0.6, label='mielke pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = mielke(k, s)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = mielke.ppf([0.001, 0.5, 0.999], k, s)
>>> np.allclose([0.001, 0.5, 0.999], mielke.cdf(vals, k, s))
```

Generate random numbers:

```python
>>> r = mielke.rvs(k, s, size=1000)
```

And compare the histogram:
```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

```python
scipy.stats.nakagami = <scipy.stats._continuous_distns.nakagami_gen object>
```

A Nakagami continuous random variable.

As an instance of the `rv_continuous` class, `nakagami` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

#### Notes

The probability density function for `nakagami` is:

\[
f(x, \nu) = \frac{2\nu^\nu}{\Gamma(\nu)} x^{2\nu-1} \exp(-\nu x^2)
\]

for \( x > 0, \nu > 0 \).

`nakagami` takes \( \nu \) as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `nakagami.pdf(x, \nu, \text{loc}, \text{scale})` is identically equivalent to `nakagami.pdf(y, \nu) / \text{scale}` with \( y = (x - \text{loc}) / \text{scale} \).

#### Examples

```python
>>> from scipy.stats import nakagami
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```
Calculate a few first moments:

```python
>>> nu = 4.97
>>> mean, var, skew, kurt = nakagami.stats(nu, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(nakagami.ppf(0.01, nu),
...                   nakagami.ppf(0.99, nu), 100)
>>> ax.plot(x, nakagami.pdf(x, nu),
...         'r-', lw=5, alpha=0.6, label='nakagami pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = nakagami(nu)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = nakagami.ppf([0.001, 0.5, 0.999], nu)
>>> np.allclose([0.001, 0.5, 0.999], nakagami.cdf(vals, nu))
True
```

Generate random numbers:

```python
>>> r = nakagami.rvs(nu, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.ncx2 = <scipy.stats._continuous_distns.ncx2_gen object>

A non-central chi-squared continuous random variable.

As an instance of the rv_continuous class, ncx2 object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for \(ncx2\) is:

\[
f(x, df, nc) = \exp(-\frac{nc + x}{2}) \frac{1}{2}(x/nc)^{(df-2)/4} I[(df - 2)/2](\sqrt{ncx})\]

for \(x > 0\).

\(ncx2\) takes \(df\) and \(nc\) as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \(\text{loc}\) and \(\text{scale}\) parameters. Specifically, \(ncx2.pdf(x, df, nc, loc, scale)\) is identically equivalent to \(ncx2.pdf(y, df, nc) / scale\) with \(y = (x - loc) / scale\).

Examples

```python
>>> from scipy.stats import ncx2
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```
Calculate a few first moments:

```python
>>> df, nc = 21, 1.06
>>> mean, var, skew, kurt = ncx2.stats(df, nc, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(ncx2.ppf(0.01, df, nc),
... rcx2.ppf(0.99, df, nc), 100)
>>> ax.plot(x, ncx2.pdf(x, df, nc),
... rc-'r-', lw=5, alpha=0.6, label='ncx2 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = ncx2(df, nc)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = ncx2.ppf([0.001, 0.5, 0.999], df, nc)
>>> np.allclose([0.001, 0.5, 0.999], ncx2.cdf(vals, df, nc))
True
```

Generate random numbers:

```python

`scipy.stats.ncf = <scipy.stats._continuous_distns.ncf_gen object>`

A non-central F distribution continuous random variable.

As an instance of the `rv_continuous` class, `ncf` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `ncf` is:

\[
f(x; n_1, n_2, \lambda) = \exp\left(\frac{\lambda}{2} + \lambda n_1 \frac{x}{2(n_1 x + n_2)}\right) (n_2 + n_1 x)^{-\frac{n_1 + n_2}{2}} \gamma\left(\frac{n_1}{2}\right) \gamma\left(1 + \frac{n_2}{2}\right)
\]

\[
\times \left(\frac{L_{v_2/2}^{-1}\left(-\lambda n_1 \frac{x}{2(n_1 x + n_2)}\right)}{(B(v_1/2, v_2/2) \gamma\left(\frac{v_1 + v_2}{2}\right))}\right)
\]

for \(n_1 > 1, n_2, \lambda > 0\). Here \(n_1\) is the degrees of freedom in the numerator, \(n_2\) the degrees of freedom in the denominator, \(\lambda\) the non-centrality parameter, \(\gamma\) is the logarithm of the Gamma function, \(L_{v_2/2}^{-1}\) is a generalized Laguerre polynomial and \(B\) is the beta function.

`ncf` takes `df1, df2` and `nc` as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `ncf.pdf(x, dfn, dfd, nc, loc, scale)` is identically
equivalent to \( \text{ncf.pdf}(y, \text{dfn}, \text{dfd}, \text{nc}) / \text{scale} \) with \( y = (x - \text{loc}) / \text{scale} \).

**Examples**

```python
>>> from scipy.stats import ncf
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> dfn, dfd, nc = 27, 27, 0.416
>>> mean, var, skew, kurt = ncf.stats(dfn, dfd, nc, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(ncf.ppf(0.01, dfn, dfd, nc), ...
...     ncf.ppf(0.99, dfn, dfd, nc), 100)
>>> ax.plot(x, ncf.pdf(x, dfn, dfd, nc), ...
...     'r-', lw=5, alpha=0.6, label='ncf pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = ncf(dfn, dfd, nc)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = ncf.ppf([0.001, 0.5, 0.999], dfn, dfd, nc)
>>> np.allclose([0.001, 0.5, 0.999], ncf.cdf(vals, dfn, dfd, nc))
True
```

Generate random numbers:

```python
>>> r = ncf.rvs(dfn, dfd, nc, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.nct = <scipy.stats._continuous_distns.nct_gen object>
A non-central Student’s T continuous random variable.
As an instance of the `rv_continuous` class, `nct` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `nct` is:

\[
f(x, df, nc) = \frac{df^{df/2} \gamma(df + 1)}{2^{df/2} \exp(nc^2/2)(df + x^2)^{df/2} \gamma(df/2)}
\]

for \( df > 0 \).

`nct` takes `df` and `nc` as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `nct.pdf(x, df, nc, loc, scale)` is identically equivalent to `nct.pdf(y, df, nc)` / `scale` with \( y = (x - loc) / scale \).

**Examples**

```python
>>> from scipy.stats import nct
>>> import matplotlib.pyplot as plt

>>> df, nc = 14, 0.24

>>> mean, var, skew, kurt = nct.stats(df, nc, moments='mvsk')

>>> x = np.linspace(nct.ppf(0.01, df, nc), nct.ppf(0.99, df, nc), 100)

>>> ax.plot(x, nct.pdf(x, df, nc), 'r-', lw=5, alpha=0.6, label='nct pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

**Freeze the distribution and display the frozen pdf:**

```python
>>> rv = nct(df, nc)

>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

```python
>>> vals = nct.ppf([0.001, 0.5, 0.999], df, nc)

>>> np.allclose([0.001, 0.5, 0.999], nct.cdf(vals, df, nc))
True
```

Generate random numbers:

```python
>>> r = nct.rvs(df, nc, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.norm = <scipy.stats._continuous_distns.norm_gen object>**

A normal continuous random variable.

The location (loc) keyword specifies the mean. The scale (scale) keyword specifies the standard deviation.
As an instance of the `rv_continuous` class, `norm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `norm` is:

\[
    f(x) = \frac{\exp(-x^2/2)}{\sqrt{2\pi}}
\]

The survival function, `norm.sf`, is also referred to as the Q-function in some contexts (see, e.g., Wikipedia’s definition).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `norm.pdf(x, loc, scale)` is identically equivalent to `norm.pdf(y) / scale` with `y = (x - loc) / scale`.

**Examples**

```python
>>> from scipy.stats import norm
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
cache465
>>> mean, var, skew, kurt = norm.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
cache465
>>> x = np.linspace(norm.ppf(0.01), ...
... norm.ppf(0.99), 100)
>>> ax.plot(x, norm.pdf(x),
... 'r-', lw=5, alpha=0.6, label='norm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
cache465
>>> rv = norm()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
cache465
>>> vals = norm.ppf((0.001, 0.5, 0.999))
>>> np.allclose([0.001, 0.5, 0.999], norm.cdf(vals))
True
```

Generate random numbers:

```python
cache465
>>> r = norm.rvs(size=1000)
```

And compare the histogram:

```python
cache465
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()""

**scipy.stats.pareto** = <scipy.stats._continuous_distns.pareto_gen object>

A Pareto continuous random variable.

As an instance of the `rv_continuous` class, `pareto` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.
Notes

The probability density function for \texttt{pareto} is:

\[ f(x, b) = \frac{b}{x^{b+1}} \]

for \( x \geq 1, b > 0 \).

\texttt{pareto} takes \( b \) as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \texttt{loc} and \texttt{scale} parameters. Specifically, \texttt{pareto.pdf(x, b, loc, scale)} is identically equivalent to \texttt{pareto.pdf(y, b) / scale} with \( y = (x - \text{loc}) / \text{scale} \).

Examples

```python
>>> from scipy.stats import pareto
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> b = 2.62
>>> mean, var, skew, kurt = pareto.stats(b, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(pareto.ppf(0.01, b),
...                 pareto.ppf(0.99, b), 100)
>>> ax.plot(x, pareto.pdf(x, b),
...         'r-', lw=5, alpha=0.6, label='pareto pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” \texttt{RV} object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = pareto(b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of \texttt{cdf} and \texttt{ppf}:

```python
>>> vals = pareto.ppf([0.001, 0.5, 0.999], b)
>>> np.allclose([0.001, 0.5, 0.999], pareto.cdf(vals, b))
True
```

Generate random numbers:

```python
>>> r = pareto.rvs(b, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.pearson3 = <scipy.stats._continuous_distns.pearson3_gen object>

A pearson type III continuous random variable.

As an instance of the rv_continuous class, pearson3 object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.
Notes

The probability density function for \texttt{pearson3} is:

\[
f(x, \text{skew}) = \frac{|\beta|}{\gamma(\alpha)} (\beta(x - \zeta))^{\alpha-1} \exp(-\beta(x - \zeta))
\]

where:

\[
\beta = \frac{2}{\text{skewstddev}} \quad \alpha = (\text{stddev}\beta)^2 \zeta = \text{loc} - \frac{\alpha}{\beta}
\]

\texttt{pearson3} takes \text{skew} as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \text{loc} and \text{scale} parameters. Specifically, \texttt{pearson3.pdf(x, skew, loc, scale)} is identically equivalent to \texttt{pearson3.pdf(y, skew) / scale} with \(y = (x - \text{loc}) / \text{scale}\).

References

Examples

```python
>>> from scipy.stats import pearson3
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> skew = 0.1
>>> mean, var, skew, kurt = pearson3.stats(skew, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(pearson3.ppf(0.01, skew),
...                 pearson3.ppf(0.99, skew), 100)
>>> ax.plot(x, pearson3.pdf(x, skew),
...         'r-', lw=5, alpha=0.6, label='pearson3 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = pearson3(skew)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = pearson3.ppf([0.001, 0.5, 0.999], skew)
>>> np.allclose([0.001, 0.5, 0.999], pearson3.cdf(vals, skew))
True
```

Generate random numbers:
>>> r = pearson3.rvs(skew, size=1000)

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

```python
scipy.stats.powerlaw = <scipy.stats._continuous_distns.powerlaw_gen object>
```

A power-function continuous random variable.

As an instance of the `rv_continuous` class, `powerlaw` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `powerlaw` is:

\[
f(x, a) = ax^{a-1}
\]

for \(0 \leq x \leq 1, a > 0\).

`powerlaw` takes \(a\) as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `powerlaw.pdf(x, a, loc, scale)` is identically equivalent to `powerlaw.pdf(y, a) / scale` with \(y = (x - loc) / scale\).

`powerlaw` is a special case of `beta` with \(b == 1\).

**Examples**
>>> from scipy.stats import powerlaw
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

>>> a = 1.66
>>> mean, var, skew, kurt = powerlaw.stats(a, moments='mvsk')

Display the probability density function (pdf):

>>> x = np.linspace(powerlaw.ppf(0.01, a),
...                  powerlaw.ppf(0.99, a), 100)
>>> ax.plot(x, powerlaw.pdf(x, a),
...         'r-', lw=5, alpha=0.6, label='powerlaw pdf')

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

>>> rv = powerlaw(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')

Check accuracy of cdf and ppf:

>>> vals = powerlaw.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], powerlaw.cdf(vals, a))
True

Generate random numbers:

>>> r = powerlaw.rvs(a, size=1000)

And compare the histogram:

>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()

```
scipy.stats.powerlognorm = <scipy.stats._continuous_distns.powerlognorm_gen object>
```

A power log-normal continuous random variable.

As an instance of the `rv_continuous` class, `powerlognorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.
Notes
The probability density function for \texttt{powerlognorm} is:

\[
f(x, c, s) = \frac{c}{xs} \phi(\frac{\log(x)}{s}) \Phi(-\frac{\log(x)}{s})^{c-1}
\]

where \(\phi\) is the normal pdf, and \(\Phi\) is the normal cdf, and \(x > 0, s, c > 0\).

\texttt{powerlognorm} takes \(c\) and \(s\) as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \texttt{loc} and \texttt{scale} parameters. Specifically, \texttt{powerlognorm.pdf(x, c, s, loc, scale)} is identically equivalent to \texttt{powerlognorm.pdf(y, c, s) / scale} with \(y = (x - \texttt{loc}) / \texttt{scale}\).

Examples

```python
>>> from scipy.stats import powerlognorm
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> c, s = 2.14, 0.446
>>> mean, var, skew, kurt = powerlognorm.stats(c, s, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(powerlognorm.ppf(0.01, c, s),
...                  powerlognorm.ppf(0.99, c, s), 100)
>>> ax.plot(x, powerlognorm.pdf(x, c, s),
...         'r-', lw=5, alpha=0.6, label='powerlognorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = powerlognorm(c, s)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = powerlognorm.ppf([0.001, 0.5, 0.999], c, s)
>>> np.allclose([0.001, 0.5, 0.999], powerlognorm.cdf(vals, c, s))
True
```

Generate random numbers:

```python
>>> r = powerlognorm.rvs(c, s, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

`scipy.stats.powernorm = <scipy.stats._continuous_distns.powernorm_gen object>`

A power normal continuous random variable.

As an instance of the `rv_continuous` class, `powernorm` object inherits from it a collection of generic
methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for powernorm is:

\[ f(x, c) = c \phi(x)(\Phi(-x))^{c-1} \]

where \( \phi \) is the normal pdf, and \( \Phi \) is the normal cdf, and \( x > 0, c > 0 \).

powernorm takes \( c \) as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, powernorm.pdf(x, c, loc, scale) is identically equivalent to powernorm.pdf(y, c) / scale with \( y = (x - \text{loc}) / \text{scale} \).

Examples

```python
>>> from scipy.stats import powernorm
>>> import matplotlib.pyplot as plt

Calculate a few first moments:

```python
c = 4.45
>>> mean, var, skew, kurt = powernorm.stats(c, moments='mvsk')
```  
Display the probability density function (pdf):

```python
>>> x = np.linspace(powernorm.ppf(0.01, c), powernorm.ppf(0.99, c), 100)
>>> ax.plot(x, powernorm.pdf(x, c), 'r-', lw=5, alpha=0.6, label='powernorm pdf')
```  
Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = powernorm(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```  
Check accuracy of cdf and ppf:

```python
>>> vals = powernorm.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], powernorm.cdf(vals, c))
True
```  
Generate random numbers:

```python
>>> r = powernorm.rvs(c, size=1000)
```  
And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.rdist** = <scipy.stats._continuous_distns.rdist_gen object>

An R-distributed continuous random variable.

As an instance of the *rv_continuous* class, *rdist* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.
Notes

The probability density function for rdist is:

\[ f(x, c) = \frac{(1 - x^2)^{c/2-1}}{B(1/2, c/2)} \]

for \(-1 \leq x \leq 1, c > 0\).

rdist takes \(c\) as a shape parameter.

This distribution includes the following distribution kernels as special cases:

- \(c = 2\): uniform
- \(c = 4\): Epanechnikov (parabolic)
- \(c = 6\): quartic (biweight)
- \(c = 8\): triweight

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \(\text{loc}\) and \(\text{scale}\) parameters. Specifically, \(\text{rdist.pdf}(x, c, \text{loc}, \text{scale})\) is identically equivalent to \(\text{rdist.pdf}(y, c) / \text{scale}\) with \(y = (x - \text{loc}) / \text{scale}\).

Examples

```python
>>> from scipy.stats import rdist
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> c = 0.9
>>> mean, var, skew, kurt = rdist.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(rdist.ppf(0.01, c), rdist.ppf(0.99, c), 100)
>>> ax.plot(x, rdist.pdf(x, c), 'r-', lw=5, alpha=0.6, label='rdist pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = rdist(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = rdist.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], rdist.cdf(vals, c))
True
```

Generate random numbers:

```python
>>> r = rdist.rvs(c, size=1000)
```

And compare the histogram:
```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

```python
scipy.stats.reciprocal = <scipy.stats._continuous_distns.reciprocal_gen object>
```
A reciprocal continuous random variable.

As an instance of the `rv_continuous` class, `reciprocal` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability density function for `reciprocal` is:

\[ f(x, a, b) = \frac{1}{x \log(b/a)} \]

for \( a \leq x \leq b, \ a, \ b > 0 \).

`reciprocal` takes \( a \) and \( b \) as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `reciprocal.pdf(x, a, b, loc, scale)` is identically equivalent to `reciprocal.pdf(y, a, b) / scale` with \( y = (x - \text{loc}) / \text{scale} \).

**Examples**

```python
>>> from scipy.stats import reciprocal
>>> import matplotlib.pyplot as plt

fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> a, b = 0.00623, 1.01
>>> mean, var, skew, kurt = reciprocal.stats(a, b, moments='mvsk')
```  
Display the probability density function (pdf):

```python
>>> x = np.linspace(reciprocal.ppf(0.01, a, b),
...                  reciprocal.ppf(0.99, a, b), 100)
>>> ax.plot(x, reciprocal.pdf(x, a, b),
...          'r-', lw=5, alpha=0.6, label='reciprocal pdf')
```  
Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

**Freeze the distribution and display the frozen pdf:**

```python
>>> rv = reciprocal(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```  
Check accuracy of cdf and ppf:

```python
>>> vals = reciprocal.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], reciprocal.cdf(vals, a, b))
True
```  
Generate random numbers:

```python
>>> r = reciprocal.rvs(a, b, size=1000)
```  
And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.rayleigh = <scipy.stats._continuous_distns.rayleigh_gen object>**

A Rayleigh continuous random variable.

As an instance of the **rv_continuous** class, **rayleigh** object inherits from it a collection of generic meth-
ods (see below for the full list), and completes them with details specific for this particular distribution.

Notes
The probability density function for \texttt{rayleigh} is:

\[
f(r) = r \exp(-r^2/2)
\]

for \( x \geq 0 \).

\texttt{rayleigh} is a special case of \texttt{chi} with \( df == 2 \).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \texttt{loc} and \texttt{scale} parameters. Specifically, \texttt{rayleigh.pdf(x, loc, scale)} is identically equivalent to \texttt{rayleigh.pdf(y) / scale} with \( y = (x - \text{loc}) / \text{scale} \).

Examples

```python
>>> from scipy.stats import rayleigh
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> mean, var, skew, kurt = rayleigh.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(rayleigh.ppf(0.01),
...                 rayleigh.ppf(0.99), 100)
>>> ax.plot(x, rayleigh.pdf(x),
...          'r-', lw=5, alpha=0.6, label='rayleigh pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = rayleigh()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of \texttt{cdf} and \texttt{ppf}:

```python
>>> vals = rayleigh.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], rayleigh.cdf(vals))
True
```

Generate random numbers:

```python
>>> r = rayleigh.rvs(size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.rice = <scipy.stats._continuous_distns.rice_gen object>
A Rice continuous random variable.

As an instance of the rv_continuous class, rice object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.
Notes

The probability density function for \textit{rice} is:

\[ f(x, b) = x \exp\left(-\frac{x^2 + b^2}{2}\right) I_0(xb) \]

for \( x > 0, b > 0 \).

\textit{rice} takes \( b \) as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \textit{loc} and \textit{scale} parameters. Specifically, \textit{rice.pdf}(x, b, \textit{loc}, \textit{scale}) is identically equivalent to \textit{rice.pdf}(y, b) / \textit{scale} with \( y = (x - \textit{loc}) / \textit{scale} \).

The Rice distribution describes the length, \( r \), of a 2-D vector with components \((U + u, V + v)\), where \( U, V \) are constant, \( u, v \) are independent Gaussian random variables with standard deviation \( s \). Let \( R = \sqrt{U^2 + V^2} \). Then the pdf of \( r \) is \textit{rice.pdf}(x, \( R/s \), \textit{scale}=\( s \)).

Examples

```python
>>> from scipy.stats import rice
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> b = 0.775
>>> mean, var, skew, kurt = rice.stats(b, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(rice.ppf(0.01, b),
...                rice.ppf(0.99, b), 100)
>>> ax.plot(x, rice.pdf(x, b),
...          'r-', lw=5, alpha=0.6, label='rice pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = rice(b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = rice.ppf([0.001, 0.5, 0.999], b)
>>> np.allclose([0.001, 0.5, 0.999], rice.cdf(vals, b))
```

Generate random numbers:

```python
>>> r = rice.rvs(b, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```
Methods

- **rvs(b, loc=0, scale=1, size=1, random_state=None)**: Random variates.
- **pdf(x, b, loc=0, scale=1)**: Probability density function.
- **logpdf(x, b, loc=0, scale=1)**: Log of the probability density function.
- **cdf(x, b, loc=0, scale=1)**: Cumulative distribution function.
- **logcdf(x, b, loc=0, scale=1)**: Log of the cumulative distribution function.
- **sf(x, b, loc=0, scale=1)**: Survival function (also defined as 1 - cdf, but sf is sometimes more accurate).
- **logsf(x, b, loc=0, scale=1)**: Log of the survival function.
- **ppf(q, b, loc=0, scale=1)**: Percent point function (inverse of cdf — percentiles).
- **isf(q, b, loc=0, scale=1)**: Inverse survival function (inverse of sf).
- **moment(n, b, loc=0, scale=1)**: Non-central moment of order n.
- **stats(b, loc=0, scale=1, moments='mv')**: Mean(‘m’), variance(‘v’), skew(‘s’), and/or kurtosis(‘k’).
- **entropy(b, loc=0, scale=1)**: (Differential) entropy of the RV.
- **fit(data, b, loc=0, scale=1)**: Parameter estimates for generic data.
- **expect(func, args=(b,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)**: Expected value of a function (of one argument) with respect to the distribution.
- **median(b, loc=0, scale=1)**: Median of the distribution.
- **mean(b, loc=0, scale=1)**: Mean of the distribution.
- **var(b, loc=0, scale=1)**: Variance of the distribution.
- **std(b, loc=0, scale=1)**: Standard deviation of the distribution.
- **interval(alpha, b, loc=0, scale=1)**: Endpoints of the range that contains alpha percent of the distribution.

**scipy.stats.recipinvgauss = <scipy.stats._continuous_distns.recipinvgauss_gen object>**

A reciprocal inverse Gaussian continuous random variable.

As an instance of the rv_continuous class, recipinvgauss object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.
Notes

The probability density function for `recipinvgauss` is:

\[
f(x, \mu) = \frac{1}{\sqrt{2\pi x}} \exp\left(-\frac{(1 - \mu x)^2}{2x\mu^2}\right)
\]

for \( x \geq 0 \).

`recipinvgauss` takes \( \mu \) as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `recipinvgauss.pdf(x, \mu, \text{loc}, \text{scale})` is identically equivalent to `recipinvgauss.pdf(y, \mu) / \text{scale}` with \( y = (x - \text{loc}) / \text{scale} \).

Examples

```python
>>> from scipy.stats import recipinvgauss
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> mu = 0.63
>>> mean, var, skew, kurt = recipinvgauss.stats(mu, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(recipinvgauss.ppf(0.01, mu), ...
... recipinvgauss.ppf(0.99, mu), 100)
>>> ax.plot(x, recipinvgauss.pdf(x, mu), ...
... 'r-', lw=5, alpha=0.6, label='recipinvgauss pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = recipinvgauss(mu)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = recipinvgauss.ppf([0.001, 0.5, 0.999], mu)
>>> np.allclose([0.001, 0.5, 0.999], recipinvgauss.cdf(vals, mu))
True
```

Generate random numbers:

```python
>>> r = recipinvgauss.rvs(mu, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```
Methods

- **rvs**(mu, loc=0, scale=1, size=1, random_state=None)
  Random variates.
- **pdf**(x, mu, loc=0, scale=1)
  Probability density function.
- **logpdf**(x, mu, loc=0, scale=1)
  Log of the probability density function.
- **cdf**(x, mu, loc=0, scale=1)
  Cumulative distribution function.
- **logcdf**(x, mu, loc=0, scale=1)
  Log of the cumulative distribution function.
- **sf**(x, mu, loc=0, scale=1)
  Survival function (also defined as 1 - cdf, but sf is sometimes more accurate).
- **logsf**(x, mu, loc=0, scale=1)
  Log of the survival function.
- **ppf**(q, mu, loc=0, scale=1)
  Percent point function (inverse of cdf — percentiles).
- **isf**(q, mu, loc=0, scale=1)
  Inverse survival function (inverse of sf).
- **moment**(n, mu, loc=0, scale=1)
  Non-central moment of order n
- **stats**(mu, loc=0, scale=1, moments='mv')
  Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
- **entropy**(mu, loc=0, scale=1)
  (Differential) entropy of the RV.
- **fit**(data, mu, loc=0, scale=1)
  Parameter estimates for generic data.
- **expect**(func, args=(mu,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)
  Expected value of a function (of one argument) with respect to the distribution.
- **median**(mu, loc=0, scale=1)
  Median of the distribution.
- **mean**(mu, loc=0, scale=1)
  Mean of the distribution.
- **var**(mu, loc=0, scale=1)
  Variance of the distribution.
- **std**(mu, loc=0, scale=1)
  Standard deviation of the distribution.
- **interval**(alpha, mu, loc=0, scale=1)
  Endpoints of the range that contains alpha percent of the distribution.

```
scipy.stats.semicircular = <scipy.stats._continuous_distns.semicircular_gen object>
```
A semicircular continuous random variable.

As an instance of the **rv_continuous** class, semicircular object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.
Notes

The probability density function for semicircular is:

\[ f(x) = \frac{2}{\pi} \sqrt{1 - x^2} \]

for \(-1 \leq x \leq 1\).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, \(\text{semicircular.pdf}(x, \text{loc}, \text{scale})\) is identically equivalent to \(\text{semicircular.pdf}(y) / \text{scale}\) with \(y = (x - \text{loc}) / \text{scale}\).

Examples

```python
>>> from scipy.stats import semicircular
>>> import matplotlib.pyplot as plt

fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> mean, var, skew, kurt = semicircular.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(semicircular.ppf(0.01), ...
...                 semicircular.ppf(0.99), 100)
>>> ax.plot(x, semicircular.pdf(x), ...
...          'r-', lw=5, alpha=0.6, label='semicircular pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = semicircular()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = semicircular.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], semicircular.cdf(vals))
```

Generate random numbers:

```python
>>> r = semicircular.rvs(size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.skewnorm = <scipy.stats._continuous_distns.skew_norm_gen object>**

A skew-normal random variable.

As an instance of the `rv_continuous` class, `skewnorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.
### Notes

The pdf is:

\[
\text{skewnorm.pdf}(x, a) = 2 \times \text{norm.pdf}(x) \times \text{norm.cdf}(a \times x)
\]

`skewnorm` takes \(a\) as a skewness parameter. When \(a = 0\) the distribution is identical to a normal distribution. `rvs` implements the method of [R697].

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `skewnorm.pdf(x, a, loc, scale)` is identically equivalent to `skewnorm.pdf(y, a) / scale` with \(y = (x - \text{loc}) / \text{scale}\).

### References

[R697]

### Examples

```python
>>> from scipy.stats import skewnorm
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> a = 4
>>> mean, var, skew, kurt = skewnorm.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(skewnorm.ppf(0.01, a),
>>>                  skewnorm.ppf(0.99, a), 100)
>>> ax.plot(x, skewnorm.pdf(x, a),
>>>         'r-', lw=5, alpha=0.6, label='skewnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = skewnorm(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = skewnorm.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], skewnorm.cdf(vals, a))
```

Generate random numbers:

```python
>>> r = skewnorm.rvs(a, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.t = <scipy.stats._continuous_distns.t_gen object>

A Student’s T continuous random variable.

As an instance of the rv_continuous class, t object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.
Notes

The probability density function for \( t \) is:

\[
    f(x, df) = \frac{\gamma((df + 1)/2)}{\sqrt{\pi} \cdot df \gamma(df/2)(1 + x^2/df)^{(df+1)/2}}
\]

for \( df > 0 \).

\( t \) takes \( df \) as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \( \text{loc} \) and \( \text{scale} \) parameters. Specifically, \( t.pdf(x, df, \text{loc}, \text{scale}) \) is identically equivalent to \( t.pdf(y, df) / \text{scale} \) with \( y = (x - \text{loc}) / \text{scale} \).

Examples

```python
>>> from scipy.stats import t
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> df = 2.74
>>> mean, var, skew, kurt = t.stats(df, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(t.ppf(0.01, df), ...
...                  t.ppf(0.99, df), 100)
>>> ax.plot(x, t.pdf(x, df), ...
...          'r-', lw=5, alpha=0.6, label='t pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = t(df)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = t.ppf([0.001, 0.5, 0.999], df)
>>> np.allclose([0.001, 0.5, 0.999], t.cdf(vals, df))
```

Generate random numbers:

```python
>>> r = t.rvs(df, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

#### scipy.stats.trapz

A trapezoidal continuous random variable.

As an instance of the `rv_continuous` class, `trapz` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.
Notes

The trapezoidal distribution can be represented with an up-sloping line from $\text{loc}$ to $(\text{loc} + c \times \text{scale})$, then constant to $(\text{loc} + d \times \text{scale})$ and then downsloping from $(\text{loc} + d \times \text{scale})$ to $(\text{loc} + \text{scale})$.

$\text{trapz}$ takes $c$ and $d$ as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the $\text{loc}$ and $\text{scale}$ parameters. Specifically, $\text{trapz.pdf}(x, c, d, \text{loc, scale})$ is identically equivalent to $\text{trapz.pdf}(y, c, d) / \text{scale}$ with $y = (x - \text{loc}) / \text{scale}$.

The standard form is in the range $[0, 1]$ with $c$ the mode. The location parameter shifts the start to $\text{loc}$. The scale parameter changes the width from 1 to $\text{scale}$.

Examples

```python
>>> from scipy.stats import trapz
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

>>> c, d = 0.2, 0.8
>>> mean, var, skew, kurt = trapz.stats(c, d, moments='mvsk')

>>> x = np.linspace(trapz.ppf(0.01, c, d), ... trapz.ppf(0.99, c, d), 100)
>>> ax.plot(x, trapz.pdf(x, c, d), ... 'r-', lw=5, alpha=0.6, label='trapz pdf')

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = trapz(c, d)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of $\text{cdf}$ and $\text{ppf}$:

```python
>>> vals = trapz.ppf([0.001, 0.5, 0.999], c, d)
>>> np.allclose([0.001, 0.5, 0.999], trapz.cdf(vals, c, d))
True
```

Generate random numbers:

```python
>>> r = trapz.rvs(c, d, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.triang = <scipy.stats._continuous_distns.triang_gen object>

A triangular continuous random variable.

As an instance of the rv_continuous class, triang object inherits from it a collection of generic methods
(see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The triangular distribution can be represented with an up-sloping line from \( \text{loc} \) to \((\text{loc} + c \times \text{scale})\) and then downsloping for \((\text{loc} + c \times \text{scale})\) to \((\text{loc} + \text{scale})\).

\texttt{triang} takes \(c\) as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \texttt{loc} and \texttt{scale} parameters. Specifically, \texttt{triang.pdf(\(x\), \(c\), \texttt{loc}, \texttt{scale})} is identically equivalent to \texttt{triang.pdf(\(y\), \(c\)) / scale} with \(y = (x - \text{loc}) / \text{scale}\).

The standard form is in the range \([0, 1]\) with \(c\) the mode. The location parameter shifts the start to \(\text{loc}\). The scale parameter changes the width from 1 to \(\text{scale}\).

**Examples**

```python
>>> from scipy.stats import triang
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

>>> c = 0.158

>>> mean, var, skew, kurt = triang.stats(c, moments='mvsk')

Display the probability density function (pdf):

```python
>>> x = np.linspace(triang.ppf(0.01, c),
...                 triang.ppf(0.99, c), 100)
```  

>>> ax.plot(x, triang.pdf(x, c),
...          'r-', lw=5, alpha=0.6, label='triang pdf')

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = triang(c)

>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = triang.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], triang.cdf(vals, c))
True

Generate random numbers:

```python
>>> r = triang.rvs(c, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.truncexpon = <scipy.stats._continuous_distns.truncexpon_gen object>

A truncated exponential continuous random variable.

As an instance of the rv_continuous class, truncexpon object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.
Notes

The probability density function for \texttt{truncexpon} is:

\[ f(x, b) = \frac{\exp(-x)}{1 - \exp(-b)} \]

for \(0 < x < b\).

\texttt{truncexpon} takes \(b\) as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \texttt{loc} and \texttt{scale} parameters. Specifically, \texttt{truncexpon.pdf(x, b, loc, scale)} is identically equivalent to \texttt{truncexpon.pdf(y, b) / scale} with \(y = (x - \texttt{loc}) / \texttt{scale}\).

Examples

```python
>>> from scipy.stats import truncexpon
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> b = 4.69
>>> mean, var, skew, kurt = truncexpon.stats(b, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(truncexpon.ppf(0.01, b),
... truncexpon.ppf(0.99, b), 100)
>>> ax.plot(x, truncexpon.pdf(x, b),
... 'r-', lw=5, alpha=0.6, label='truncexpon pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = truncexpon(b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = truncexpon.ppf([0.001, 0.5, 0.999], b)
>>> np.allclose([0.001, 0.5, 0.999], truncexpon.cdf(vals, b))
True
```

Generate random numbers:

```python
>>> r = truncexpon.rvs(b, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.truncnorm = <scipy.stats._continuous_distns.truncnorm_gen object>

A truncated normal continuous random variable.

As an instance of the rv_continuous class, truncnorm object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.
Notes

The standard form of this distribution is a standard normal truncated to the range \([a, b]\) — notice that \(a\) and \(b\) are defined over the domain of the standard normal. To convert clip values for a specific mean and standard deviation, use:

\[
a, b = (\text{myclip}_a - \text{my_mean}) / \text{my_std}, (\text{myclip}_b - \text{my_mean}) / \text{my_std}
\]

`truncnorm` takes \(a\) and \(b\) as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `truncnorm.pdf(x, a, b, loc, scale)` is identically equivalent to `truncnorm.pdf(y, a, b) / scale` with \(y = (x - \text{loc}) / \text{scale}\).

Examples

```python
>>> from scipy.stats import truncnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> a, b = 0.1, 2
>>> mean, var, skew, kurt = truncnorm.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(truncnorm.ppf(0.01, a, b),
... truncnorm.ppf(0.99, a, b), 100)
>>> ax.plot(x, truncnorm.pdf(x, a, b),
... 'r-', lw=5, alpha=0.6, label='truncnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = truncnorm(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

```python
>>> vals = truncnorm.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], truncnorm.cdf(vals, a, b))
True
```

Generate random numbers:

```python
>>> r = truncnorm.rvs(a, b, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats.tukeylambda** = <scipy.stats._continuous_distns.tukeylambda_gen object>

A Tukey-Lamdba continuous random variable.

As an instance of the **rv_continuous** class, tukeylambda object inherits from it a collection of generic
methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

A flexible distribution, able to represent and interpolate between the following distributions:

- Cauchy (lam=-1)
- logistic (lam=0.0)
- approx Normal (lam=0.14)
- u-shape (lam = 0.5)
- uniform from -1 to 1 (lam = 1)

`tukeylambda` takes `lam` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `tukeylambda.pdf(x, lam, loc, scale)` is identically equivalent to `tukeylambda.pdf(y, lam) / scale` with `y = (x - loc) / scale`.

Examples

```python
>>> from scipy.stats import tukeylambda
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)
>>> lam = 3.13
>>> mean, var, skew, kurt = tukeylambda.stats(lam, moments='mvsk')

Calculate a few first moments:

```python
>>> mean, var, skew, kurt = tukeylambda.stats(lam, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(tukeylambda.ppf(0.01, lam),
...     tukeylambda.ppf(0.99, lam), 100)
>>> ax.plot(x, tukeylambda.pdf(x, lam), 'r-', lw=5, alpha=0.6, label='tukeylambda pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = tukeylambda(lam)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = tukeylambda.ppf([0.001, 0.5, 0.999], lam)
>>> np.allclose([0.001, 0.5, 0.999], tukeylambda.cdf(vals, lam))
True
```

Generate random numbers:

```python
>>> r = tukeylambda.rvs(lam, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```
Methods

rvs(lam, loc=0, scale=1, size=1, random_state=None)  Random variates.
pdf(x, lam, loc=0, scale=1)  Probability density function.
logpdf(x, lam, loc=0, scale=1)  Log of the probability density function.
cdf(x, lam, loc=0, scale=1)  Cumulative distribution function.
logcdf(x, lam, loc=0, scale=1)  Log of the cumulative distribution function.
sf(x, lam, loc=0, scale=1)  Survival function (also defined as 1 - cdf, but sf is sometimes more accurate).
logsf(x, lam, loc=0, scale=1)  Log of the survival function.
ppf(q, lam, loc=0, scale=1)  Percent point function (inverse of cdf — percentiles).
iscf(q, lam, loc=0, scale=1)  Inverse survival function (inverse of sf).
moment(n, lam, loc=0, scale=1)  Non-central moment of order n
stats(lam, loc=0, scale=1, moments='mv')  Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(lam, loc=0, scale=1)  (Differential) entropy of the RV.
fit(data, lam, loc=0, scale=1)  Parameter estimates for generic data.
expect(func, args=(lam,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)  Expected value of a function (of one argument) with respect to the distribution.
median(lam, loc=0, scale=1)  Median of the distribution.
mean(lam, loc=0, scale=1)  Mean of the distribution.
var(lam, loc=0, scale=1)  Variance of the distribution.
std(lam, loc=0, scale=1)  Standard deviation of the distribution.
interval(alpha, lam, loc=0, scale=1)  Endpoints of the range that contains alpha percent of the distribution

scipy.stats.unifom = <scipy.stats._continuous_distns.uniform_gen object>
A uniform continuous random variable.

This distribution is constant between loc and loc + scale.
As an instance of the `rv_continuous` class, `uniform` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Examples**

```python
>>> from scipy.stats import uniform
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```python
>>> mean, var, skew, kurt = uniform.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(uniform.ppf(0.01),
...                 uniform.ppf(0.99), 100)
>>> ax.plot(x, uniform.pdf(x),
...         'r-', lw=5, alpha=0.6, label='uniform pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = uniform()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = uniform.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], uniform.cdf(vals))
True
```

Generate random numbers:

```python
>>> r = uniform.rvs(size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

```python
scipy.stats.vonmises = <scipy.stats._continuous_distns.vonmises_gen object>
```

A Von Mises continuous random variable.

As an instance of the `rv_continuous` class, `vonmises` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.
See also:

`vonmises_line`

The same distribution, defined on a [-pi, pi] segment of the real line.

Notes

If x is not in range or loc is not in range it assumes they are angles and converts them to [-pi, pi] equivalents.

The probability density function for `vonmises` is:

\[
    f(x, \kappa) = \frac{\exp(\kappa \cos(x))}{2\pi I_0(\kappa)}
\]

for \(-\pi \leq x \leq \pi, \kappa > 0\).

`vonmises` takes \(\kappa\) as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, `vonmises.pdf(x, kappa, loc, scale)` is identically equivalent to `vonmises.pdf(y, kappa) / scale` with \(y = (x - loc) / scale\).

Examples

```python
>>> from scipy.stats import vonmises
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> kappa = 3.99
>>> mean, var, skew, kurt = vonmises.stats(kappa, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(vonmises.ppf(0.01, kappa), ...
...                   vonmises.ppf(0.99, kappa), 100)
>>> ax.plot(x, vonmises.pdf(x, kappa), ...
...         'r-', lw=5, alpha=0.6, label='vonmises pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed. Freeze the distribution and display the frozen pdf:

```python
>>> rv = vonmises(kappa)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = vonmises.ppf([0.001, 0.5, 0.999], kappa)
>>> np.allclose([0.001, 0.5, 0.999], vonmises.cdf(vals, kappa))
True
```

Generate random numbers:

```python
>>> r = vonmises.rvs(kappa, size=1000)
```

And compare the histogram:
```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

5.27. Statistical functions (`scipy.stats`) 1909
Examples

```python
>>> from scipy.stats import vonmises_line
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> kappa = 3.99
>>> mean, var, skew, kurt = vonmises_line.stats(kappa, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(vonmises_line.ppf(0.01, kappa), ...
... vonmises_line.ppf(0.99, kappa), 100)
>>> ax.plot(x, vonmises_line.pdf(x, kappa), ...
... 'r-', lw=5, alpha=0.6, label='vonmises_line pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = vonmises_line(kappa)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = vonmises_line.ppf([0.001, 0.5, 0.999], kappa)
>>> np.allclose([0.001, 0.5, 0.999], vonmises_line.cdf(vals, kappa))
True
```

Generate random numbers:

```python
>>> r = vonmises_line.rvs(kappa, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.wald = <scipy.stats._continuous_distns.wald_gen object>

A Wald continuous random variable.

As an instance of the rv_continuous class, wald object inherits from it a collection of generic methods
The probability density function for wald is:

\[
f(x) = \frac{1}{\sqrt{2\pi x^3}} \exp\left(-\frac{(x - 1)^2}{2x}\right)
\]

for \( x > 0 \).

wald is a special case of invgauss with \( \mu = 1 \).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, wald.pdf\( (x, \text{loc}, \text{scale}) \) is identically equivalent to wald.pdf\( (y) / \text{scale} \) with \( y = (x - \text{loc}) / \text{scale} \).

**Examples**

```python
>>> from scipy.stats import wald
>>> import matplotlib.pyplot as plt

Calculate a few first moments:

```python
>>> mean, var, skew, kurt = wald.stats(moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(wald.ppf(0.01), ...
... wald.ppf(0.99), 100)
>>> ax.plot(x, wald.pdf(x), ...
... 'r-', lw=5, alpha=0.6, label='wald pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = wald()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = wald.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], wald.cdf(vals))
```

Generate random numbers:

```python
>>> r = wald.rvs(size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

**scipy.stats. weibull_min = <scipy.stats._continuous_distns.weibull_min_gen object>**

Weibull minimum continuous random variable.

As an instance of the rv_continuous class, weibull_min object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.
See also:

weibull_max

Notes

The probability density function for \texttt{weibull_min} is:

\[ f(x, c) = cx^{c-1} \exp(-x^c) \]

for \( x > 0, c > 0 \).

\texttt{weibull_min} takes \( c \) as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \texttt{loc} and \texttt{scale} parameters. Specifically, \texttt{weibull_min.pdf}(x, c, \texttt{loc}, \texttt{scale}) is identically equivalent to \texttt{weibull_min.pdf}(y, c) / \texttt{scale} with \( y = (x - \texttt{loc}) / \texttt{scale} \).

Examples

```python
>>> from scipy.stats import weibull_min
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> c = 1.79
>>> mean, var, skew, kurt = weibull_min.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(weibull_min.ppf(0.01, c), ...
... weibull_min.ppf(0.99, c), 100)
>>> ax.plot(x, weibull_min.pdf(x, c), ...
... 'r-', lw=5, alpha=0.6, label='weibull_min pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = weibull_min(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = weibull_min.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], weibull_min.cdf(vals, c))
True
```

Generate random numbers:

```python
>>> r = weibull_min.rvs(c, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```
Weibull minimum continuous random variable.

As an instance of the `rv_continuous` class, `weibull_min` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.
See also:

weibull_min

Notes

The probability density function for weibull_max is:

\[ f(x, c) = c(-x)^{c-1} \exp(-(-x)^c) \]

for \( x < 0, c > 0 \).

weibull_max takes \( c \) as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the \( \text{loc} \) and \( \text{scale} \) parameters. Specifically, \( \text{weibull_max.pdf}(x, c, \text{loc}, \text{scale}) \) is identically equivalent to \( \text{weibull_max.pdf}(y, c) / \text{scale} \) with \( y = (x - \text{loc}) / \text{scale} \).

Examples

```python
>>> from scipy.stats import weibull_max
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
c = 2.87
>>> mean, var, skew, kurt = weibull_max.stats(c, moments='mvsk')
```  
Display the probability density function (pdf):

```python
>>> x = np.linspace(weibull_max.ppf(0.01, c),
...                  weibull_max.ppf(0.99, c), 100)
>>> ax.plot(x, weibull_max.pdf(x, c),
...          'r-', lw=5, alpha=0.6, label='weibull_max pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = weibull_max(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = weibull_max.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], weibull_max.cdf(vals, c))
True
```

Generate random numbers:

```python
>>> r = weibull_max.rvs(c, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.wrapcauchy = <scipy.stats._continuous_distns.wrapcauchy_gen object>  
A wrapped Cauchy continuous random variable.

As an instance of the rv_continuous class, wrapcauchy object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.
Notes
The probability density function for wrapcauchy is:

\[ f(x, c) = \frac{1 - c^2}{2\pi(1 + c^2 - 2c\cos(x))} \]

for \(0 \leq x \leq 2\pi, 0 < c < 1\).

wrapcauchy takes \(c\) as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the loc and scale parameters. Specifically, wrapcauchy.pdf\((x, c, \text{loc, scale})\) is identically equivalent to wrapcauchy.pdf\((y, c) / \text{scale}\) with \(y = (x - \text{loc}) / \text{scale}\).

Examples

```python
>>> from scipy.stats import wrapcauchy
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> c = 0.0311
>>> mean, var, skew, kurt = wrapcauchy.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```python
>>> x = np.linspace(wrapcauchy.ppf(0.01, c), ... wrapcauchy.ppf(0.99, c), 100)
>>> ax.plot(x, wrapcauchy.pdf(x, c), ... 'r-', lw=5, alpha=0.6, label='wrapcauchy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```python
>>> rv = wrapcauchy(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```python
>>> vals = wrapcauchy.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], wrapcauchy.cdf(vals, c))
```
True

Generate random numbers:

```python
>>> r = wrapcauchy.rvs(c, size=1000)
```

And compare the histogram:

```python
>>> ax.hist(r, normed=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

5.27.2 Multivariate distributions
The mean keyword specifies the mean. The cov keyword specifies the covariance matrix.

Parameters

- **x**: array_like
  Quantiles, with the last axis of x denoting the components.
- **mean**: array_like, optional
  Mean of the distribution (default zero)
- **cov**: array_like, optional
  Covariance matrix of the distribution (default one)
- **allow_singular**: bool, optional
  Whether to allow a singular covariance matrix. (Default: False)
- **random_state**: None or int or np.random.RandomState instance, optional
  If int or RandomState, use it for drawing the random variates. If None (or np.random), the global np.random state is used. Default is None.

Alternatively, the object may be called (as a function) to fix the mean and covariance parameters, returning a “frozen” multivariate normal random variable:

```python
rv = multivariate_normal(mean=None, cov=1, allow_singular=False)
```

*Frozen object with the same methods but holding the given mean and covariance fixed.*

Notes

**Setting the parameter mean to None is equivalent to having mean**

be the zero-vector. The parameter cov can be a scalar, in which case the covariance matrix is the identity times that value, a vector of diagonal entries for the covariance matrix, or a two-dimensional array_like.

The covariance matrix cov must be a (symmetric) positive semi-definite matrix. The determinant and inverse of cov are computed as the pseudo-determinant and pseudo-inverse, respectively, so that cov does not need to have full rank.

The probability density function for multivariate_normal is

\[
f(x) = \frac{1}{\sqrt{(2\pi)^k \det \Sigma}} \exp \left( -\frac{1}{2} (x - \mu)^T \Sigma^{-1} (x - \mu) \right),
\]

where \(\mu\) is the mean, \(\Sigma\) the covariance matrix, and \(k\) is the dimension of the space where \(x\) takes values.

New in version 0.14.0.
Examples

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.stats import multivariate_normal

>>> x = np.linspace(0, 5, 10, endpoint=False)
>>> y = multivariate_normal.pdf(x, mean=2.5, cov=0.5); y
array([ 0.00108914, 0.01033349, 0.05846514, 0.20755375, 0.43939129,
        0.56418958, 0.43939129, 0.20755375, 0.05846514, 0.01033349])
>>> fig1 = plt.figure()
>>> ax = fig1.add_subplot(111)
>>> ax.plot(x, y)
```

The input quantiles can be any shape of array, as long as the last axis labels the components. This allows us for instance to display the frozen pdf for a non-isotropic random variable in 2D as follows:

```python
>>> x, y = np.mgrid[-1:1:.01, -1:1:.01]
>>> pos = np.dstack((x, y))
>>> rv = multivariate_normal([0.5, -0.2], [[2.0, 0.3], [0.3, 0.5]])
>>> fig2 = plt.figure()
>>> ax2 = fig2.add_subplot(111)
>>> ax2.contourf(x, y, rv.pdf(pos))
```

\texttt{scipy.stats.matrix_normal} = \texttt{<scipy.stats._multivariate.matrix_normal_gen object>}

A matrix normal random variable.

The \texttt{mean} keyword specifies the mean. The \texttt{rowcov} keyword specifies the among-row covariance matrix. The \texttt{colcov} keyword specifies the among-column covariance matrix.

**Parameters**

- \texttt{X} : array_like
  - Quantiles, with the last two axes of \( X \) denoting the components.
- \texttt{mean} : array_like, optional
  - Mean of the distribution (default: \texttt{None})
- \texttt{rowcov} : array_like, optional
  - Among-row covariance matrix of the distribution (default: \( I \))
- \texttt{colcov} : array_like, optional
  - Among-column covariance matrix of the distribution (default: \( I \))
- \texttt{random_state} : None or int or np.random.RandomState instance, optional
  - If int or RandomState, use it for drawing the random variates. If None (or np.random), the global np.random state is used. Default is None.

Alternatively, the object may be called (as a function) to fix the mean and covariance parameters, returning a “frozen” matrix normal.
random variable:
\[ \text{rv} = \text{matrix\_normal} \text{(mean=None, rowcov=1, colcov=1)} \]

- Frozen object with the same methods but holding the given mean and covariance fixed.

**Notes**

*If mean is set to None then a matrix of zeros is used for the mean.*

The dimensions of this matrix are inferred from the shape of `rowcov` and `colcov`, if these are provided, or set to 1 if ambiguous.

`rowcov` and `colcov` can be two-dimensional array_likes specifying the covariance matrices directly. Alternatively, a one-dimensional array will be be interpreted as the entries of a diagonal matrix, and a scalar or zero-dimensional array will be interpreted as this value times the identity matrix.

The covariance matrices specified by `rowcov` and `colcov` must be (symmetric) positive definite. If the samples in \( X \) are \( m \times n \), then `rowcov` must be \( m \times m \) and `colcov` must be \( n \times n \). `mean` must be the same shape as \( X \).

The probability density function for `matrix\_normal` is

\[
f(X) = (2\pi)^{-\frac{m+n}{2}} |U|^{-\frac{m}{2}} |V|^{-\frac{n}{2}} \exp \left( -\frac{1}{2} \text{Tr} \left[ U^{-1}(X - M) V^{-1} (X - M)^T \right] \right),
\]

where \( M \) is the mean, \( U \) the among-row covariance matrix, \( V \) the among-column covariance matrix.

The `allow\_singular` behaviour of the `multivariate\_normal` distribution is not currently supported. Covariance matrices must be full rank.

The `matrix\_normal` distribution is closely related to the `multivariate\_normal` distribution. Specifically, \( \text{Vec}(X) \) (the vector formed by concatenating the columns of \( X \)) has a multivariate normal distribution with mean \( \text{Vec}(M) \) and covariance \( V \otimes U \) (where \( \otimes \) is the Kronecker product). Sampling and pdf evaluation are \( O(m^3 + n^3 + m^2n + mn^2) \) for the matrix normal, but \( O(m^3n^3) \) for the equivalent multivariate normal, making this equivalent form algorithmically inefficient.

New in version 0.17.0.

**Examples**

```python
>>> from scipy.stats import matrix_normal
>>> M = np.arange(6).reshape(3,2); M
array([[0, 1],
       [2, 3],
       [4, 5]])
>>> U = np.diag([1,2,3]); U
array([[1, 0, 0],
       [0, 2, 0],
       [0, 0, 3]])
>>> V = 0.3*np.identity(2); V
array([[ 0.3, 0. ],
       [ 0. , 0.3]])
>>> X = M + 0.1; X
array([[ 0.1, 1.1],
       [ 2.1, 3.1],
       [ 4.1, 5.1]])
>>> matrix_normal.pdf(X, mean=M, rowcov=U, colcov=V)
0.023410202050005054
```
```python
>>> # Equivalent multivariate normal
>>> from scipy.stats import multivariate_normal
>>> vectorised_X = X.T.flatten()
>>> equiv_mean = M.T.flatten()
>>> equiv_cov = np.kron(V,U)
>>> multivariate_normal.pdf(vectorised_X, mean=equiv_mean, cov=equiv_cov)
0.023410202050005054
```

#### scipy.stats.dirichlet = <scipy.stats._multivariate.dirichlet_gen object>

A Dirichlet random variable.

The `alpha` keyword specifies the concentration parameters of the distribution.

New in version 0.15.0.

**Parameters**

- `x`: array_like
  - Quantiles, with the last axis of `x` denoting the components.
- `alpha`: array_like
  - The concentration parameters. The number of entries determines the dimensionality of the distribution.
- `random_state`: None or int or np.random.RandomState instance, optional
  - If int or RandomState, use it for drawing the random variates. If None (or np.random), the global np.random state is used. Default is None.

Alternatively, the object may be called (as a function) to fix concentration parameters, returning a “frozen” Dirichlet random variable:

```python
rv = dirichlet(alpha)
```
- *Frozen object with the same methods but holding the given concentration parameters fixed.*

**Notes**

Each `α` entry must be positive. The distribution has only support on the simplex defined by

\[
\sum_{i=1}^{K} x_i \leq 1
\]

The probability density function for `dirichlet` is

\[
f(x) = \frac{1}{B(\alpha)} \prod_{i=1}^{K} x_i^{\alpha_i - 1}
\]

where

\[
B(\alpha) = \frac{\prod_{i=1}^{K} \Gamma(\alpha_i)}{\Gamma(\sum_{i=1}^{K} \alpha_i)}
\]

and \(\alpha = (\alpha_1, \ldots, \alpha_K)\), the concentration parameters and \(K\) is the dimension of the space where \(x\) takes values.

Note that the dirichlet interface is somewhat inconsistent. The array returned by the rvs function is transposed with respect to the format expected by the pdf and logpdf.

`scipy.stats.wishart = <scipy.stats._multivariate.wishart_gen object>`

A Wishart random variable.

The `df` keyword specifies the degrees of freedom. The `scale` keyword specifies the scale matrix, which must be symmetric and positive definite. In this context, the scale matrix is often interpreted in terms of a multivariate normal precision matrix (the inverse of the covariance matrix).

**Parameters**

- `x`: array_like
  Quantiles, with the last axis of `x` denoting the components.
- `df`: int
  Degrees of freedom, must be greater than or equal to dimension of the scale matrix.
- `scale`: array_like
  Symmetric positive definite scale matrix of the distribution.
- `random_state`: None or int or np.random.RandomState instance, optional
  If int or RandomState, use it for drawing the random variates. If None (or np.random), the global np.random state is used. Default is None.

Alternatively, the object may be called (as a function) to fix the degrees of freedom and scale parameters, returning a “frozen” Wishart random variable:

```
rw = wishart(df=1, scale=1)
```

- Frozen object with the same methods but holding the given degrees of freedom and scale fixed.

**See also:**

`invwishart, chi2`

**Notes**

The scale matrix `scale` must be a symmetric positive definite matrix. Singular matrices, including the symmetric positive semi-definite case, are not supported.

The Wishart distribution is often denoted

\[ W_p(\nu, \Sigma) \]

where \( \nu \) is the degrees of freedom and \( \Sigma \) is the \( p \times p \) scale matrix.

The probability density function for `wishart` has support over positive definite matrices `S`; if \( S \sim W_p(\nu, \Sigma) \), then its PDF is given by:

\[
f(S) = \frac{|S|^{\frac{\nu-p-1}{2}}}{2^{\frac{p(p+1)}{4}} |\Sigma|^{\frac{p}{2}} \Gamma_p \left(\frac{p}{2}\right)} \exp \left(-tr(S^{-1}\Sigma)/2\right)
\]

If \( S \sim W_p(\nu, \Sigma) \) (Wishart) then \( S^{-1} \sim W_p^{-1}(\nu, \Sigma^{-1}) \) (inverse Wishart).

If the scale matrix is 1-dimensional and equal to one, then the Wishart distribution \( W_1(\nu, 1) \) collapses to the \( \chi^2(\nu) \) distribution.
New in version 0.16.0.

References

[R716], [R717]

Examples

```python
>>> import matplotlib.pyplot as plt
>>> from scipy.stats import wishart, chi2

>>> x = np.linspace(1e-5, 8, 100)

>>> w = wishart.pdf(x, df=3, scale=1); w[:5]
array([ 0.00126156, 0.10892176, 0.14793434, 0.17400548, 0.19296690])

>>> c = chi2.pdf(x, 3); c[:5]
array([ 0.00126156, 0.10892176, 0.14793434, 0.17400548, 0.19296690])

>>> plt.plot(x, w)
```

The input quantiles can be any shape of array, as long as the last axis labels the components.

`scipy.stats.invwishart = <scipy.stats._multivariate.invwishart_gen object>`

An inverse Wishart random variable.

The `df` keyword specifies the degrees of freedom. The `scale` keyword specifies the scale matrix, which must be symmetric and positive definite. In this context, the scale matrix is often interpreted in terms of a multivariate normal covariance matrix.

Parameters

- `x`: array_like
  - Quantiles, with the last axis of `x` denoting the components.
- `df`: int
Degrees of freedom, must be greater than or equal to dimension of the scale matrix

scale : array_like
    Symmetric positive definite scale matrix of the distribution

random_state : None or int or np.random.RandomState instance, optional
    If int or RandomState, use it for drawing the random variates. If None (or np.random), the global np.random state is used. Default is None.

Alternatively, the object may be called (as a function) to fix the degrees of freedom and scale parameters, returning a “frozen” inverse Wishart random variable:
rv = invwishart(df=1, scale=1)

• Frozen object with the same methods but holding the given degrees of freedom and scale fixed.

See also:

wishart

Notes

The scale matrix scale must be a symmetric positive definite matrix. Singular matrices, including the symmetric positive semi-definite case, are not supported.

The inverse Wishart distribution is often denoted \( W^{-1}_p(\nu, \Psi) \)

where \( \nu \) is the degrees of freedom and \( \Psi \) is the \( p \times p \) scale matrix.

The probability density function for invwishart has support over positive definite matrices \( S \); if \( S \sim W^{-1}_p(\nu, \Sigma) \), then its PDF is given by:

\[
f(S) = \frac{|\Sigma|^{\frac{\nu}{2}}}{2^{\frac{\nu p}{2}} |S|^{\frac{\nu p + p + 1}{2}} \Gamma_p \left( \frac{\nu}{2} \right)} \exp \left( -tr(\Sigma S^{-1})/2 \right)
\]

If \( S \sim W^{-1}_p(\nu, \Psi) \) (inverse Wishart) then \( S^{-1} \sim W_p(\nu, \Psi^{-1}) \) (Wishart).

If the scale matrix is 1-dimensional and equal to one, then the inverse Wishart distribution \( W_1(\nu, 1) \) collapses to the inverse Gamma distribution with parameters shape = \( \frac{\nu}{2} \) and scale = \( \frac{1}{2} \).

New in version 0.16.0.

```python
scipy.stats.multinomial = <scipy.stats_multivariate.multinomial_gen object>
```

A multinomial random variable.

**Parameters**

- `x`: array_like
  Quantiles, with the last axis of `x` denoting the components.
- `n`: int
  Number of trials
- `p`: array_like
  Probability of a trial falling into each category; should sum to 1
- `random_state`: None or int or np.random.RandomState instance, optional
  If int or RandomState, use it for drawing the random variates. If None (or np.random), the global np.random state is used. Default is None.

**See also:**

- `scipy.stats.binom`
  The binomial distribution.
- `numpy.random.multinomial`
  Sampling from the multinomial distribution.

**Notes**

- `n` should be a positive integer. Each element of `p` should be in the interval [0, 1] and the elements should sum to 1. If they do not sum to 1, the last element of the `p` array is not used and is replaced with the remaining probability left over from the earlier elements.

Alternatively, the object may be called (as a function) to fix the `n` and `p` parameters, returning a “frozen” multinomial random variable:
The probability mass function for `multinomial` is

\[ f(x) = \frac{n!}{x_1! \cdots x_k!} p_1^{x_1} \cdots p_k^{x_k}, \]

supported on \( x = (x_1, \ldots, x_k) \) where each \( x_i \) is a nonnegative integer and their sum is \( n \).

New in version 0.19.0.

**Examples**

```python
>>> from scipy.stats import multinomial
>>> rv = multinomial(8, [.3, .2, .5])
>>> rv.pmf([1, 3, 4])
0.04200000000000072
```

The multinomial distribution for \( k = 2 \) is identical to the corresponding binomial distribution (tiny numerical differences notwithstanding):

```python
>>> from scipy.stats import binom
>>> multinomial.pmf([3, 4], n=7, p=[.4, .6])
0.29030399999999973
>>> binom.pmf(3, 7, 0.4)
0.29030400000000012
```

The functions `pmf`, `logpmf`, `entropy`, and `cov` support broadcasting, under the convention that the vector parameters (\( x \) and \( p \)) are interpreted as if each row along the last axis is a single object. For instance:

```python
>>> multinomial.pmf([(3, 4), (3, 5)], n=[7, 8], p=[.3, .7])
array([0.2268945, 0.25412184])
```

Here, \( x.shape == (2, 2) \), \( n.shape == (2,) \), and \( p.shape == (2,) \), but following the rules mentioned above they behave as if the rows \([3, 4]\) and \([3, 5]\) in \( x \) and \([.3, .7]\) in \( p \) were a single object, and as if we had \( x.shape == (2,) \), \( n.shape == (2,) \), and \( p.shape == () \). To obtain the individual elements without broadcasting, we would do this:

```python
>>> multinomial.pmf([3, 4], n=7, p=[.3, .7])
0.2268945
>>> multinomial.pmf([3, 5], 8, p=[.3, .7])
0.25412184
```

This broadcasting also works for `cov`, where the output objects are square matrices of size \( p.shape[-1] \).

For example:

```python
>>> multinomial.cov([4, 5], [[.3, .7], [.4, .6]])
array([[ 0.84, -0.84],
       [-0.84,  0.84]],
       [[ 1.2 , -1.2 ],
       [-1.2 ,  1.2 ]])
```

In this example, \( n.shape == (2,) \) and \( p.shape == (2, 2) \), and following the rules above, these broadcast as if \( p.shape == (2,) \). Thus the result should also be of shape \( (2,) \), but since each output is a \( 2 \times 2 \) matrix, the result in fact has shape \( (2, 2, 2) \), where \( result[0] \) is equal to `multinomial.cov(n=4, p=[.3, .7])` and \( result[1] \) is equal to `multinomial.cov(n=5, p=[.4, .6])`.

scipy.stats.special_ortho_group = <scipy.stats._multivariate.special_ortho_group_gen object>
A matrix-valued SO(N) random variable.

Return a random rotation matrix, drawn from the Haar distribution (the only uniform distribution on SO(n)).

The `dim` keyword specifies the dimension N.

**Parameters**

- `dim` : scalar
  Dimension of matrices

**Notes**

This class is wrapping the random_rot code from the MDP Toolkit, https://github.com/mdp-toolkit/mdp-toolkit

Return a random rotation matrix, drawn from the Haar distribution (the only uniform distribution on SO(n)).
For more information see http://en.wikipedia.org/wiki/Orthogonal_matrix#Randomization

See also the similar ortho_group.

**Examples**

```python
>>> from scipy.stats import special_ortho_group
>>> x = special_ortho_group.rvs(3)
```

```python
>>> np.dot(x, x.T)
array([[ 1.00000000e+00, 1.13231364e-17, -2.86852790e-16],
      [ 1.13231364e-17, 1.00000000e+00, -1.46845020e-16],
      [ -2.86852790e-16, -1.46845020e-16, 1.00000000e+00]])
```

```python
>>> import scipy.linalg
>>> scipy.linalg.det(x)
1.0
```

This generates one random matrix from SO(3). It is orthogonal and has a determinant of 1.

**Methods**

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rvs(dim=None, size=1, random_state=None)</td>
<td>Draw random samples from SO(N).</td>
</tr>
</tbody>
</table>

scipy.stats.ortho_group = <scipy.stats._multivariate.ortho_group_gen object>
A matrix-valued O(N) random variable.

Return a random orthogonal matrix, drawn from the O(N) Haar distribution (the only uniform distribution on O(N)).

The `dim` keyword specifies the dimension N.

**Parameters**

- `dim` : scalar
  Dimension of matrices
Notes
This class is closely related to `special_ortho_group`.
Some care is taken to avoid numerical error, as per the paper by Mezzadri.

References
[R678]

Examples

```python
>>> from scipy.stats import ortho_group
>>> x = ortho_group.rvs(3)

>>> np.dot(x, x.T)
array([[ 1.00000000e+00, 1.13231364e-17, -2.86852790e-16],
       [ 1.13231364e-17, 1.00000000e+00, -1.46845020e-16],
       [ -2.86852790e-16, -1.46845020e-16, 1.00000000e+00]])
```

```python
>>> import scipy.linalg

>>> np.fabs(scipy.linalg.det(x))
1.0
```

This generates one random matrix from O(3). It is orthogonal and has a determinant of +1 or -1.

Methods
---

`rvs(dim=None, size=1, random_state=None)`
Draw random samples from O(N).

scipy.stats.unitary_group = <scipy.stats.multivariate.unitary_group_gen object>
A matrix-valued U(N) random variable.

Return a random unitary matrix.

The `dim` keyword specifies the dimension N.

Parameters
---

`dim` : scalar
Dimension of matrices

Notes
This class is similar to `ortho_group`.

References
[R708]

Examples

```python
>>> from scipy.stats import unitary_group
>>> x = unitary_group.rvs(3)

>>> np.dot(x, x.conj().T)
array([[ 1.00000000e+00, 1.13231364e-17, -2.86852790e-16],
       [ 1.13231364e-17, 1.00000000e+00, -1.46845020e-16],
       [ -2.86852790e-16, -1.46845020e-16, 1.00000000e+00]])
```

This generates one random matrix from U(3). The dot product confirms that it is unitary up to machine precision.
Methods

scipy.stats.random_correlation = <scipy.stats._multivariate.random_correlation_gen object>
A random correlation matrix.

Return a random correlation matrix, given a vector of eigenvalues.

The eigs keyword specifies the eigenvalues of the correlation matrix, and implies the dimension.

Parameters
eigs : 1d ndarray
   Eigenvalues of correlation matrix.

Notes
Generates a random correlation matrix following a numerically stable algorithm spelled out by Davies & Higham. This algorithm uses a single O(N) similarity transformation to construct a symmetric positive semi-definite matrix, and applies a series of Givens rotations to scale it to have ones on the diagonal.

References
[R689]

Examples

```python
>>> from scipy.stats import random_correlation
>>> np.random.seed(514)
>>> x = random_correlation.rvs((.5, .8, 1.2, 1.5))
>>> x
array([[ 1. , -0.20387311, 0.18366501, -0.04953711],
       [-0.20387311, 1. , -0.24351129, 0.06703474],
       [ 0.18366501, -0.24351129, 1. , 0.38530195],
       [-0.04953711, 0.06703474, 0.38530195, 1. ]])
```

```python
>>> import scipy.linalg
>>> e, v = scipy.linalg.eigh(x)
>>> e
array([ 0.5, 0.8, 1.2, 1.5])
```

Methods

r vs(eigs=None, random_state=None) Draw random correlation matrices, all with eigenvalues eigs.

```
scipy.stats.bernoulli = <scipy.stats._discrete_distns.bernoulli_gen object>
```

A Bernoulli discrete random variable.

As an instance of the `rv_discrete` class, `bernoulli` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability mass function for `bernoulli` is:

\[
\text{bernoulli.pmf}(k) = \begin{cases} 
  1-p & \text{if } k = 0 \\
  p & \text{if } k = 1 
\end{cases}
\]

for \(k\) in \{0, 1\}.

`bernoulli` takes \(p\) as shape parameter.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `bernoulli.pmf(k, p, loc)` is identically equivalent to `bernoulli.pmf(k - loc, p)`.

**Examples**

```python
>>> from scipy.stats import bernoulli
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> p = 0.3
>>> mean, var, skew, kurt = bernoulli.stats(p, moments='mvsk')
```

Display the probability mass function (pmf):

```python
>>> x = np.arange(bernoulli.ppf(0.01, p), bernoulli.ppf(0.99, p))
>>> ax.plot(x, bernoulli.pmf(x, p), 'bo', ms=8, label='bernoulli pmf')
>>> ax.vlines(x, 0, bernoulli.pmf(x, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```python
>>> rv = bernoulli(p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyles='-', lw=5, alpha=0.5)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```
Check accuracy of \texttt{cdf} and \texttt{ppf}:

\begin{verbatim}
>>> prob = bernoulli.cdf(x, p)
>>> np.allclose(x, bernoulli.ppf(prob, p))
True
\end{verbatim}

Generate random numbers:

\begin{verbatim}
>>> r = bernoulli.rvs(p, size=1000)
\end{verbatim}

\textbf{Methods}

- \texttt{rvs}(p, \texttt{loc}=0, \texttt{size}=1, \texttt{random_state}=None): Random variates.
- \texttt{pmf}(k, p, \texttt{loc}=0): Probability mass function.
- \texttt{logpmf}(k, p, \texttt{loc}=0): Log of the probability mass function.
- \texttt{cdf}(k, p, \texttt{loc}=0): Cumulative distribution function.
- \texttt{logcdf}(k, p, \texttt{loc}=0): Log of the cumulative distribution function.
- \texttt{sf}(k, p, \texttt{loc}=0): Survival function (also defined as $1 - \text{cdf}$, but \texttt{sf} is sometimes more accurate).
- \texttt{logsf}(k, p, \texttt{loc}=0): Log of the survival function.
- \texttt{ppf}(q, p, \texttt{loc}=0): Percent point function (inverse of \texttt{cdf} — percentiles).
- \texttt{isf}(q, p, \texttt{loc}=0): Inverse survival function (inverse of \texttt{sf}).
- \texttt{stats}(p, \texttt{loc}=0, \texttt{moments}='mv\prime'): Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
- \texttt{entropy}(p, \texttt{loc}=0): (Differential) entropy of the RV.
- \texttt{expect(func, args=(p,), loc=0, lb=None, ub=None, conditional=False)}: Expected value of a function (of one argument) with respect to the distribution.
- \texttt{median}(p, \texttt{loc}=0): Median of the distribution.
- \texttt{mean}(p, \texttt{loc}=0): Mean of the distribution.
- \texttt{var}(p, \texttt{loc}=0): Variance of the distribution.
- \texttt{std}(p, \texttt{loc}=0): Standard deviation of the distribution.
- \texttt{interval(alpha, p, \texttt{loc}=0)}: Endpoints of the range that contains alpha percent of the distribution.
scipy.stats.binom = <scipy.stats._discrete_distns.binom_gen object>

A binomial discrete random variable.

As an instance of the rv_discrete class, binom object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability mass function for binom is:

\[
\text{binom.pmf}(k) = \binom{n}{k} \times p^k \times (1-p)^{(n-k)}
\]

for \( k \in \{0, 1, \ldots, n\} \).

binom takes \( n \) and \( p \) as shape parameters.

The probability mass function above is defined in the “standardized” form. To shift distribution use the loc parameter. Specifically, \( \text{binom.pmf}(k, n, p, \text{loc}) \) is identically equivalent to \( \text{binom.pmf}(k - \text{loc}, n, p) \).

Examples

```python
>>> from scipy.stats import binom
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> n, p = 5, 0.4
>>> mean, var, skew, kurt = binom.stats(n, p, moments='mvsk')
```

Display the probability mass function (pmf):

```python
>>> x = np.arange(binom.ppf(0.01, n, p),
...               binom.ppf(0.99, n, p))
>>> ax.plot(x, binom.pmf(x, n, p), 'bo', ms=8, label='binom pmf')
>>> ax.vlines(x, 0, binom.pmf(x, n, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```python
>>> rv = binom(n, p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyles='-', lw=1,
...           label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```
Check accuracy of cdf and ppf:

```python
>>> prob = binom.cdf(x, n, p)
>>> np.allclose(x, binom.ppf(prob, n, p))
True
```

Generate random numbers:

```python
>>> r = binom.rvs(n, p, size=1000)
```

**Methods**

- `rvs(n, p, loc=0, size=1, random_state=None)`: Random variates.
- `pmf(k, n, p, loc=0)`: Probability mass function.
- `logpmf(k, n, p, loc=0)`: Log of the probability mass function.
- `cdf(k, n, p, loc=0)`: Cumulative distribution function.
- `logcdf(k, n, p, loc=0)`: Log of the cumulative distribution function.
- `sf(k, n, p, loc=0)`: Survival function (also defined as 1 - cdf, but sf is sometimes more accurate).
- `logsf(k, n, p, loc=0)`: Log of the survival function.
- `ppf(q, n, p, loc=0)`: Percent point function (inverse of cdf — percentiles).
- `isf(q, n, p, loc=0)`: Inverse survival function (inverse of sf).
- `stats(n, p, loc=0, moments='mv')`: Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
- `entropy(n, p, loc=0)`: (Differential) entropy of the RV.
- `expect(func, args=(n, p), loc=0, lb=None, ub=None, conditional=False)`: Expected value of a function (of one argument) with respect to the distribution.
- `median(n, p, loc=0)`: Median of the distribution.
- `mean(n, p, loc=0)`: Mean of the distribution.
- `var(n, p, loc=0)`: Variance of the distribution.
- `std(n, p, loc=0)`: Standard deviation of the distribution.
- `interval(alpha, n, p, loc=0)`: Endpoints of the range that contains alpha percent of the distribution.
scipy.stats.boltzmann = <scipy.stats._discrete_distns.boltzmann_gen object>
A Boltzmann (Truncated Discrete Exponential) random variable.

As an instance of the rv_discrete class, boltzmann object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability mass function for boltzmann is:

\[ \text{boltzmann.pmf}(k) = \frac{(1 - \exp(-\lambda_0) \cdot \exp(-\lambda_0 \cdot k))}{1 - \exp(-\lambda_0 \cdot N)} \]

for \( k = 0, \ldots, N-1 \).

boltzmann takes \( \lambda_0 \) and \( N \) as shape parameters.

The probability mass function above is defined in the “standardized” form. To shift distribution use the loc parameter. Specifically, boltzmann.pmf(k, \( \lambda_0 \), N, loc) is identically equivalent to boltzmann.pmf(k - loc, \( \lambda_0 \), N).

Examples

```python
>>> from scipy.stats import boltzmann
>>> import matplotlib.pyplot as plt

>>> lambda_, N = 1.4, 19
>>> mean, var, skew, kurt = boltzmann.stats(lambda_, N, moments='mvsk')

>>> x = np.arange(boltzmann.ppf(0.01, lambda_, N),
...                boltzmann.ppf(0.99, lambda_, N))
>>> ax.plot(x, boltzmann.pmf(x, lambda_, N), 'bo', ms=8, label='boltzmann pmf')
>>> ax.vlines(x, 0, boltzmann.pmf(x, lambda_, N), colors='b', lw=5, alpha=0.5)

>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

5.27. Statistical functions (scipy.stats)
Check accuracy of cdf and ppf:

```python
>>> prob = boltzmann.cdf(x, lambda_, N)
>>> np.allclose(x, boltzmann.ppf(prob, lambda_, N))
True
```

Generate random numbers:

```python
>>> r = boltzmann.rvs(lambda_, N, size=1000)
```

scipy.stats.dlaplace = <scipy.stats._discrete_distns.dlaplace_gen object>
A Laplacian discrete random variable.

As an instance of the rv_discrete class, dlaplace object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability mass function for dlaplace is:

\[ dlaplace.pmf(k) = \tanh(a/2) \times \exp(-a\times\text{abs}(k)) \]

for \( a > 0 \).

dlaplace takes \( a \) as shape parameter.

The probability mass function above is defined in the “standardized” form. To shift distribution use the loc parameter. Specifically, dlaplace.pmf(k, a, loc) is identically equivalent to dlaplace.pmf(k - loc, a).

Examples

```python
>>> from scipy.stats import dlaplace
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> a = 0.8
>>> mean, var, skew, kurt = dlaplace.stats(a, moments='mvsk')
```

Display the probability mass function (pmf):

```python
>>> x = np.arange(dlaplace.ppf(0.01, a),
...               dlaplace.ppf(0.99, a))
>>> ax.plot(x, dlaplace.pmf(x, a), 'bo', ms=8, label='dlaplace pmf')
>>> ax.vlines(x, 0, dlaplace.pmf(x, a), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```python
>>> rv = dlaplace(a)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyles='-', lw=1,
...           label='frozen pmf')

scipy.stats.geom = <scipy.stats._discrete_distns.geom_gen object>
A geometric discrete random variable.

As an instance of the rv_discrete class, geom object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability mass function for geom is:

\[ \text{geom.pmf}(k) = (1-p)^{(k-1)} * p \]

for \( k \geq 1 \).

geom takes \( p \) as shape parameter.

The probability mass function above is defined in the “standardized” form. To shift distribution use the loc parameter. Specifically, geom.pmf(\( k, p, \text{loc} \)) is identically equivalent to geom.pmf(\( k - \text{loc}, p \)).

Examples

```python
>>> from scipy.stats import geom
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> p = 0.5
>>> mean, var, skew, kurt = geom.stats(p, moments='mvsk')
```

Display the probability mass function (pmf):

```python
>>> x = np.arange(geom.ppf(0.01, p), ...
... geom.ppf(0.99, p))
>>> ax.plot(x, geom.pmf(x, p), 'bo', ms=8, label='geom pmf')
>>> ax.vlines(x, 0, geom.pmf(x, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```python
>>> rv = geom(p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyles='-', lw=1,
... label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```
Check accuracy of cdf and ppf:

```python
>>> prob = geom.cdf(x, p)
>>> np.allclose(x, geom.ppf(prob, p))
True
```

Generate random numbers:

```python
>>> r = geom.rvs(p, size=1000)
```

**Methods**

- `rvs(p, loc=0, size=1, random_state=None)`: Random variates.
- `pmf(k, p, loc=0)`: Probability mass function.
- `logpmf(k, p, loc=0)`: Log of the probability mass function.
- `cdf(k, p, loc=0)`: Cumulative distribution function.
- `logcdf(k, p, loc=0)`: Log of the cumulative distribution function.
- `sf(k, p, loc=0)`: Survival function (also defined as `1 - cdf`, but `sf` is sometimes more accurate).
- `logsf(k, p, loc=0)`: Log of the survival function.
- `ppf(q, p, loc=0)`: Percent point function (inverse of `cdf` — percentiles).
- `isf(q, p, loc=0)`: Inverse survival function (inverse of `sf`).
- `stats(p, loc=0, moments='mv')`: Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
- `entropy(p, loc=0)`: (Differential) entropy of the RV.
- `expect(func, args=(p,), loc=0, lb=None, ub=None, conditional=False)`: Expected value of a function (of one argument) with respect to the distribution.
- `median(p, loc=0)`: Median of the distribution.
- `mean(p, loc=0)`: Mean of the distribution.
- `var(p, loc=0)`: Variance of the distribution.
- `std(p, loc=0)`: Standard deviation of the distribution.
- `interval(alpha, p, loc=0)`: Endpoints of the range that contains alpha percent of the distribution.
A hypergeometric discrete random variable.

The hypergeometric distribution models drawing objects from a bin. \( M \) is the total number of objects, \( n \) is total number of Type I objects. The random variate represents the number of Type I objects in \( N \) drawn without replacement from the total population.

As an instance of the \texttt{rv_discrete} class, \texttt{hypergeom} object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The symbols used to denote the shape parameters (\( M, n, \) and \( N \)) are not universally accepted. See the Examples for a clarification of the definitions used here.

The probability mass function is defined as,

\[
p(k, M, n, N) = \frac{\binom{n}{k} \binom{M-n}{N-k}}{\binom{M}{N}}
\]

for \( k \in [\max(0, N - M + n), \min(n, N)] \), where the binomial coefficients are defined as,

\[
\binom{n}{k} = \frac{n!}{k!(n-k)!}.
\]

The probability mass function above is defined in the “standardized” form. To shift distribution use the \texttt{loc} parameter. Specifically, \texttt{hypergeom.pmf(k, M, n, N, loc)} is identically equivalent to \texttt{hypergeom.pmf(k - loc, M, n, N)}.

**Examples**

```python
>>> from scipy.stats import hypergeom
>>> import matplotlib.pyplot as plt

Suppose we have a collection of 20 animals, of which 7 are dogs. Then if we want to know the probability of finding a given number of dogs if we choose at random 12 of the 20 animals, we can initialize a frozen distribution and plot the probability mass function:

```
Instead of using a frozen distribution we can also use `hypergeom` methods directly. To for example obtain the cumulative distribution function, use:

```python
>>> prb = hypergeom.cdf(x, M, n, N)
```

And to generate random numbers:

```python
>>> R = hypergeom.rvs(M, n, N, size=10)
```

`scipy.stats.logser = <scipy.stats._discrete_distns.logser_gen object>`
A Logarithmic (Log-Series, Series) discrete random variable.

As an instance of the `rv_discrete` class, `logser` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability mass function for `logser` is:

\[
\text{logser.pmf}(k) = - \frac{p^k}{k \log(1-p)}
\]

for \( k \geq 1 \).

`logser` takes `p` as shape parameter.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `logser.pmf(k, p, loc)` is identically equivalent to `logser.pmf(k - loc, p)`.

**Examples**

```python
>>> from scipy.stats import logser
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> p = 0.6
>>> mean, var, skew, kurt = logser.stats(p, moments='mvsk')
```

Display the probability mass function (pmf):

```python
>>> x = np.arange(logser.ppf(0.01, p), logser.ppf(0.99, p))
>>> ax.plot(x, logser.pmf(x, p), 'bo', ms=8, label='logser pmf')
>>> ax.vlines(x, 0, logser.pmf(x, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```python
>>> rv = logser(p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyles='-', lw=1, ... label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```
Check accuracy of \texttt{cdf} and \texttt{ppf}:

```python
>>> prob = logser.cdf(x, p)
>>> np.allclose(x, logser.ppf(prob, p))
```

True

Generate random numbers:

```python
>>> r = logser.rvs(p, size=1000)
```

scipy.stats.nbinom = <scipy.stats._discrete_distns.nbinom_gen object>
A negative binomial discrete random variable.

As an instance of the `rv_discrete` class, nbinom object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

Negative binomial distribution describes a sequence of i.i.d. Bernoulli trials, repeated until a predefined, non-random number of successes occurs.

The probability mass function of the number of failures for `nbinom` is:

```python
nbinom.pmf(k) = choose(k+n-1, n-1) * p**n * (1-p)**k
```

for `k >= 0`.

`nbinom` takes `n` and `p` as shape parameters where `n` is the number of successes, whereas `p` is the probability of a single success.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `nbinom.pmf(k, n, p, loc)` is identically equivalent to `nbinom.pmf(k - loc, n, p)`.

**Examples**

```python
>>> from scipy.stats import nbinom
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> n, p = 0.4, 0.4
>>> mean, var, skew, kurt = nbinom.stats(n, p, moments='mvsk')
```

Display the probability mass function (pmf):

```python
>>> x = np.arange(nbinom.ppf(0.01, n, p), ...
    ...                nbinom.ppf(0.99, n, p))
>>> ax.plot(x, nbinom.pmf(x, n, p), 'bo', ms=8, label='nbinom pmf')
>>> ax.vlines(x, 0, nbinom.pmf(x, n, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```python
>>> rv = nbinom(n, p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyles='-', lw=1, ...
    ...         label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
```

```python
>>> plt.show()
```
Check accuracy of cdf and ppf:

```python
>>> prob = nbinom.cdf(x, n, p)
>>> np.allclose(x, nbinom.ppf(prob, n, p))
```

```python
True
```

Generate random numbers:

```python
>>> r = nbinom.rvs(n, p, size=1000)
```

scipy.stats.planck = <scipy.stats._discrete_distns.planck_gen object>
A Planck discrete exponential random variable.

As an instance of the rv_discrete class, planck object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes
The probability mass function for planck is:

\[ \text{planck.pmf}(k) = (1-\exp(-\lambda_\ast))\ast\exp(-\lambda_\ast k) \]

for \( k \ast \lambda_\ast \geq 0. \)

planck takes \( \lambda_\ast \) as shape parameter.

The probability mass function above is defined in the “standardized” form. To shift distribution use the loc parameter. Specifically, planck.pmf(k, lambda_, loc) is identically equivalent to planck.pmf(k - loc, lambda_).

Examples

```python
>>> from scipy.stats import planck
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> lambda_ = 0.51
>>> mean, var, skew, kurt = planck.stats(lambda_, moments='mvsk')
```

Display the probability mass function (pmf):

```python
>>> x = np.arange(planck.ppf(0.01, lambda_),
...                planck.ppf(0.99, lambda_))
>>> ax.plot(x, planck.pmf(x, lambda_), 'bo', ms=8, label='planck pmf')
>>> ax.vlines(x, 0, planck.pmf(x, lambda_), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```python
>>> rv = planck(lambda_)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyles='-', lw=1, label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```
Check accuracy of cdf and ppf:

```python
>>> prob = planck.cdf(x, lambda_)
>>> np.allclose(x, planck.ppf(prob, lambda_))
True
```

Generate random numbers:

```python
>>> r = planck.rvs(lambda_, size=1000)
```

scipy.stats.poisson = <scipy.stats._discrete_distns.poisson_gen object>
A Poisson discrete random variable.

As an instance of the rv_discrete class, poisson object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes
The probability mass function for poisson is:

\[
\text{poisson.pmf}(k) = \exp(-\mu) \times \mu^k / k!
\]

for \( k \geq 0 \).

poisson takes \( \mu \) as shape parameter.

The probability mass function above is defined in the “standardized” form. To shift distribution use the loc parameter. Specifically, poisson.pmf(k, \( \mu \), loc) is identically equivalent to poisson.pmf(k - loc, \( \mu \)).

Examples

```python
>>> from scipy.stats import poisson
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> mu = 0.6
>>> mean, var, skew, kurt = poisson.stats(mu, moments='mvsk')
```

Display the probability mass function (pmf):

```python
>>> x = np.arange(poisson.ppf(0.01, mu),
...                poisson.ppf(0.99, mu))
>>> ax.plot(x, poisson.pmf(x, mu), 'bo', ms=8, label='poisson pmf')
>>> ax.vlines(x, 0, poisson.pmf(x, mu), colors='b', lw=5, alpha=0.5)

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```python
>>> rv = poisson(mu)
>>> ax.vlines(x, rv.pmf(x), colors='k', linestyles='-', lw=1,
...           label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```
Check accuracy of `cdf` and `ppf`:

```python
>>> prob = poisson.cdf(x, mu)
>>> np.allclose(x, poisson.ppf(prob, mu))
True
```

Generate random numbers:

```python
>>> r = poisson.rvs(mu, size=1000)
```

scipy.stats.randint = <scipy.stats._discrete_distns.randint_gen object>

A uniform discrete random variable.

As an instance of the `rv_discrete` class, `randint` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability mass function for `randint` is:

\[
\text{randint.pmf}(k) = \frac{1}{(\text{high} - \text{low})}
\]

for \( k = \text{low}, \ldots, \text{high} - 1 \).

`randint` takes `low` and `high` as shape parameters.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `randint.pmf(k, low, high, loc)` is identically equivalent to `randint.pmf(k - loc, low, high)`.

**Examples**

```python
>>> from scipy.stats import randint
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
def randint.stats(low, high, moments='mvsk')
```

Display the probability mass function (pmf):

```python
>>> x = np.arange(randint.ppf(0.01, low, high),
... randint.ppf(0.99, low, high))
>>> ax.plot(x, randint.pmf(x, low, high), 'bo', ms=8, label='randint pmf')
>>> ax.vlines(x, 0, randint.pmf(x, low, high), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```python
>>> rv = randint(low, high)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyles='-', lw=1,
... label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```
Check accuracy of cdf and ppf:

```python

scipy.stats.skellam = <scipy.stats._discrete_distns.skellam_gen object>

A Skellam discrete random variable.

As an instance of the `rv_discrete` class, `skellam` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

Probability distribution of the difference of two correlated or uncorrelated Poisson random variables.

Let \( k_1 \) and \( k_2 \) be two Poisson-distributed r.v. with expected values \( \lambda_1 \) and \( \lambda_2 \). Then, \( k_1 - k_2 \) follows a Skellam distribution with parameters 
\[
\mu_1 = \lambda_1 - \rho \sqrt{\lambda_1 \lambda_2}
\]
and
\[
\mu_2 = \lambda_2 - \rho \sqrt{\lambda_1 \lambda_2},
\]
where \( \rho \) is the correlation coefficient between \( k_1 \) and \( k_2 \). If the two Poisson-distributed r.v. are independent then \( \rho = 0 \).

Parameters \( \mu_1 \) and \( \mu_2 \) must be strictly positive.

For details see: http://en.wikipedia.org/wiki/Skellam_distribution

`skellam` takes \( \mu_1 \) and \( \mu_2 \) as shape parameters.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `skellam.pmf(k, \mu_1, \mu_2, \text{loc})` is identically equivalent to `skellam.pmf(k - \text{loc}, \mu_1, \mu_2)`.

**Examples**

```python
>>> from scipy.stats import skellam
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
Calculate a few first moments:

```python
>>> mu1, mu2 = 15, 8
>>> mean, var, skew, kurt = skellam.stats(mu1, mu2, moments='mvsk')
```

Display the probability mass function (pmf):

```python
>>> x = np.arange(skellam.ppf(0.01, mu1, mu2), skellam.ppf(0.99, mu1, mu2))
>>> ax.plot(x, skellam.pmf(x, mu1, mu2), 'bo', ms=8, label='skellam pmf')
>>> ax.vlines(x, 0, skellam.pmf(x, mu1, mu2), colors='b', lw=5, alpha=0.5)
```Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```python
>>> rv = skellam(mu1, mu2)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyles='-', lw=1,
...           label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```
Check accuracy of \texttt{cdf} and \texttt{ppf}:

```python
>>> prob = skellam.cdf(x, mu1, mu2)
>>> np.allclose(x, skellam.ppf(prob, mu1, mu2))
True
```

Generate random numbers:

```python
>>> r = skellam.rvs(mu1, mu2, size=1000)
```

scipy.stats.zipf = <scipy.stats._discrete_distns.zipf_gen object>
A Zipf discrete random variable.

As an instance of the rv_discrete class, zipf object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**Notes**

The probability mass function for zipf is:

\[ \text{zipf.pmf}(k, a) = \frac{1}{\zeta(a) \times k^a} \]

for \( k >= 1 \).

zipf takes \( a \) as shape parameter.

The probability mass function above is defined in the “standardized” form. To shift distribution use the loc parameter. Specifically, zipf.pmf(\( k, a, loc \)) is identically equivalent to zipf.pmf(\( k - loc, a \)).

**Examples**

```python
>>> from scipy.stats import zipf
>>> import matplotlib.pyplot as plt

>>> fig, ax = plt.subplots(1, 1)

Calculate a few first moments:

```python
>>> a = 6.5
>>> mean, var, skew, kurt = zipf.stats(a, moments='mvsk')
```

Display the probability mass function (pmf):

```python
>>> x = np.arange(zipf.ppf(0.01, a),
>>> ... zipf.ppf(0.99, a))
>>> ax.plot(x, zipf.pmf(x, a), 'bo', ms=8, label='zipf pmf')
>>> ax.vlines(x, 0, zipf.pmf(x, a), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```python
>>> rv = zipf(a)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyles='-', lw=1,
>>> ... label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)

</tbody>
</table>

scipy.stats.describe (a, axis=0, ddof=1, bias=True, nan_policy='propagate')

Compute several descriptive statistics of the passed array.

Parameters

- **a**: array_like
  Input data.
- **axis**: int or None, optional
  Axis along which statistics are calculated. Default is 0. If None, compute over the whole array a.
- **ddof**: int, optional
  Delta degrees of freedom (only for variance). Default is 1.
- **bias**: bool, optional
  If False, then the skewness and kurtosis calculations are corrected for statistical bias.
- **nan_policy**: ['propagate', 'raise', 'omit'], optional
  Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default is ‘propagate’.

Returns

- **nobs**: int or ndarrray of ints
  Number of observations (length of data along axis). When ‘omit’ is chosen as nan_policy, each column is counted separately.
- **minmax**: tuple of ndarrays or floats
  Minimum and maximum value of data array.
**mean**: ndarray or float
Arithmetic mean of data along axis.

**variance**: ndarray or float
Unbiased variance of the data along axis, denominator is number of observations minus one.

**skewness**: ndarray or float
Skewness, based on moment calculations with denominator equal to the number of observations, i.e. no degrees of freedom correction.

**kurtosis**: ndarray or float
Kurtosis (Fisher). The kurtosis is normalized so that it is zero for the normal distribution. No degrees of freedom are used.

**See also:**

*skew*, *kurtosis*

**Examples**

```python
>>> from scipy import stats
>>> a = np.arange(10)
>>> stats.describe(a)
DescribeResult(nobs=10, minmax=(0, 9), mean=4.5, variance=9.1666666666666661,
    skewness=0.0, kurtosis=-1.2242424242424244)
>>> b = [[1, 2], [3, 4]]
>>> stats.describe(b)
DescribeResult(nobs=2, minmax=(array([1, 2]), array([3, 4])),
    mean=array([ 2., 3.]), variance=array([ 2., 2.]),
    skewness=array([ 0., 0.]), kurtosis=array([-2., -2.]))
```

**scipy.stats.gmean**(a, axis=0, dtype=None)

Compute the geometric mean along the specified axis.

Return the geometric average of the array elements. That is: n-th root of (x1 * x2 * ... * xn)

**Parameters**

- **a**: array_like
  Input array or object that can be converted to an array.

- **axis**: int or None, optional
  Axis along which the geometric mean is computed. Default is 0. If None, compute over the whole array `a`.

- **dtype**: dtype, optional
  Type of the returned array and of the accumulator in which the elements are summed. If dtype is not specified, it defaults to the dtype of `a`, unless `a` has an integer dtype with a precision less than that of the default platform integer. In that case, the default platform integer is used.

**Returns**

- **gmean**: ndarray
  see dtype parameter above

**See also:**

*numpy.mean* Arithmetic average

*numpy.average*

  Weighted average

*hmean* Harmonic mean

**Notes**

The geometric average is computed over a single dimension of the input array, axis=0 by default, or all values in the array if axis=None. float64 intermediate and return values are used for integer inputs.
Use masked arrays to ignore any non-finite values in the input or that arise in the calculations such as Not a Number and infinity because masked arrays automatically mask any non-finite values.

**Examples**

```python
>>> from scipy.stats import gmean
>>> gmean([1, 4])
2.0
>>> gmean([1, 2, 3, 4, 5, 6, 7])
3.3800151591412964
```

```python
scipy.stats.hmean(a, axis=0, dtype=None)
```

Calculate the harmonic mean along the specified axis.

That is: \( n / (1/x_1 + 1/x_2 + \ldots + 1/x_n) \)

**Parameters**

- `a`: array_like
  - Input array, masked array or object that can be converted to an array.
- `axis`: int or None, optional
  - Axis along which the harmonic mean is computed. Default is 0. If None, compute over the whole array `a`.
- `dtype`: dtype, optional
  - Type of the returned array and of the accumulator in which the elements are summed. If `dtype` is not specified, it defaults to the dtype of `a`, unless `a` has an integer `dtype` with a precision less than that of the default platform integer. In that case, the default platform integer is used.

**Returns**

- `hmean`: ndarray
  - see `dtype` parameter above

**See also:**

- `numpy.mean` Arithmetic average
- `numpy.average` Weighted average
- `gmean` Geometric mean

**Notes**

The harmonic mean is computed over a single dimension of the input array, axis=0 by default, or all values in the array if axis=None. float64 intermediate and return values are used for integer inputs.

Use masked arrays to ignore any non-finite values in the input or that arise in the calculations such as Not a Number and infinity.

**Examples**

```python
>>> from scipy.stats import hmean
>>> hmean([1, 4])
1.6000000000000001
>>> hmean([1, 2, 3, 4, 5, 6, 7])
2.6997245179063363
```

```python
scipy.stats.kurtosis(a, axis=0, fisher=True, bias=True, nan_policy='propagate')
```

Compute the kurtosis (Fisher or Pearson) of a dataset.

Kurtosis is the fourth central moment divided by the square of the variance. If Fisher’s definition is used, then 3.0 is subtracted from the result to give 0.0 for a normal distribution.

If bias is False then the kurtosis is calculated using k statistics to eliminate bias coming from biased moment estimators.
Use `kurtosistest` to see if result is close enough to normal.

**Parameters**
- `a` : array
data for which the kurtosis is calculated
- `axis` : int or None, optional
  Axis along which the kurtosis is calculated. Default is 0. If None, compute over the whole array `a`.
- `fisher` : bool, optional
  If True, Fisher’s definition is used (normal ==> 0.0). If False, Pearson’s definition is used (normal ==> 3.0).
- `bias` : bool, optional
  If False, then the calculations are corrected for statistical bias.
- `nan_policy` : {'propagate', 'raise', 'omit'}, optional
  Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default is ‘propagate’.

**Returns**
- `kurtosis` : array
  The kurtosis of values along an axis. If all values are equal, return -3 for Fisher’s definition and 0 for Pearson’s definition.

**References**
[R660]

**Examples**
```python
>>> from scipy.stats import kurtosis

>>> kurtosis([1, 2, 3, 4, 5])
-1.3
```

scipy.stats.kurtosistest `a`, `axis=0`, `nan_policy='propagate'`
Test whether a dataset has normal kurtosis.

This function tests the null hypothesis that the kurtosis of the population from which the sample was drawn is that of the normal distribution: \( \text{kurtosis} = \frac{3(n-1)}{n+1} \).

**Parameters**
- `a` : array
  array of the sample data
- `axis` : int or None, optional
  Axis along which to compute test. Default is 0. If None, compute over the whole array `a`.
- `nan_policy` : {'propagate', 'raise', 'omit'}, optional
  Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default is ‘propagate’.

**Returns**
- `statistic` : float
  The computed z-score for this test.
- `pvalue` : float
  The 2-sided p-value for the hypothesis test

**Notes**
Valid only for n>20. The Z-score is set to 0 for bad entries. This function uses the method described in [R661].

**References**
[R661]
Examples

```python
>>> from scipy.stats import kurtosistest
>>> kurtosistest(list(range(20))
KurtosistestResult(statistic=-1.7058104152122062, pvalue=0.088043383325283484)

>>> np.random.seed(28041990)
>>> s = np.random.normal(0, 1, 1000)
>>> kurtosistest(s)
KurtosistestResult(statistic=1.2317590987707365, pvalue=0.21803908613450895)
```

`scipy.stats.mode(a, axis=0, nan_policy='propagate')`

Return an array of the modal (most common) value in the passed array.

If there is more than one such value, only the smallest is returned. The bin-count for the modal bins is also returned.

**Parameters**

- `a` : array_like
  n-dimensional array of which to find mode(s).
- `axis` : int or None, optional
  Axis along which to operate. Default is 0. If None, compute over the whole array `a`.
- `nan_policy` : {'propagate', 'raise', 'omit'}, optional
  Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns**

- `mode` : ndarray
  Array of modal values.
- `count` : ndarray
  Array of counts for each mode.

**Examples**

```python
>>> a = np.array([[6, 8, 3, 0],
...                [3, 2, 1, 7],
...                [8, 1, 8, 4],
...                [5, 3, 0, 5],
...                [4, 7, 5, 9]])
>>> from scipy import stats
>>> stats.mode(a)
(array([[3, 1, 0, 0]]), array([[1, 1, 1, 1]]))
```

To get mode of whole array, specify `axis=None`:

```python
>>> stats.mode(a, axis=None)
(array([3]), array([3]))
```

`scipy.stats.moment(a, moment=1, axis=0, nan_policy='propagate')`

Calculate the nth moment about the mean for a sample.

A moment is a specific quantitative measure of the shape of a set of points. It is often used to calculate coefficients of skewness and kurtosis due to its close relationship with them.

**Parameters**

- `a` : array_like
  data
- `moment` : int or array_like of ints, optional
  order of central moment that is returned. Default is 1.
- `axis` : int or None, optional
Axis along which the central moment is computed. Default is 0. If None, compute over the whole array \( a \).

**nan_policy** : {'propagate', 'raise', 'omit'}, optional
Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default is ‘propagate’.

**Returns**

n-th central moment : ndarray or float
The appropriate moment along the given axis or over all values if axis is None. The denominator for the moment calculation is the number of observations, no degrees of freedom correction is done.

**See also:**

kurtosis, skew, describe

**Notes**
The k-th central moment of a data sample is:

\[
m_k = \frac{1}{n} \sum_{i=1}^{n} (x_i - \bar{x})^k
\]

Where \( n \) is the number of samples and \( \bar{x} \) is the mean. This function uses exponentiation by squares \([R670]\) for efficiency.

**References**

[R670]

**Examples**

```python
>>> from scipy.stats import moment
>>> moment([1, 2, 3, 4, 5], moment=1)
0.0
>>> moment([1, 2, 3, 4, 5], moment=2)
2.0
```

**scipy.stats.normaltest** \((a, axis=0, nan_policy='propagate')\)
Test whether a sample differs from a normal distribution.

This function tests the null hypothesis that a sample comes from a normal distribution. It is based on D’Agostino and Pearson’s \([R675], [R676]\) test that combines skew and kurtosis to produce an omnibus test of normality.

**Parameters**

- **a** : array_like
  The array containing the sample to be tested.

- **axis** : int or None, optional
  Axis along which to compute test. Default is 0. If None, compute over the whole array \( a \).

- **nan_policy** : {'propagate', 'raise', 'omit'}, optional
  Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default is ‘propagate’.

**Returns**

- **statistic** : float or array
  \( s^2 + k^2 \), where \( s \) is the z-score returned by skewtest and \( k \) is the z-score returned by kurtosistest.

- **pvalue** : float or array
  A 2-sided chi squared probability for the hypothesis test.
References

[R675], [R676]

Examples

```python
>>> from scipy import stats
>>> pts = 1000
>>> a = np.random.normal(0, 1, size=pts)
>>> b = np.random.normal(2, 1, size=pts)
>>> x = np.concatenate((a, b))
>>> k2, p = stats.normaltest(x)
>>> alpha = 1e-3
>>> print("p = {:.g}\n".format(p))
p = 3.27207e-11
>>> if p < alpha:
...    # null hypothesis: x comes from a normal distribution
...    print("The null hypothesis can be rejected")
... else:
...    print("The null hypothesis cannot be rejected")
The null hypothesis can be rejected
```

```python
scipy.stats.skew(a, axis=0, bias=True, nan_policy='propagate')
```

Compute the skewness of a data set.

For normally distributed data, the skewness should be about 0. For unimodal continuous distributions, a skewness value $> 0$ means that there is more weight in the right tail of the distribution. The function `skewtest` can be used to determine if the skewness value is close enough to 0, statistically speaking.

**Parameters**

- `a` : ndarray
  data
- `axis` : int or None, optional
  Axis along which skewness is calculated. Default is 0. If None, compute over the whole array `a`.
- `bias` : bool, optional
  If False, then the calculations are corrected for statistical bias.
- `nan_policy` : {'propagate', 'raise', 'omit'}, optional
  Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default is ‘propagate’.

**Returns**

- `skewness` : ndarray
  The skewness of values along an axis, returning 0 where all values are equal.

References

[R696]

Examples

```python
>>> from scipy.stats import skew
>>> skew([1, 2, 3, 4, 5])
0.0
>>> skew([2, 8, 0, 4, 1, 9, 9, 0])
0.2650554122698573
```

```python
scipy.stats.skewtest(a, axis=0, nan_policy='propagate')
```

Test whether the skew is different from the normal distribution.

5.27. Statistical functions (`scipy.stats`) 1965
This function tests the null hypothesis that the skewness of the population that the sample was drawn from is the same as that of a corresponding normal distribution.

**Parameters**
- `a`: array
  The data to be tested
- `axis`: int or None, optional
  Axis along which statistics are calculated. Default is 0. If None, compute over the whole array `a`.
- `nan_policy`: {'propagate', 'raise', 'omit'}, optional
  Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default is ‘propagate’.

**Returns**
- `statistic`: float
  The computed z-score for this test.
- `pvalue`: float
  A 2-sided p-value for the hypothesis test

**Notes**
The sample size must be at least 8.

**References**
[R698]

**Examples**

```python
>>> from scipy.stats import skewtest
>>> skewtest([1, 2, 3, 4, 5, 6, 7, 8])
SkewtestResult(statistic=1.0108048609177787, pvalue=0.31210983614218968)
>>> skewtest([2, 8, 0, 4, 1, 9, 9, 0])
SkewtestResult(statistic=0.44626385374196975, pvalue=0.65540666312754592)
>>> skewtest([1, 2, 3, 4, 5, 6, 7, 8000])
SkewtestResult(statistic=3.5717735103604071, pvalue=0.00035457199058231331)
>>> skewtest([100, 100, 100, 100, 100, 100, 100, 101])
SkewtestResult(statistic=3.5717766638478072, pvalue=0.000354567720281634)
```

scipy.stats.kstat(data, n=2)

Return the nth k-statistic (1≤n≤4 so far).

The nth k-statistic $k_n$ is the unique symmetric unbiased estimator of the nth cumulant $\kappa_n$.

**Parameters**
- `data`: array_like
  Input array. Note that n-D input gets flattened.
- `n`: int, {1, 2, 3, 4}, optional
  Default is equal to 2.

**Returns**
- `kstat`: float
  The nth k-statistic.

See also:
- `kstatvar`
  Returns an unbiased estimator of the variance of the k-statistic.
- `moment`
  Returns the n-th central moment about the mean for a sample.

**Notes**
For a sample size $n$, the first few k-statistics are given by:

\[ k_1 = \mu k_2 = \frac{n}{n-1} m_2 k_3 = \frac{n^2}{(n-1)(n-2)} m_3 k_4 = \frac{n^2[(n+1)m_4 - 3(n-1)m_2^2]}{(n-1)(n-2)(n-3)} \]

where $\mu$ is the sample mean, $m_2$ is the sample variance, and $m_i$ is the i-th sample central moment.
References

http://mathworld.wolfram.com/k-Statistic.html
http://mathworld.wolfram.com/Cumulant.html

Examples

```python
>>> from scipy import stats
>>> rndm = np.random.RandomState(1234)

As sample size increases, n-th moment and n-th k-statistic converge to the same number (although they aren’t identical). In the case of the normal distribution, they converge to zero.

```python
>>> for n in [2, 3, 4, 5, 6, 7]:
...     x = rndm.normal(size=10**n)
...     m, k = stats.moment(x, 3), stats.kstat(x, 3)
...     print("%.3g %.3g %.3g % (m, k, m-k)
...     -0.631 -0.651 0.0194
0.0282 0.0283 -8.49e-05
-0.0454 -0.0454 1.36e-05
7.53e-05 7.53e-05 -2.26e-09
0.00166 0.00166 -4.99e-09
-2.88e-06 -2.88e-06 8.63e-13
```

scipy.stats.kstatvar(data, n=2)

Returns an unbiased estimator of the variance of the k-statistic.

See kstat for more details of the k-statistic.

**Parameters**

- data : array_like
  Input array. Note that n-D input gets flattened.

- n : int, {1, 2}, optional
  Default is equal to 2.

**Returns**

- kstatvar : float
  The nth k-statistic variance.

See also:

- kstat
- moment

**Notes**

The variances of the first few k-statistics are given by:

\[ \text{var}(k_1) = \frac{\kappa^2}{n} \]
\[ \text{var}(k_2) = \frac{\kappa^4}{n + 2\kappa^2/\kappa^4} \]
\[ \text{var}(k_3) = \frac{\kappa^6}{n + 9\kappa^2/\kappa^4 + 9\kappa^4/\kappa^6} \]
\[ \text{var}(k_4) = \frac{6n\kappa^3}{(n-1)(n-2)(n-3)} \frac{\kappa^8}{n + 16\kappa^2/\kappa^6 + 48\kappa^4/\kappa^8} \]

scipy.stats.tmean(a, limits=None, inclusive=(True, True), axis=None)

Compute the trimmed mean.

This function finds the arithmetic mean of given values, ignoring values outside the given limits.

**Parameters**

- a : array_like
  Array of values.

- limits : None or (lower limit, upper limit), optional
  Values in the input array less than the lower limit or greater than the upper limit will be ignored. When limits is None (default), then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval.
inclusive : (bool, bool), optional
A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).

axis : int or None, optional

Returns
tmean : float
Axis along which to compute test. Default is None.

See also:
trim_mean returns mean after trimming a proportion from both tails.

Examples

```python
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tmean(x)
9.5
>>> stats.tmean(x, (3,17))
10.0
```

scipy.stats.tvar(a, limits=None, inclusive=(True, True), axis=0, ddof=1)

Compute the trimmed variance.

This function computes the sample variance of an array of values, while ignoring values which are outside of given limits.

Parameters

a : array_like
Array of values.

limits : None or (lower limit, upper limit), optional
Values in the input array less than the lower limit or greater than the upper limit will be ignored. When limits is None, then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval. The default value is None.

inclusive : (bool, bool), optional
A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).

axis : int or None, optional
Axis along which to operate. Default is 0. If None, compute over the whole array a.

ddof : int, optional
Delta degrees of freedom. Default is 1.

Returns
tvar : float
Trimmed variance.

Notes
tvar computes the unbiased sample variance, i.e. it uses a correction factor n / (n - 1).

Examples

```python
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tvar(x)
35.0
>>> stats.tvar(x, (3,17))
20.0
```
scipy.stats.tmin(a, lowerlimit=None, axis=0, inclusive=True, nan_policy='propagate')

Compute the trimmed minimum.

This function finds the minimum value of an array $a$ along the specified axis, but only considering values greater than a specified lower limit.

**Parameters**
- $a$: array_like
  array of values
- lowerlimit : None or float, optional
  Values in the input array less than the given limit will be ignored. When lowerlimit is None, then all values are used. The default value is None.
- axis : int or None, optional
  Axis along which to operate. Default is 0. If None, compute over the whole array $a$.
- inclusive : {True, False}, optional
  This flag determines whether values exactly equal to the lower limit are included. The default value is True.
- nan_policy : {'propagate', 'raise', 'omit'}, optional
  Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default is ‘propagate’.

**Returns**
- tmin : float, int or ndarray

**Examples**

```python
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tmin(x)
0

>>> stats.tmin(x, 13)
13

>>> stats.tmin(x, 13, inclusive=False)
14
```

scipy.stats.tmax(a, upperlimit=None, axis=0, inclusive=True, nan_policy='propagate')

Compute the trimmed maximum.

This function computes the maximum value of an array along a given axis, while ignoring values larger than a specified upper limit.

**Parameters**
- $a$: array_like
  array of values
- upperlimit : None or float, optional
  Values in the input array greater than the given limit will be ignored. When upperlimit is None, then all values are used. The default value is None.
- axis : int or None, optional
  Axis along which to operate. Default is 0. If None, compute over the whole array $a$.
- inclusive : {True, False}, optional
  This flag determines whether values exactly equal to the upper limit are included. The default value is True.
- nan_policy : {'propagate', 'raise', 'omit'}, optional
  Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default is ‘propagate’.
Returns

tmax : float, int or ndarray

Examples

```python
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tmax(x)
19

>>> stats.tmax(x, 13)
13

>>> stats.tmax(x, 13, inclusive=False)
12

scipy.stats.tstd(a, limits=None, inclusive=(True, True), axis=0, ddof=1)
Compute the trimmed sample standard deviation.

This function finds the sample standard deviation of given values, ignoring values outside the given limits.

Parameters

a : array_like
array of values

limits : None or (lower limit, upper limit), optional
Values in the input array less than the lower limit or greater than the upper limit will be ignored. When limits is None, then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval. The default value is None.

inclusive : (bool, bool), optional
A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).

axis : int or None, optional
Axis along which to operate. Default is 0. If None, compute over the whole array a.

ddof : int, optional
Delta degrees of freedom. Default is 1.

Returns

tstd : float
Delta degrees of freedom. Default is 1.

Notes
tstd computes the unbiased sample standard deviation, i.e. it uses a correction factor \( \frac{n}{n - 1} \).

Examples

```python
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tstd(x)
5.9160797830996161

>>> stats.tstd(x, (3,17))
4.4721359549995796

scipy.stats.tsem(a, limits=None, inclusive=(True, True), axis=0, ddof=1)
Compute the trimmed standard error of the mean.

This function finds the standard error of the mean for given values, ignoring values outside the given limits.

Parameters

a : array_like
array of values
limits : None or (lower limit, upper limit), optional
Values in the input array less than the lower limit or greater than the upper limit will be ignored. When limits is None, then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval. The default value is None.

inclusive : (bool, bool), optional
A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).

axis : int or None, optional
Axis along which to operate. Default is 0. If None, compute over the whole array \(a\).

d dof : int, optional
Delta degrees of freedom. Default is 1.

Returns

tsem : float
Delta degrees of freedom. Default is 1.

Notes
tsem uses unbiased sample standard deviation, i.e. it uses a correction factor \(n / (n - 1)\).

Examples

```python
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tsem(x)
1.3228756555322954
>>> stats.tsem(x, (3,17))
1.1547005383792515
```

scipy.stats.variation (a, axis=0, nan_policy='propagate')
Compute the coefficient of variation, the ratio of the biased standard deviation to the mean.

Parameters

\(a\) : array_like
Input array.

axis : int or None, optional
Axis along which to calculate the coefficient of variation. Default is 0. If None, compute over the whole array \(a\).

nan_policy : {'propagate', 'raise', 'omit'}, optional
Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default is ‘propagate’.

Returns

variation : ndarray
The calculated variation along the requested axis.

References

[R709]

Examples

```python
>>> from scipy.stats import variation
>>> variation([1, 2, 3, 4, 5])
0.47140452079103173
```

scipy.stats.find_repeats (arr)
Find repeats and repeat counts.

Parameters

\(arr\) : array_like
Input array. This is cast to float64.
Returns  
values : ndarray  
The unique values from the (flattened) input that are repeated.

counts : ndarray  
Number of times the corresponding ‘value’ is repeated.

Notes  
In numpy >= 1.9 numpy.unique provides similar functionality. The main difference is that find_repeats only returns repeated values.

Examples  

```python
>>> from scipy import stats
>>> stats.find_repeats([2, 1, 2, 3, 2, 2, 5])
RepeatedResults(values=array([2.]), counts=array([4]))

>>> stats.find_repeats([[10, 20, 1, 2], [5, 5, 4, 4]])
RepeatedResults(values=array([4., 5.]), counts=array([2, 2]))
```

scipy.stats.trim_mean(a, proportiontocut, axis=0)
Return mean of array after trimming distribution from both tails.

If proportiontocut = 0.1, slices off ‘leftmost’ and ‘rightmost’ 10% of scores. The input is sorted before slicing. Slices off less if proportion results in a non-integer slice index (i.e., conservatively slices off proportiontocut).

Parameters  
a : array_like  
Input array

proportiontocut : float  
Fraction to cut off of both tails of the distribution

axis : int or None, optional  
Axis along which the trimmed means are computed. Default is 0. If None, compute over the whole array a.

Returns  
trim_mean : ndarray  
Mean of trimmed array.

See also:
trimboth  
tmean  
compute the trimmed mean ignoring values outside given limits.

Examples  

```python
>>> from scipy import stats
>>> x = np.arange(20)
9.5
>>> x2 = x.reshape(5, 4)
9.5
>>> x2
array([[ 0, 1, 2, 3],
       [ 4, 5, 6, 7],
       [ 8, 9, 10, 11],
       [12, 13, 14, 15],
       [16, 17, 18, 19]])

>>> stats.trim_mean(x2, 0.25)
array([ 8., 9., 10., 11.])

>>> stats.trim_mean(x2, 0.25, axis=1)
array([ 1.5, 5.5, 9.5, 13.5, 17.5])
```
cumfreq(a[, numbins, defaultreallimits, weights])  Return a cumulative frequency histogram, using the histogram function.

defaultreallimits : tuple (lower, upper), optional
    The lower and upper values for the range of the histogram. If no value is given, a range slightly larger than
    the range of the values in a is used. Specifically (a.min() - s, a.max() + s), where s = (1/2) (a.max() -
    a.min()) / (numbins - 1).

weights : array_like, optional
    The weights for each value in a. Default is None, which gives each value a weight of 1.0

Returns

    cumcount : ndarray
        Binned values of cumulative frequency.

Examples

    >>> import matplotlib.pyplot as plt
    >>> from scipy import stats
    >>> x = [1, 4, 2, 1, 3, 1]
    >>> res = stats.cumfreq(x, numbins=4, defaultreallimits=(1.5, 5))
    >>> res.cumcount
    array([ 1.,  2.,  3.,  3.])
    >>> res.extrapoints
    3

Create a normal distribution with 1000 random values

    >>> rng = np.random.RandomState(seed=12345)
    >>> samples = stats.norm.rvs(size=1000, random_state=rng)

    >>> samples

Calculate cumulative frequencies
```python
>>> res = stats.cumfreq(samples, numbins=25)
Calculate space of values for x
>>> x = res.lowerlimit + np.linspace(0, res.binsize*res.cumcount.size,
...                                res.cumcount.size)
Plot histogram and cumulative histogram
>>> fig = plt.figure(figsize=(10, 4))
>>> ax1 = fig.add_subplot(1, 2, 1)
>>> ax2 = fig.add_subplot(1, 2, 2)
>>> ax1.hist(samples, bins=25)
>>> ax1.set_title('Histogram')
>>> ax2.bar(x, res.cumcount, width=res.binsize)
>>> ax2.set_title('Cumulative histogram')
>>> ax2.set_xlim([x.min(), x.max()])
>>> plt.show()
```

---

**scipy.stats.itemfreq(a)**

Return a 2-D array of item frequencies.

**Parameters**

- `a`: (N,) array_like
  Input array.

**Returns**

- `itemfreq`: (K,) ndarray
  A 2-D frequency table. Column 1 contains sorted, unique values from `a`,
column 2 contains their respective counts.

**Examples**

```python
>>> from scipy import stats
>>> a = np.array([1, 1, 5, 0, 1, 2, 2, 0, 1, 4])
>>> stats.itemfreq(a)
aarray([[ 0.,  2.],
        [ 1.,  4.],
        [ 2.,  2.],
        [ 4.,  1.],
        [ 5.,  1.])
>>> np.bincount(a)
aarray([2, 4, 2, 0, 1, 1])
```
```python
>>> stats.itemfreq(a/10.)
array([[ 0. , 2. ],
       [ 0.1, 4. ],
       [ 0.2, 2. ],
       [ 0.4, 1. ],
       [ 0.5, 1. ]])
```

**scipy.stats.percentileofscore** *(a, score, kind='rank')*

The percentile rank of a score relative to a list of scores.

A percentileofscore of, for example, 80% means that 80% of the scores in `a` are below the given score. In the case of gaps or ties, the exact definition depends on the optional keyword, `kind`.

**Parameters**
- `a`: array_like
  Array of scores to which `score` is compared.
- `score`: int or float
  Score that is compared to the elements in `a`.
- `kind`: {'rank', 'weak', 'strict', 'mean'}, optional
  This optional parameter specifies the interpretation of the resulting score:
  - **'rank'**: Average percentage ranking of score. In case of multiple matches, average the percentage rankings of all matching scores.
  - **'weak'**: This kind corresponds to the definition of a cumulative distribution function. A percentileofscore of 80% means that 80% of values are less than or equal to the provided score.
  - **'strict'**: Similar to 'weak', except that only values that are strictly less than the given score are counted.
  - **'mean'**: The average of the 'weak' and 'strict' scores, often used in testing. See http://en.wikipedia.org/wiki/Percentile_rank

**Returns**
- `pcos`: float
  Percentile-position of score (0-100) relative to `a`.

**See also:**
- `numpy.percentile`

**Examples**

Three-quarters of the given values lie below a given score:

```python
>>> from scipy import stats
>>> stats.percentileofscore([1, 2, 3, 4], 3)
75.0
```

With multiple matches, note how the scores of the two matches, 0.6 and 0.8 respectively, are averaged:

```python
>>> stats.percentileofscore([1, 2, 3, 3, 4], 3)
70.0
```

Only 2/5 values are strictly less than 3:

```python
>>> stats.percentileofscore([1, 2, 3, 4], 3, kind='strict')
40.0
```
But 4/5 values are less than or equal to 3:

```python
>>> stats.percentileofscore([1, 2, 3, 3, 4], 3, kind='weak')
80.0
```

The average between the weak and the strict scores is

```python
>>> stats.percentileofscore([1, 2, 3, 3, 4], 3, kind='mean')
60.0
```

```python
scipy.stats.scoreatpercentile(a, per, limit=(), interpolation_method='fraction', axis=None)
```

Calculate the score at a given percentile of the input sequence.

For example, the score at `per=50` is the median. If the desired quantile lies between two data points, we interpolate between them, according to the value of `interpolation`. If the parameter `limit` is provided, it should be a tuple (lower, upper) of two values.

**Parameters**
- `a`: array_like
  A 1-D array of values from which to extract score.
- `per`: array_like
  Percentile(s) at which to extract score. Values should be in range [0,100].
- `limit`: tuple, optional
  Tuple of two scalars, the lower and upper limits within which to compute the percentile. Values of `a` outside this (closed) interval will be ignored.
- `interpolation_method`: {'fraction', 'lower', 'higher'}, optional
  This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points `i` and `j`
  - fraction: `i + (j - i) * fraction` where `fraction` is the fractional part of the index surrounded by `i` and `j`
  - lower: `i`
  - higher: `j`
- `axis`: int, optional
  Axis along which the percentiles are computed. Default is None. If None, compute over the whole array `a`.

**Returns**
- `score`: float or ndarray
  Score at percentile(s).

**See also:**
- `percentileofscore`, `numpy.percentile`

**Notes**

This function will become obsolete in the future. For Numpy 1.9 and higher, `numpy.percentile` provides all the functionality that `scoreatpercentile` provides. And it’s significantly faster. Therefore it’s recommended to use `numpy.percentile` for users that have numpy >= 1.9.

**Examples**

```python
>>> from scipy import stats
>>> a = np.arange(100)
>>> stats.scoreatpercentile(a, 50)
49.5
```

```python
scipy.stats.relfreq(a, numbins=10, defaultreallimits=None, weights=None)
```

Return a relative frequency histogram, using the histogram function.

A relative frequency histogram is a mapping of the number of observations in each of the bins relative to the total of observations.
Parameters

- **a**: array_like
  
  Input array.

- **numbins**: int, optional
  
  The number of bins to use for the histogram. Default is 10.

- **defaultreallimits**: tuple (lower, upper), optional
  
  The lower and upper values for the range of the histogram. If no value is given, a range slightly larger than the range of the values in `a` is used. Specifically `(a.min() - s, a.max() + s)`, where
  \[
  s = \frac{1}{2} \frac{(a.max() - a.min())}{(numbins - 1)}.
  \]

- **weights**: array_like, optional
  
  The weights for each value in `a`. Default is None, which gives each value a weight of 1.0

Returns

- **frequency**: ndarray
  
  Binned values of relative frequency.

- **lowerlimit**: float
  
  Lower real limit.

- **binsize**: float
  
  Width of each bin.

- **extrapoints**: int
  
  Extra points.

Examples

```python
>>> import matplotlib.pyplot as plt
>>> from scipy import stats

>>> a = np.array([2, 4, 1, 2, 3, 2])
>>> res = stats.relfreq(a, numbins=4)
>>> res.frequency
array([ 0.16666667, 0.5 , 0.16666667, 0.16666667])

>>> np.sum(res.frequency) # relative frequencies should add up to 1
1.0

Create a normal distribution with 1000 random values

```python
>>> rng = np.random.RandomState(seed=12345)
>>> samples = stats.norm.rvs(size=1000, random_state=rng)

Calculate relative frequencies

```python
>>> res = stats.relfreq(samples, numbins=25)

Calculate space of values for x

```python
>>> x = res.lowerlimit + np.linspace(0, res.binsize*res.frequency.size, ...
                                        res.frequency.size)

Plot relative frequency histogram

```python
>>> fig = plt.figure(figsize=(5, 4))
>>> ax = fig.add_subplot(1, 1, 1)
>>> ax.bar(x, res.frequency, width=res.binsize)
>>> ax.set_title('Relative frequency histogram')
>>> ax.set_xlim([x.min(), x.max()])

>>> plt.show()
```
Relative frequency histogram

\[ \begin{array}{c}
0.10 \\
0.08 \\
0.06 \\
0.04 \\
0.02 \\
0.00 \\
\end{array} \]

\begin{array}{c}

\end{array} 

\textbf{binned_statistic}(x, values[, statistic, ...])

- Compute a binned statistic for one or more sets of data.

\textbf{binned_statistic_2d}(x, y, values[, ...])

- Compute a bidimensional binned statistic for one or more sets of data.

\textbf{binned_statistic_dd}(sample, values[, ...])

- Compute a multidimensional binned statistic for a set of data.

\textbf{scipy.stats.binned_statistic}(x, values, statistic='mean', bins=10, range=None)

- Compute a binned statistic for one or more sets of data.

This is a generalization of a histogram function. A histogram divides the space into bins, and returns the count of the number of points in each bin. This function allows the computation of the sum, mean, median, or other statistic of the values (or set of values) within each bin.

**Parameters**

- \textbf{x} : (N,) array_like
  A sequence of values to be binned.

- \textbf{values} : (N,) array_like or list of (N,) array_like
  The data on which the statistic will be computed. This must be the same shape as \textbf{x}, or a set of sequences - each the same shape as \textbf{x}. If \textbf{values} is a set of sequences, the statistic will be computed on each independently.

- \textbf{statistic} : string or callable, optional
  The statistic to compute (default is ‘mean’). The following statistics are available:
  - ‘mean’ : compute the mean of values for points within each bin. Empty bins will be represented by NaN.
  - ‘median’ : compute the median of values for points within each bin. Empty bins will be represented by NaN.
  - ‘count’ : compute the count of points within each bin. This is identical to an unweighted histogram. \textbf{values} array is not referenced.
  - ‘sum’ : compute the sum of values for points within each bin. This is identical to a weighted histogram.
• 'min' : compute the minimum of values for points within each bin. Empty bins will be represented by NaN.
• 'max' : compute the maximum of values for points within each bin. Empty bins will be represented by NaN.
• function : a user-defined function which takes a 1D array of values, and outputs a single numerical statistic. This function will be called on the values in each bin. Empty bins will be represented by function([]), or NaN if this returns an error.

bins : int or sequence of scalars, optional
If bins is an int, it defines the number of equal-width bins in the given range (10 by default). If bins is a sequence, it defines the bin edges, including the rightmost edge, allowing for non-uniform bin widths. Values in x that are smaller than lowest bin edge are assigned to bin number 0, values beyond the highest bin are assigned to bins[-1]. If the bin edges are specified, the number of bins will be, (nx = len(bins)-1).

range : (float, float) or [(float, float)], optional
The lower and upper range of the bins. If not provided, range is simply (x.min(), x.max()). Values outside the range are ignored.

statistic : array
The values of the selected statistic in each bin.

bin_edges : array of dtype float
Return the bin edges (length(statistic)+1).

binnumber : 1-D ndarray of ints
Indices of the bins (corresponding to bin_edges) in which each value of x belongs. Same length as values. A binnumber of i means the corresponding value is between (bin_edges[i-1], bin_edges[i]).

See also:
numpy.digitize, numpy.histogram, binned_statistic_2d, binned_statistic_dd

Notes
All but the last (righthand-most) bin is half-open. In other words, if bins is [1, 2, 3, 4], then the first bin is [1, 2) (including 1, but excluding 2) and the second [2, 3). The last bin, however, is [3, 4], which includes 4.

New in version 0.11.0.

Examples

```python
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

First some basic examples:

Create two evenly spaced bins in the range of the given sample, and sum the corresponding values in each of those bins:

```python
>>> values = [1.0, 1.0, 2.0, 1.5, 3.0]
>>> stats.binned_statistic([1, 1, 2, 5, 7], values, 'sum', bins=2)
(array([ 4. , 4.5]), array([1., 4., 7.]), array([1, 1, 1, 2, 2]))
```

Multiple arrays of values can also be passed. The statistic is calculated on each set independently:

```python
>>> values = [[1.0, 1.0, 2.0, 1.5, 3.0], [2.0, 2.0, 4.0, 3.0, 6.0]]
>>> stats.binned_statistic([[1, 1, 2, 5, 7], values, 'sum', bins=2])
```
As a second example, we now generate some random data of sailing boat speed as a function of wind speed, and then determine how fast our boat is for certain wind speeds:

```python
>>> windspeed = 8 * np.random.rand(500)
>>> boatspeed = .3 * windspeed**.5 + .2 * np.random.rand(500)
>>> bin_means, bin_edges, binnumber = stats.binned_statistic(windspeed,
...     boatspeed, statistic='median', bins=[1,2,3,4,5,6,7])
>>> plt.figure()
>>> plt.plot(windspeed, boatspeed, 'b.', label='raw data')
>>> plt.hlines(bin_means, bin_edges[:-1], bin_edges[1:], colors='g', lw=5,
...     label='binned statistic of data')
>>> plt.legend()
```

Now we can use `binnumber` to select all datapoints with a windspeed below 1:

```python
>>> low_boatspeed = boatspeed[binnumber == 0]
```

As a final example, we will use `bin_edges` and `binnumber` to make a plot of a distribution that shows the mean and distribution around that mean per bin, on top of a regular histogram and the probability distribution function:

```python
>>> x = np.linspace(0, 5, num=500)
>>> x_pdf = stats.maxwell.pdf(x)
>>> samples = stats.maxwell.rvs(size=10000)
>>> bin_means, bin_edges, binnumber = stats.binned_statistic(x, x_pdf,
...     statistic='mean', bins=25)
>>> bin_width = (bin_edges[1] - bin_edges[0])
>>> bin_centers = bin_edges[1:] - bin_width/2
```

```python
>>> plt.figure()
>>> plt.hist(samples, bins=50, normed=True, histtype='stepfilled',
...     alpha=0.2, label='histogram of data')
>>> plt.plot(x, x_pdf, 'r-', label='analytical pdf')
>>> plt.hlines(bin_means, bin_edges[:-1], bin_edges[1:], colors='g', lw=2,
...     label='binned statistic of data')
>>> plt.plot((binnumber - 0.5) * bin_width, x_pdf, 'g.', alpha=0.5)
>>> plt.legend(fontsize=10)
>>> plt.show()
```
```python
scipy.stats.binned_statistic_2d(x, y, values, statistic='mean', bins=10, range=None, expand_binnumbers=False)
```

Compute a bidimensional binned statistic for one or more sets of data.

This is a generalization of a histogram2d function. A histogram divides the space into bins, and returns the count of the number of points in each bin. This function allows the computation of the sum, mean, median, or other statistic of the values (or set of values) within each bin.

**Parameters**

- `x` : (N,) array_like
  
  A sequence of values to be binned along the first dimension.

- `y` : (N,) array_like
  
  A sequence of values to be binned along the second dimension.

- `values` : (N,) array_like or list of (N,) array_like
  
  The data on which the statistic will be computed. This must be the same shape as `x`, or a list of sequences - each with the same shape as `x`. If `values` is such a list, the statistic will be computed on each independently.

- `statistic` : string or callable, optional
The statistic to compute (default is ‘mean’). The following statistics are available:

- ‘mean’: compute the mean of values for points within each bin. Empty bins will be represented by NaN.
- ‘median’: compute the median of values for points within each bin. Empty bins will be represented by NaN.
- ‘count’: compute the count of points within each bin. This is identical to an unweighted histogram. values array is not referenced.
- ‘sum’: compute the sum of values for points within each bin. This is identical to a weighted histogram.
- ‘min’: compute the minimum of values for points within each bin. Empty bins will be represented by NaN.
- ‘max’: compute the maximum of values for points within each bin. Empty bins will be represented by NaN.
- ‘function’: a user-defined function which takes a 1D array of values, and outputs a single numerical statistic. This function will be called on the values in each bin. Empty bins will be represented by function([]), or NaN if this returns an error.

\[ \text{bins} \, : \, \text{int or [int, int] or array_like or [array, array], optional} \]

The bin specification:

- the number of bins for the two dimensions (nx = ny = bins),
- the number of bins in each dimension (nx, ny = bins),
- the bin edges for the two dimensions (x_edge = y_edge = bins),
- the bin edges in each dimension (x_edge, y_edge = bins).

If the bin edges are specified, the number of bins will be, (nx = len(x_edge)-1, ny = len(y_edge)-1).

\[ \text{range} \, : \, (2,2) \, \text{array_like, optional} \]

The leftmost and rightmost edges of the bins along each dimension (if not specified explicitly in the bins parameters): [[xmin, xmax], [ymin, ymax]]. All values outside of this range will be considered outliers and not tallied in the histogram.

\[ \text{expand_binnumbers} \, : \, \text{bool, optional} \]

‘False’ (default): the returned binnumber is a shape (N,) array of linearized bin indices. ‘True’: the returned binnumber is ‘unraveled’ into a shape (2,N) ndarray, where each row gives the bin numbers in the corresponding dimension. See the binnumber returned value, and the Examples section.

\[ \text{Returns} \]

\[ \text{statistic} \, : \, (nx, ny) \, \text{ndarray} \]

The values of the selected statistic in each two-dimensional bin.

\[ \text{x_edge} \, : \, (nx + 1) \, \text{ndarray} \]

The bin edges along the first dimension.

\[ \text{y_edge} \, : \, (ny + 1) \, \text{ndarray} \]

The bin edges along the second dimension.

\[ \text{binnumber} \, : \, (N,) \, \text{array of ints or (2,N) \, \text{ndarray of ints}} \]

This assigns to each element of sample an integer that represents the bin in which this observation falls. The representation depends on the expand_binnumbers argument. See Notes for details.

See also:

numpy.digitize, numpy.histogram2d, binned_statistic, binned_statistic_dd

Notes

Binedges: All but the last (righthand-most) bin is half-open. In other words, if bins is [1, 2, 3, 4], then the first bin is [1, 2) (including 1, but excluding 2) and the second [2, 3). The last bin, however, is [3, 4], which includes 4.
Scientific Python Reference Guide, Release 1.0.0

**binnumber**: This returned argument assigns to each element of `sample` an integer that represents the bin in which it belongs. The representation depends on the `expand_binnumbers` argument. If ‘False’ (default): The returned `binnumber` is a shape (N,) array of linearized indices mapping each element of `sample` to its corresponding bin (using row-major ordering). If ‘True’: The returned `binnumber` is a shape (2,N) ndarray where each row indicates bin placements for each dimension respectively. In each dimension, a `binnumber` of `i` means the corresponding value is between `(D_edge[i-1], D_edge[i])`, where ‘D’ is either ‘x’ or ‘y’.

New in version 0.11.0.

**Examples**

```python
>>> from scipy import stats

Calculate the counts with explicit bin-edges:

```python
>>> x = [0.1, 0.1, 0.1, 0.6]
>>> y = [2.1, 2.6, 2.1, 2.1]
>>> binx = [0.0, 0.5, 1.0]
>>> biny = [2.0, 2.5, 3.0]
>>> ret = stats.binned_statistic_2d(x, y, None, 'count', bins=[binx,biny])
>>> ret.statistic
array([[ 2.,  1.],
        [ 1.,  0.]])

The bin in which each sample is placed is given by the `binnumber` returned parameter. By default, these are the linearized bin indices:

```python
>>> ret.binnumber
array([5, 6, 5, 9])
```

The bin indices can also be expanded into separate entries for each dimension using the `expand_binnumbers` parameter:

```python
>>> ret = stats.binned_statistic_2d(x, y, None, 'count', bins=[binx,biny],
                       expand_binnumbers=True)
>>> ret.binnumber
array([[1, 1, 1, 2],
        [1, 2, 1, 1]])
```

Which shows that the first three elements belong in the xbin 1, and the fourth into xbin 2; and so on for y.

### scipy.stats.binned_statistic_dd(sample, values, statistic='mean', bins=10, range=None, expand_binnumbers=False)

Compute a multidimensional binned statistic for a set of data.

This is a generalization of a histogramdd function. A histogram divides the space into bins, and returns the count of the number of points in each bin. This function allows the computation of the sum, mean, median, or other statistic of the values within each bin.

**Parameters**
- `sample` : array_like
  Data to histogram passed as a sequence of D arrays of length N, or as an (N,D) array.
- `values` : (N,) array_like or list of (N,) array_like
  The data on which the statistic will be computed. This must be the same shape as x, or a list of sequences - each with the same shape as x. If `values` is such a list, the statistic will be computed on each independently.
- `statistic` : string or callable, optional
  The statistic to compute (default is ‘mean’). The following statistics are available:
SciPy Reference Guide, Release 1.0.0

**mean** : compute the mean of values for points within each bin. Empty bins will be represented by NaN.

**median** : compute the median of values for points within each bin. Empty bins will be represented by NaN.

**count** : compute the count of points within each bin. This is identical to an unweighted histogram. values array is not referenced.

**sum** : compute the sum of values for points within each bin. This is identical to a weighted histogram.

**min** : compute the minimum of values for points within each bin. Empty bins will be represented by NaN.

**max** : compute the maximum of values for point within each bin. Empty bins will be represented by NaN.

**function** : a user-defined function which takes a 1D array of values, and outputs a single numerical statistic. This function will be called on the values in each bin. Empty bins will be represented by function([]), or NaN if this returns an error.

**bins** : sequence or int, optional

The bin specification must be in one of the following forms:

- A sequence of arrays describing the bin edges along each dimension.
- The number of bins for each dimension \((nx, ny, ..., = bins)\).
- The number of bins for all dimensions \((nx = ny = ... = bins)\).

**range** : sequence, optional

A sequence of lower and upper bin edges to be used if the edges are not given explicitly in \(bins\). Defaults to the minimum and maximum values along each dimension.

**expand_binnumbers** : bool, optional

- ‘False’ (default): the returned \(binnumber\) is a shape \((N,)\) array of linearized bin indices. ‘True’: the returned \(binnumber\) is ‘unraveled’ into a shape \((D,N)\) ndarray, where each row gives the bin numbers in the corresponding dimension. See the \(binnumber\) returned value, and the Examples section of \(binned_statistic_2d\).

**Returns**

**statistic** : ndarray, shape(nx1, nx2, nx3,...)

The values of the selected statistic in each two-dimensional bin.

**bin_edges** : list of ndarrays

A list of D arrays describing the \((nxi + 1)\) bin edges for each dimension.

**binnumber** : \((N,)\) array of ints or \((D,N)\) ndarray of ints

This assigns to each element of \(sample\) an integer that represents the bin in which this observation falls. The representation depends on the \(expand_binnumbers\) argument. See Notes for details.

See also:

numpy.digitize, numpy.histogramdd, binned_statistic, binned_statistic_2d

**Notes**

Binedges: All but the last (righthand-most) bin is half-open in each dimension. In other words, if \(bins\) is \([1, 2, 3, 4]\), then the first bin is \([1, 2)\) (including 1, but excluding 2) and the second \([2, 3)\). The last bin, however, is \([3, 4]\), which includes 4.

**binnumber**: This returned argument assigns to each element of \(sample\) an integer that represents the bin in which it belongs. The representation depends on the \(expand_binnumbers\) argument. If ‘False’ (default): The returned \(binnumber\) is a shape \((N,)\) array of linearized indices mapping each element of \(sample\) to its corresponding bin (using row-major ordering). If ‘True’: The returned \(binnumber\) is a shape \((D,N)\) ndarray where each row indicates bin placements for each dimension respectively. In each dimension, a binnumber of \(i\) means the corresponding value is between \((\text{bin_edges}[D][i-1], \text{bin_edges}[D][i])\), for each dimension ‘D’.

1984 Chapter 5. API Reference
New in version 0.11.0.

**obrientransform(*args)**

Compute the O’Brien transform on input data (any number of arrays).

**bayes_mvs(data[, alpha])**

Bayesian confidence intervals for the mean, var, and std.

**mvsdist(data)**

‘Frozen’ distributions for mean, variance, and standard deviation of data.

**sem(a[, axis, ddof, nan_policy])**

Calculate the standard error of the mean (or standard error of measurement) of the values in the input array.

**zmap(scores, compare[, axis, ddof])**

Calculate the relative z-scores.

**zscore(a[, axis, ddof])**

Calculate the z score of each value in the sample, relative to the sample mean and standard deviation.

**iqr(x[, axis, rng, scale, nan_policy, ...])**

Compute the interquartile range of the data along the specified axis.

---

**scipy.stats.obrientransform(*args)**

Compute the O’Brien transform on input data (any number of arrays).

Used to test for homogeneity of variance prior to running one-way stats. Each array in *args is one level of a factor. If _f_oneway_ is run on the transformed data and found significant, the variances are unequal. From Maxwell and Delaney [R677], p.112.

**Parameters**

* args : tuple of array_like
  Any number of arrays.

**Returns**

* obrientransform : ndarray
  Transformed data for use in an ANOVA. The first dimension of the result corresponds to the sequence of transformed arrays. If the arrays given are all 1-D of the same length, the return value is a 2-D array; otherwise it is a 1-D array of type object, with each element being an ndarray.

**References**

[R677]

**Examples**

We’ll test the following data sets for differences in their variance.

```python
>>> x = [10, 11, 13, 9, 7, 12, 12, 9, 10]
>>> y = [13, 21, 5, 10, 8, 14, 10, 12, 7, 15]
```

Apply the O’Brien transform to the data.

```python
>>> from scipy.stats import obrientransform
>>> tx, ty = obrientransform(x, y)
```

Use _scipy.stats.f_oneway_ to apply a one-way ANOVA test to the transformed data.

```python
>>> from scipy.stats import f_oneway
>>> F, p = f_oneway(tx, ty)
>>> p
0.1314139477040335
```

If we require that _p < 0.05_ for significance, we cannot conclude that the variances are different.

**scipy.stats.bayes_mvs(data, alpha=0.9)**

Bayesian confidence intervals for the mean, var, and std.
**Parameters**

- **data**: array_like
  Input data, if multi-dimensional it is flattened to 1-D by `bayes_mvs`. Requires 2 or more data points.
- **alpha**: float, optional
  Probability that the returned confidence interval contains the true parameter.

**Returns**

- **mean_cntr, var_cntr, std_cntr**: tuple
  The three results are for the mean, variance and standard deviation, respectively. Each result is a tuple of the form:

  ```
  (center, (lower, upper))
  ```

  with `center` the mean of the conditional pdf of the value given the data, and `(lower, upper)` a confidence interval, centered on the median, containing the estimate to a probability `alpha`.

**See also:**

`mvsdist`

**Notes**

Each tuple of mean, variance, and standard deviation estimates represent the `(center, (lower, upper))` with center the mean of the conditional pdf of the value given the data and `(lower, upper)` a confidence interval centered on the median, containing the estimate to a probability `alpha`.

Converts data to 1-D and assumes all data has the same mean and variance. Uses Jeffrey’s prior for variance and std.

**Equivalent to**

```python
tuple((x.mean(), x.interval(alpha)) for x in mvsdist(dat))
```

**References**

**Examples**

First a basic example to demonstrate the outputs:

```python
>>> from scipy import stats
>>> data = [6, 9, 12, 7, 8, 8, 13]
>>> mean, var, std = stats.bayes_mvs(data)
>>> mean
Mean(statistic=9.0, minmax=(7.1036502226125329, 10.896349777387467))
>>> var
Variance(statistic=10.0, minmax=(3.176724206..., 24.45910382...))
>>> std
Std_dev(statistic=2.9724954732045084, minmax=(1.7823367265645143, 4.˓→9456146050146295))
```

Now we generate some normally distributed random data, and get estimates of mean and standard deviation with 95% confidence intervals for those estimates:

```python
>>> n_samples = 100000
>>> data = stats.norm.rvs(size=n_samples)
>>> res_mean, res_var, res_std = stats.bayes_mvs(data, alpha=0.95)
```

```python
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
```
```python
>>> ax.hist(data, bins=100, normed=True, label='Histogram of data')
>>> ax.vlines(res_mean.statistic, 0, 0.5, colors='r', label='Estimated mean')
>>> ax.axvspan(res_mean.minmax[0], res_mean.minmax[1], facecolor='r',
...           alpha=0.2, label=r'Estimated mean (95% limits)')
>>> ax.vlines(res_std.statistic, 0, 0.5, colors='g', label='Estimated scale')
>>> ax.axvspan(res_std.minmax[0], res_std.minmax[1], facecolor='g', alpha=0.2,
...           label=r'Estimated scale (95% limits)')
>>> ax.legend(fontsize=10)
>>> ax.set_xlim([-4, 4])
>>> ax.set_ylim([0, 0.5])
>>> plt.show()
```

**scipy.stats.mvsdist** *(data)*

‘Frozen’ distributions for mean, variance, and standard deviation of data.

**Parameters**
- **data**: array_like
  Input array. Converted to 1-D using ravel. Requires 2 or more data-points.

**Returns**
- **mdist**: “frozen” distribution object
  Distribution object representing the mean of the data
- **vdist**: “frozen” distribution object
  Distribution object representing the variance of the data
- **sdist**: “frozen” distribution object
  Distribution object representing the standard deviation of the data

**See also**
- **bayes_mvs**

**Notes**

The return values from `bayes_mvs(data)` is equivalent to `tuple((x.mean(), x.interval(0.90)) for x in mvsdist(data))`.

In other words, calling `<dist>.mean()` and `<dist>.interval(0.90)` on the three distribution objects returned from this function will give the same results that are returned from `bayes_mvs`. 
References

Examples

```python
>>> from scipy import stats
>>> data = [6, 9, 12, 7, 8, 8, 13]
>>> mean, var, std = stats.mvsdist(data)
```

We now have frozen distribution objects “mean”, “var” and “std” that we can examine:

```python
>>> mean.mean()
9.0
>>> mean.interval(0.95)
(6.6120585482655692, 11.387941451734431)
>>> mean.std()
1.1952286093343936
```

```python
scipy.stats.sem(a, axis=0, ddof=1, nan_policy='propagate')
```

Calculate the standard error of the mean (or standard error of measurement) of the values in the input array.

**Parameters**
- `a`: array_like
  - An array containing the values for which the standard error is returned.
- `axis`: int or None, optional
  - Axis along which to operate. Default is 0. If None, compute over the whole array `a`.
- `ddof`: int, optional
  - Delta degrees-of-freedom. How many degrees of freedom to adjust for bias in limited samples relative to the population estimate of variance. Defaults to 1.
- `nan_policy`: {'propagate', 'raise', 'omit'}, optional
  - Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default is ‘propagate’.

**Returns**
- `s`: ndarray or float
  - The standard error of the mean in the sample(s), along the input axis.

**Notes**
The default value for `ddof` is different to the default (0) used by other ddof containing routines, such as np.std and np.nanstd.

**Examples**
Find standard error along the first axis:

```python
>>> from scipy import stats
>>> a = np.arange(20).reshape(5,4)
>>> stats.sem(a)
array([ 2.8284, 2.8284, 2.8284, 2.8284])
```

Find standard error across the whole array, using n degrees of freedom:

```python
>>> stats.sem(a, axis=None, ddof=0)
1.2893796958227628
```
scipy.stats.zmap(scores, compare, axis=0, ddof=0)
Calculate the relative z-scores.

Return an array of z-scores, i.e., scores that are standardized to zero mean and unit variance, where mean and variance are calculated from the comparison array.

Parameters:
- **scores**: array_like
  The input for which z-scores are calculated.
- **compare**: array_like
  The input from which the mean and standard deviation of the normalization are taken; assumed to have the same dimension as scores.
- **axis**: int or None, optional
  Axis over which mean and variance of compare are calculated. Default is 0. If None, compute over the whole array scores.
- **ddof**: int, optional
  Degrees of freedom correction in the calculation of the standard deviation. Default is 0.

Returns:
- **zscore**: array_like
  Z-scores, in the same shape as scores.

Notes
This function preserves ndarray subclasses, and works also with matrices and masked arrays (it uses asanyarray instead of asarray for parameters).

Examples

```python
>>> from scipy.stats import zmap
>>> a = [0.5, 2.0, 2.5, 3]
>>> b = [0, 1, 2, 3, 4]
>>> zmap(a, b)
array([-1.06066017, 0.0, 0.35355339, 0.70710678])
```

scipy.stats.zscore(a, axis=0, ddof=0)
Calculate the z score of each value in the sample, relative to the sample mean and standard deviation.

Parameters:
- **a**: array_like
  An array like object containing the sample data.
- **axis**: int or None, optional
  Axis along which to operate. Default is 0. If None, compute over the whole array a.
- **ddof**: int, optional
  Degrees of freedom correction in the calculation of the standard deviation. Default is 0.

Returns:
- **zscore**: array_like
  The z-scores, standardized by mean and standard deviation of input array a.

Notes
This function preserves ndarray subclasses, and works also with matrices and masked arrays (it uses asanyarray instead of asarray for parameters).

Examples

```python
>>> a = np.array([ 0.7972, 0.0767, 0.4383, 0.7866, 0.8091,
... 0.1954, 0.6307, 0.6599, 0.1065, 0.0508])
>>> from scipy import stats
>>> stats.zscore(a)
```

5.27. Statistical functions (scipy.stats)
Computing along a specified axis, using n-1 degrees of freedom (ddof=1) to calculate the standard deviation:

```python
>>> b = np.array([[ 0.3148, 0.0478, 0.6243, 0.4608],
                [ 0.7149, 0.0775, 0.6072, 0.9656],
                [ 0.6341, 0.1403, 0.9759, 0.4064],
                [ 0.9021, 0.2481, 0.1188, 0.1366]])
>>> stats.zscore(b, axis=1, ddof=1)
array([-0.19264823, -1.28415119, 1.07259584, 0.40420358],
       [ 0.33048416, -1.37380874, 0.04251374, 1.00081084],
       [ 0.26796377, -1.12598418, 1.23283094, -0.37481053],
       [-0.22095197, 0.24468594, 1.19042819, -1.21416216]])
```

SciPy Reference Guide, Release 1.0.0

```python
scipy.stats.iqr(x, axis=None, rng=(25, 75), scale='raw', nan_policy='propagate', interpolation='linear', keepdims=False)
```

**Parameters**

- `x`: array_like
  Input array or object that can be converted to an array.

- `axis`: int or sequence of int, optional
  Axis along which the range is computed. The default is to compute the IQR for the entire array.

- `rng`: Two-element sequence containing floats in range of [0,100] optional
  Percentiles over which to compute the range. Each must be between 0 and 100, inclusive. The default is the true IQR: (25, 75). The order of the elements is not important.

- `scale`: scalar or str, optional
  The numerical value of scale will be divided out of the final result. The following string values are recognized:
  - `‘raw’`: No scaling, just return the raw IQR. ‘normal’: Scale by $2\sqrt{2\pi}f^{-1}(\frac{1}{2}) \approx 1.349$.
  - `‘true’`: Scale by $2\sqrt{2\pi}f^{-1}(\frac{1}{2}) \approx 1.349$.

- `nan_policy`: {'propagate', 'raise', 'omit'}, optional
  Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default is ‘propagate’.

- `interpolation`: {'linear', 'lower', 'higher', 'midpoint', 'nearest'}, optional
  Specifies the interpolation method to use when the percentile boundaries lie between two data points $i$ and $j$.
SciPy Reference Guide, Release 1.0.0

5.27. Statistical functions (scipy.stats) 1991

• 'linear': \[i + (j - i) \times \text{fraction}\], where \text{fraction} is the fractional part of the index surrounded by \text{i} and \text{j}.
• 'lower': \text{i}.
• 'higher': \text{j}.
• 'nearest': \text{i} or \text{j} whichever is nearest.

Default is 'linear'.

**keepdims**: bool, optional

If this is set to True, the reduced axes are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the original array \text{x}.

**Returns**

• **iqr**: scalar or ndarray

  If \text{axis}=\text{None}, a scalar is returned. If the input contains integers or floats of smaller precision than np.float64, then the output data-type is np.float64. Otherwise, the output data-type is the same as that of the input.

See also:

numpy.std, numpy.var

Notes

This function is heavily dependent on the version of numpy that is installed. Versions greater than 1.11.0b3 are highly recommended, as they include a number of enhancements and fixes to numpy.percentile and numpy.nanpercentile that affect the operation of this function. The following modifications apply:

**Below 1.10.0** [\text{nan_policy} is poorly defined.] The default behavior of numpy.percentile is used for ‘propagate’. This is a hybrid of ‘omit’ and ‘propagate’ that mostly yields a skewed version of ‘omit’ since NaNs are sorted to the end of the data. A warning is raised if there are NaNs in the data.

**Below 1.9.0**: numpy.nanpercentile does not exist.

This means that numpy.percentile is used regardless of \text{nan_policy} and a warning is issued. See previous item for a description of the behavior.

**Below 1.9.0**: keepdims and interpolation are not supported.

The keywords get ignored with a warning if supplied with non-default values. However, multiple axes are still supported.

Examples

```python
>>> from scipy.stats import iqr
>>> x = np.array([[10, 7, 4], [3, 2, 1]])
>>> x
array([[10, 7, 4],
       [3, 2, 1]])
>>> iqr(x)
4.0
>>> iqr(x, axis=0)
array([ 3.5, 2.5, 1.5])
>>> iqr(x, axis=1)
array([[ 3.],
       [ 1.]])
>>> iqr(x, axis=1, keepdims=True)
array([[ 3.],
       [ 1.]])
```

**sigmaclip(a[, low, high])** Iterative sigma-clipping of array elements.

**trimboth(a, proportiontocut[, axis])** Slices off a proportion of items from both ends of an array.

Continued on next page
Table 5.294 – continued from previous page

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>triml(a, proportiontocut[, tail, axis])</code></td>
<td>Slices off a proportion from ONE end of the passed array distribution.</td>
</tr>
</tbody>
</table>

scipy.stats.**sigmclip** \((a, low=4.0, high=4.0)\)
Iterative sigma-clipping of array elements.

The output array contains only those elements of the input array \(c\) that satisfy the conditions

<table>
<thead>
<tr>
<th>Condition</th>
</tr>
</thead>
</table>
| \[
\text{mean}(c) - \text{std}(c) \times \text{low} < c < \text{mean}(c) + \text{std}(c) \times \text{high}
\]

Starting from the full sample, all elements outside the critical range are removed. The iteration continues with a new critical range until no elements are outside the range.

**Parameters**

- **a**: array_like
  Data array, will be raveled if not 1-D.

- **low**: float, optional
  Lower bound factor of sigma clipping. Default is 4.

- **high**: float, optional
  Upper bound factor of sigma clipping. Default is 4.

**Returns**

- **clipped**: ndarray
  Input array with clipped elements removed.

- **lower**: float
  Lower threshold value use for clipping.

- **upper**: float
  Upper threshold value use for clipping.

**Examples**

```python
>>> from scipy.stats import sigmaclip
>>> a = np.concatenate((np.linspace(9.5, 10.5, 31), ...
... np.linspace(-100, 5, 10)))
>>> fact = 1.5
>>> c, low, upp = sigmaclip(a, fact, fact)
>>> c
array([ 9.96666667, 10. , 10.03333333, 10. ])
>>> c.var(), c.std()
(0.00055555555555555165, 0.023570226039551501)
>>> low, c.mean() - fact*c.std(), c.min()
(9.964644646609406727, 9.96464466666666666666)
>>> upp, c.mean() + fact*c.std(), c.max()
(10.035355339059327, 10.035355339059327, 10.035355339059327)
```

```python
>>> a = np.concatenate((np.linspace(9.5, 10.5, 11), ...
... np.linspace(-100, 50, 3)))
>>> c, low, upp = sigmaclip(a, 1.8, 1.8)
>>> (c == np.linspace(9.5, 10.5, 11)).all()
True
```

scipy.stats.**trimboth** \((a, proportiontocut, axis=0)\)
Slices off a proportion of items from both ends of an array.

Slices off the passed proportion of items from both ends of the passed array (i.e., with \(proportiontocut = 0.1\), slices leftmost 10% and rightmost 10% of scores). The trimmed values are the lowest and highest ones. Slices off less if proportion results in a non-integer slice index (i.e., conservatively slices off 'proportiontocut').

**Parameters**

- **a**: array_like
  Data to trim.
**proportiontocut** : float
Proportion (in range 0-1) of total data set to trim of each end.

**axis** : int or None, optional
Axis along which to trim data. Default is 0. If None, compute over the whole array a.

**Returns**

**out** : ndarray
Trimmed version of array a. The order of the trimmed content is undefined.

See also:

`trim_mean`

**Examples**

```python
>>> from scipy import stats
>>> a = np.arange(20)
>>> b = stats.trimboth(a, 0.1)
>>> b.shape
(16,)
```

scipy.stats.trim1(a, proportiontocut, tail='right', axis=0)

Slices off a proportion from ONE end of the passed array distribution.

If `proportiontocut = 0.1`, slices off ‘leftmost’ or ‘rightmost’ 10% of scores. The lowest or highest values are trimmed (depending on the tail). Slices off less if proportion results in a non-integer slice index (i.e., conservatively slices off `proportiontocut`).

**Parameters**

- **a** : array_like
  Input array

- **proportiontocut** : float
  Fraction to cut off of ‘left’ or ‘right’ of distribution

- **tail** : {'left', 'right'}, optional
  Defaults to 'right'.

- **axis** : int or None, optional
  Axis along which to trim data. Default is 0. If None, compute over the whole array a.

**Returns**

**trim1** : ndarray
Trimmed version of array a. The order of the trimmed content is undefined.

scipy.stats.f_oneway(*args)

Performs a 1-way ANOVA.

The one-way ANOVA tests the null hypothesis that two or more groups have the same population mean. The
test is applied to samples from two or more groups, possibly with differing sizes.

**Parameters**

sample1, sample2, ... : array_like

The sample measurements for each group.

**Returns**

statistic : float

The computed F-value of the test.

pvalue : float

The associated p-value from the F-distribution.

**Notes**

The ANOVA test has important assumptions that must be satisfied in order for the associated p-value to be valid.

1. The samples are independent.
2. Each sample is from a normally distributed population.
3. The population standard deviations of the groups are all equal. This property is known as homoscedasticity.

If these assumptions are not true for a given set of data, it may still be possible to use the Kruskal-Wallis H-test (`scipy.stats.kruskal`) although with some loss of power.

The algorithm is from Heiman[2], pp.394-7.

**Examples**

```python
>>> import scipy.stats as stats

[R635] Here are some data on a shell measurement (the length of the anterior adductor muscle scar, standardized by dividing by length) in the mussel Mytilus trossulus from five locations: Tillamook, Oregon; Newport, Oregon; Petersburg, Alaska; Magadan, Russia; and Tvarminne, Finland, taken from a much larger data set used in McDonald et al. (1991).

```python
>>> tillamook = [0.0571, 0.0813, 0.0831, 0.0976, 0.0817, 0.0859, 0.0735,...
               0.0659, 0.0923, 0.0836]
>>> newport = [0.0873, 0.0662, 0.0672, 0.0819, 0.0749, 0.0649, 0.0835,...
               0.0725]
>>> petersburg = [0.0974, 0.1352, 0.0817, 0.1016, 0.0968, 0.1064, 0.105]  
>>> magadan = [0.1033, 0.0915, 0.0781, 0.0685, 0.0677, 0.0697, 0.0764,...
               0.0689]
>>> tvarminne = [0.0703, 0.1026, 0.0956, 0.0973, 0.1039, 0.1045]  
>>> stats.f_oneway(tillamook, newport, petersburg, magadan, tvarminne)
(7.1210194716424473, 0.00028122423145345439)
```
SciPy Reference Guide, Release 1.0.0

y : (N,) array_like
Input

Returns
r : float
Pearson’s correlation coefficient
p-value : float
2-tailed p-value

Notes
The correlation coefficient is calculated as follows:

\[ r_{pb} = \frac{\sum(x - \bar{x})(y - \bar{y})}{\sqrt{\sum(x - \bar{x})^2(y - \bar{y})^2}} \]

where \( \bar{x} \) is the mean of the vector \( x \) and \( \bar{y} \) is the mean of the vector \( y \).

http://www.statsoft.com/textbook/glosp.html#Pearson%20Correlation

Examples

```python
>>> from scipy import stats
>>> a = np.array([0, 0, 0, 1, 1, 1, 1])
>>> b = np.arange(7)
>>> stats.pearsonr(a, b)
(0.8660254037844386, 0.011724811003954654)
>>> stats.pearsonr([1,2,3,4,5], [5,6,7,8,7])
(0.83205029433784372, 0.080509573298498519)
```

scipy.stats.spearmanr(a, b=None, axis=0, nan_policy='propagate')

Calculate a Spearman rank-order correlation coefficient and the p-value to test for non-correlation.

The Spearman correlation is a nonparametric measure of the monotonicity of the relationship between two datasets. Unlike the Pearson correlation, the Spearman correlation does not assume that both datasets are normally distributed. Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply an exact monotonic relationship. Positive correlations imply that as \( x \) increases, so does \( y \). Negative correlations imply that as \( x \) increases, \( y \) decreases.

The p-value roughly indicates the probability of an uncorrelated system producing datasets that have a Spearman correlation at least as extreme as the one computed from these datasets. The p-values are not entirely reliable but are probably reasonable for datasets larger than 500 or so.

Parameters

- a, b : 1D or 2D array_like, b is optional
  One or two 1-D or 2-D arrays containing multiple variables and observations. When these are 1-D, each represents a vector of observations of a single variable. For the behavior in the 2-D case, see under axis, below. Both arrays need to have the same length in the axis dimension.

- axis : int or None, optional
  If axis=0 (default), then each column represents a variable, with observations in the rows. If axis=1, the relationship is transposed: each row represents a variable, while the columns contain observations. If axis=None, then both arrays will be raveled.

- nan_policy : {'propagate', 'raise', 'omit'}, optional
  Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default is ‘propagate’.

Returns
correlation : float or ndarray (2-D square)
Spearman correlation matrix or correlation coefficient (if only 2 variables are given as parameters. Correlation matrix is square with length equal to total number of variables (columns or rows) in a and b combined.

\[ \text{pvalue} : \text{float} \]

The two-sided p-value for a hypothesis test whose null hypothesis is that two sets of data are uncorrelated, has same dimension as rho.

**Notes**

Changes in scipy 0.8.0: rewrite to add tie-handling, and axis.

**References**

[R699]

**Examples**

```python
>>> from scipy import stats
>>> stats.spearmanr([1,2,3,4,5], [5,6,7,8,7])

```

scipy.stats.\texttt{pointbiserialr}(x, y)

Calculate a point biserial correlation coefficient and its p-value.

The point biserial correlation is used to measure the relationship between a binary variable, x, and a continuous variable, y. Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply a determinative relationship.
This function uses a shortcut formula but produces the same result as `pearsonr`.

**Parameters**

- **x**: array_like of bools
  Input array.
- **y**: array_like

**Returns**

- **correlation**: float
  R value
- **pvalue**: float
  2-tailed p-value

**Notes**

`pointbiserialr` uses a t-test with \(n-1\) degrees of freedom. It is equivalent to `pearsonr`.

The value of the point-biserial correlation can be calculated from:

\[
 r_{pb} = \frac{\bar{Y}_1 - \bar{Y}_0}{s_y \sqrt{\frac{N_1 N_2}{N(N-1)}}}
\]

Where \(\bar{Y}_0\) and \(\bar{Y}_1\) are means of the metric observations coded 0 and 1 respectively; \(N_0\) and \(N_1\) are number of observations coded 0 and 1 respectively; \(N\) is the total number of observations and \(s_y\) is the standard deviation of all the metric observations.

A value of \(r_{pb}\) that is significantly different from zero is completely equivalent to a significant difference in means between the two groups. Thus, an independent groups t Test with \(N-2\) degrees of freedom may be used to test whether \(r_{pb}\) is nonzero. The relation between the t-statistic for comparing two independent groups and \(r_{pb}\) is given by:

\[
t = \sqrt{N-2} \frac{r_{pb}}{\sqrt{1-r_{pb}^2}}
\]

**References**

[R679], [R680], [R681]

**Examples**

```python
>>> from scipy import stats
>>> a = np.array([0, 0, 0, 1, 1, 1, 1])
>>> b = np.arange(7)
>>> stats.pointbiserialr(a, b)
(0.8660254037844386, 0.011724811003954652)
>>> stats.pearsonr(a, b)
(0.86602540378443871, 0.011724811003954626)
>>> np.corrcoef(a, b)
array([[ 1. , 0.8660254],
       [ 0.8660254, 1. ]])
```

Scipy.stats.kendalltau(x, y, initial_lexsort=None, nan_policy='propagate')

Calculate Kendall’s tau, a correlation measure for ordinal data.

Kendall’s tau is a measure of the correspondence between two rankings. Values close to 1 indicate strong agreement, values close to -1 indicate strong disagreement. This is the 1945 “tau-b” version of Kendall’s tau [R655], which can account for ties and which reduces to the 1938 “tau-a” version [R654] in absence of ties.

**Parameters**

- **x, y**: array_like
  Arrays of rankings, of the same shape. If arrays are not 1-D, they will be flattened to 1-D.
**initial_lexsort** : bool, optional
Unused (deprecated).

**nan_policy** : {'propagate', 'raise', 'omit'}, optional
Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default is ‘propagate’. Note that if the input contains nan ‘omit’ delegates to mstats_basic.kendalltau(), which has a different implementation.

**Returns**

**correlation** : float
The tau statistic.

**pvalue** : float
The two-sided p-value for a hypothesis test whose null hypothesis is an absence of association, tau = 0.

See also:

**spearmanr** Calculates a Spearman rank-order correlation coefficient.

**theilslopes** Computes the Theil-Sen estimator for a set of points (x, y).

**weightedtau** Computes a weighted version of Kendall’s tau.

**Notes**

The definition of Kendall’s tau that is used is [R655]:

\[
\tau = \frac{P - Q}{\sqrt{(P + Q + T) \times (P + Q + U)}}
\]

where P is the number of concordant pairs, Q the number of discordant pairs, T the number of ties only in x, and U the number of ties only in y. If a tie occurs for the same pair in both x and y, it is not added to either T or U.

**References**

[R654], [R655], [R656], [R657]

**Examples**

```python
>>> from scipy import stats
datax = [12, 2, 1, 12, 2]
datay = [1, 4, 7, 1, 0]
>>> tau, p_value = stats.kendalltau(datax, datay)
>>> tau
-0.47140452079103173
>>> p_value
0.2827454599327748
```

**scipy.stats.weightedtau** *(x, y, rank=True, weigher=None, additive=True)*

Compute a weighted version of Kendall’s \(\tau\).

The weighted \(\tau\) is a weighted version of Kendall’s \(\tau\) in which exchanges of high weight are more influential than exchanges of low weight. The default parameters compute the additive hyperbolic version of the index, \(\tau_h\), which has been shown to provide the best balance between important and unimportant elements [R712].

The weighting is defined by means of a rank array, which assigns a nonnegative rank to each element, and a weigher function, which assigns a weight based from the rank to each element. The weight of an exchange is then the sum or the product of the weights of the ranks of the exchanged elements. The default parameters compute \(\tau_h\): an exchange between elements with rank \(r\) and \(s\) (starting from zero) has weight \(1/(r + 1) + 1/(s + 1)\).

Specifying a rank array is meaningful only if you have in mind an external criterion of importance. If, as it usually happens, you do not have in mind a specific rank, the weighted \(\tau\) is defined by averaging the values
obtained using the decreasing lexicographical rank by \((x, y)\) and by \((y, x)\). This is the behavior with default parameters.

Note that if you are computing the weighted \(\tau\) on arrays of ranks, rather than of scores (i.e., a larger value implies a lower rank) you must negate the ranks, so that elements of higher rank are associated with a larger value.

**Parameters**

\(x, y\) : array_like
   Arrays of scores, of the same shape. If arrays are not 1-D, they will be flattened to 1-D.

**rank** : array_like of ints or bool, optional
   A nonnegative rank assigned to each element. If it is None, the decreasing lexicographical rank by \((x, y)\) will be used: elements of higher rank will be those with larger \(x\)-values, using \(y\)-values to break ties (in particular, swapping \(x\) and \(y\) will give a different result). If it is False, the element indices will be used directly as ranks. The default is True, in which case this function returns the average of the values obtained using the decreasing lexicographical rank by \((x, y)\) and by \((y, x)\).

**weigher** : callable, optional
   The weigher function. Must map nonnegative integers (zero representing the most important element) to a nonnegative weight. The default, None, provides hyperbolic weighing, that is, rank \(r\) is mapped to weight \(1/(r+1)\).

**additive** : bool, optional
   If True, the weight of an exchange is computed by adding the weights of the ranks of the exchanged elements; otherwise, the weights are multiplied. The default is True.

**Returns**

**correlation** : float
   The weighted \(\tau\) correlation index.

**pvalue** : float
   Presently \(\text{np.nan}\), as the null statistics is unknown (even in the additive hyperbolic case).

See also:

kendalltau Calculates Kendall’s tau.

spearmanr Calculates a Spearman rank-order correlation coefficient.

theilslopes Computes the Theil-Sen estimator for a set of points \((x, y)\).

**Notes**

This function uses an \(O(n \log n)\), mergesort-based algorithm [R712] that is a weighted extension of Knight’s algorithm for Kendall’s \(\tau\) [R713]. It can compute Shieh’s weighted \(\tau\) [R714] between rankings without ties (i.e., permutations) by setting *additive* and *rank* to False, as the definition given in [R712] is a generalization of Shieh’s.

NaNs are considered the smallest possible score.

New in version 0.19.0.

**References**

[R712], [R713], [R714]

**Examples**

```python
>>> from scipy import stats
>>> x = [12, 2, 1, 12, 2]
>>> y = [1, 4, 7, 1, 0]
```
NaNs are considered the smallest possible score:

```python
>>> x = [12, 2, 1, 12, 2]
>>> y = [1, 4, 7, 1, np.nan]
>>> tau, _ = stats.weightedtau(x, y)
>>> tau
-0.56694968153682723
```

This is exactly Kendall’s tau:

```python
>>> x = [12, 2, 1, 12, 2]
>>> y = [1, 4, 7, 1, 0]
>>> tau, _ = stats.weightedtau(x, y, weigher=lambda x: 1)
>>> tau
-0.47140452079103173
```

```python
>>> x = [12, 2, 1, 12, 2]
>>> y = [1, 4, 7, 1, 0]
>>> stats.weightedtau(x, y, rank=None)
WeightedTauResult(correlation=-0.4157652301037516, pvalue=nan)
>>> stats.weightedtau(y, x, rank=None)
WeightedTauResult(correlation=-0.71813413296990281, pvalue=nan)
```

**scipy.stats.linregress** *(x, y=None)*

Calculate a linear least-squares regression for two sets of measurements.

**Parameters**

- x, y : array_like
  
  Two sets of measurements. Both arrays should have the same length. If only x is given (and y=None), then it must be a two-dimensional array where one dimension has length 2. The two sets of measurements are then found by splitting the array along the length-2 dimension.

**Returns**

- slope : float
  
  slope of the regression line

- intercept : float
  
  intercept of the regression line

- rvalue : float
  
  correlation coefficient

- pvalue : float
  
  two-sided p-value for a hypothesis test whose null hypothesis is that the slope is zero, using Wald Test with t-distribution of the test statistic.

- stderr : float
  
  Standard error of the estimated gradient.

**See also:**

- scipy.optimize.curve_fit
  
  Use non-linear least squares to fit a function to data.

- scipy.optimize.leastsq
  
  Minimize the sum of squares of a set of equations.
Examples

```python
>>> import matplotlib.pyplot as plt
>>> from scipy import stats

>>> np.random.seed(12345678)

>>> x = np.random.random(10)

>>> y = np.random.random(10)

>>> slope, intercept, r_value, p_value, std_err = stats.linregress(x, y)

To get coefficient of determination (r_squared)

```python

```python
>>> print("r-squared:", r_value**2)

r-squared: 0.080402268539
```

Plot the data along with the fitted line

```python
>>> plt.plot(x, y, 'o', label='original data')

>>> plt.plot(x, intercept + slope*x, 'r', label='fitted line')

>>> plt.legend()

>>> plt.show()
```

```python

scipy.stats.theilslopes(y, x=None, alpha=0.95)

Computes the Theil-Sen estimator for a set of points (x, y).

theilslopes implements a method for robust linear regression. It computes the slope as the median of all slopes between paired values.

**Parameters**

- `y`: array_like
  Dependent variable.
- `x`: array_like or None, optional
  Independent variable. If None, use `arange(len(y))` instead.
- `alpha`: float, optional
  Confidence degree between 0 and 1. Default is 95% confidence. Note that `alpha` is symmetric around 0.5, i.e. both 0.1 and 0.9 are interpreted as “find the 90% confidence interval”.

**Returns**

- `medslope`: float
  Theil slope.
- `medintercept`: float
  Theil intercept.
The intercept of the Theil line, as \( \text{median}(y) - \text{medslope} \times \text{median}(x) \).

- **lo_slope**: float
  Lower bound of the confidence interval on medslope.

- **up_slope**: float
  Upper bound of the confidence interval on medslope.

**Notes**

The implementation of `theilslopes` follows [R700]. The intercept is not defined in [R700], and here it is defined as \( \text{median}(y) - \text{medslope} \times \text{median}(x) \), which is given in [R702]. Other definitions of the intercept exist in the literature. A confidence interval for the intercept is not given as this question is not addressed in [R700].

**References**

[R700], [R701], [R702]

**Examples**

```python
>>> from scipy import stats
>>> import matplotlib.pyplot as plt

>>> x = np.linspace(-5, 5, num=150)
>>> y = x + np.random.normal(size=x.size)
>>> y[11:15] += 10  # add outliers
>>> y[-5:] -= 7

Compute the slope, intercept and 90% confidence interval. For comparison, also compute the least-squares fit with `linregress`:

```python
>>> res = stats.theilslopes(y, x, 0.90)
>>> lsq_res = stats.linregress(x, y)
```

Plot the results. The Theil-Sen regression line is shown in red, with the dashed red lines illustrating the confidence interval of the slope (note that the dashed red lines are not the confidence interval of the regression as the confidence interval of the intercept is not included). The green line shows the least-squares fit for comparison.

```python
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, y, 'b. ')
>>> ax.plot(x, res[1] + res[0] * x, 'r- ')
>>> ax.plot(x, lsq_res[1] + lsq_res[0] * x, 'g- ')
>>> plt.show()
```

This is a two-sided test for the null hypothesis that the expected value (mean) of a sample of independent observations `a` is equal to the given population mean, `popmean`.

**Parameters**

- `a` : array_like
  - sample observation
- `popmean` : float or array_like

5.27. **Statistical functions** *(scipy.stats)* 2003
expected value in null hypothesis, if array_like than it must have the same
shape as a excluding the axis dimension

axis : int or None, optional
    Axis along which to compute test. If None, compute over the whole array a.
	nan_policy : {‘propagate’, ‘raise’, ‘omit’}, optional
    Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default is ‘propagate’.

Returns

statistic : float or array
    t-statistic

pvalue : float or array
    two-tailed p-value

Examples

>>> from scipy import stats

>>> np.random.seed(7654567)  # fix seed to get the same result
>>> rvs = stats.norm.rvs(loc=5, scale=10, size=(50,2))

Test if mean of random sample is equal to true mean, and different mean. We reject the null hypothesis in the second case and don’t reject it in the first case.

>>> stats.ttest_1samp(rvs,5.0)
(array([-0.68014479, -0.04323899]), array([ 0.49961383, 0.96568674]))

Examples using axis and non-scalar dimension for population mean.

>>> stats.ttest_1samp(rvs,[5.0,0.0])
(array([-0.68014479, 4.11038784]), array([ 0.00789095, 0.00014999]))

scipy.stats.ttest_ind(a, b, axis=0, equal_var=True, nan_policy='propagate')

Calculate the T-test for the means of two independent samples of scores.

This is a two-sided test for the null hypothesis that 2 independent samples have identical average (expected) values. This test assumes that the populations have identical variances by default.

Parameters

a, b : array_like
    The arrays must have the same shape, except in the dimension corresponding to axis (the first, by default).

axis : int or None, optional
    Axis along which to compute test. If None, compute over the whole arrays, a, and b.

equal_var : bool, optional
    If True (default), perform a standard independent 2 sample test that assumes equal population variances [R704]. If False, perform Welch’s t-test, which does not assume equal population variance [R705].

New in version 0.11.0.
**nan_policy** : {'propagate', 'raise', 'omit'}, optional
Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns**

- **statistic** : float or array
  The calculated t-statistic.
- **pvalue** : float or array
  The two-tailed p-value.

**Notes**

We can use this test, if we observe two independent samples from the same or different population, e.g. exam scores of boys and girls or of two ethnic groups. The test measures whether the average (expected) value differs significantly across samples. If we observe a large p-value, for example larger than 0.05 or 0.1, then we cannot reject the null hypothesis of identical average scores. If the p-value is smaller than the threshold, e.g. 1%, 5% or 10%, then we reject the null hypothesis of equal averages.

**References**

[R704], [R705]

**Examples**

```python
>>> from scipy import stats
>>> np.random.seed(12345678)

Test with sample with identical means:

```-```r```v```s```1``` = ```stats.norm.rvs(loc=5,scale=10,size=500)
```r```v```s```2``` = ```stats.norm.rvs(loc=5,scale=10,size=500)
```stats.ttest_ind(rvs1,rvs2)
(0.26833823296239279, 0.78849443369564776)
```stats.ttest_ind(rvs1,rvs2, equal_var = False)
(0.26833823296239279, 0.78849452749500748)
```ttest_ind``` underestimates p for unequal variances:

```-```r```v```s```3``` = ```stats.norm.rvs(loc=5, scale=20, size=500)
```stats.ttest_ind(rvs1, rvs3)
(-0.46580283298287162, 0.64145827413436174)
```stats.ttest_ind(rvs1, rvs3, equal_var = False)
(-0.46580283298287162, 0.64149646246569292)

When n1 != n2, the equal variance t-statistic is no longer equal to the unequal variance t-statistic:

```-```r```v```s```4``` = ```stats.norm.rvs(loc=5, scale=20, size=100)
```stats.ttest_ind(rvs1, rvs4)
(-0.99882539442782481, 0.3182832709103896)
```stats.ttest_ind(rvs1, rvs4, equal_var = False)
(-0.69712570584654099, 0.48716927725402048)

T-test with different means, variance, and n:

```-```r```v```s```5``` = ```stats.norm.rvs(loc=8, scale=20, size=100)
```stats.ttest_ind(rvs1, rvs5)
(-1.4679669854490653, 0.14263895620529152)
```stats.ttest_ind(rvs1, rvs5, equal_var = False)
(-0.94365973617132992, 0.34744170334794122)```
scipy.stats.ttest_ind_from_stats(mean1, std1, nobs1, mean2, std2, nobs2, equal_var=True)

T-test for means of two independent samples from descriptive statistics.

This is a two-sided test for the null hypothesis that two independent samples have identical average (expected) values.

**Parameters**

- **mean1**: array_like
  - The mean(s) of sample 1.
- **std1**: array_like
  - The standard deviation(s) of sample 1.
- **nobs1**: array_like
  - The number(s) of observations of sample 1.
- **mean2**: array_like
  - The mean(s) of sample 2
- **std2**: array_like
  - The standard deviation(s) of sample 2.
- **nobs2**: array_like
  - The number(s) of observations of sample 2.
- **equal_var**: bool, optional
  - If True (default), perform a standard independent 2 sample test that assumes equal population variances [R706]. If False, perform Welch’s t-test, which does not assume equal population variance [R707].

**Returns**

- **statistic**: float or array
  - The calculated t-statistics
- **pvalue**: float or array
  - The two-tailed p-value.

**See also:**

scipy.stats.ttest_ind

**Notes**

New in version 0.16.0.

**References**

[R706], [R707]

**Examples**

Suppose we have the summary data for two samples, as follows:

<table>
<thead>
<tr>
<th>Sample</th>
<th>Sample Size</th>
<th>Mean</th>
<th>Variance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sample 1</td>
<td>13</td>
<td>15.0</td>
<td>87.5</td>
</tr>
<tr>
<td>Sample 2</td>
<td>11</td>
<td>12.0</td>
<td>39.0</td>
</tr>
</tbody>
</table>

Apply the t-test to this data (with the assumption that the population variances are equal):

```python
>>> from scipy.stats import ttest_ind_from_stats
>>> ttest_ind_from_stats(mean1=15.0, std1=np.sqrt(87.5), nobs1=13,
...                        mean2=12.0, std2=np.sqrt(39.0), nobs2=11)
Ttest_indResult(statistic=0.90513580933102689, pvalue=0.37519967975814872)
```

For comparison, here is the data from which those summary statistics were taken. With this data, we can compute the same result using `scipy.stats.ttest_ind`:
scipy.stats.ttest_rel(a, b, axis=0, nan_policy='propagate')

Calculate the T-test on TWO RELATED samples of scores, a and b.

This is a two-sided test for the null hypothesis that 2 related or repeated samples have identical average (expected) values.

**Parameters**

- `a`, `b` : array_like
  - The arrays must have the same shape.
- `axis` : int or None, optional
  - Axis along which to compute test. If None, compute over the whole arrays, `a`, and `b`.
- `nan_policy` : {'propagate', 'raise', 'omit'}, optional
  - Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default is ‘propagate’.

**Returns**

- `statistic` : float or array
t-statistic
- `pvalue` : float or array
two-tailed p-value

**Notes**

Examples for the use are scores of the same set of student in different exams, or repeated sampling from the same units. The test measures whether the average score differs significantly across samples (e.g. exams). If we observe a large p-value, for example greater than 0.05 or 0.1 then we cannot reject the null hypothesis of identical average scores. If the p-value is smaller than the threshold, e.g. 1%, 5% or 10%, then we reject the null hypothesis of equal averages. Small p-values are associated with large t-statistics.

**References**

https://en.wikipedia.org/wiki/T-test#Dependent_t-test_for_paired_samples

**Examples**

```python
>>> from scipy import stats
>>> np.random.seed(12345678)  # fix random seed to get same numbers

>>> rvs1 = stats.norm.rvs(loc=5, scale=10, size=500)
>>> rvs2 = (stats.norm.rvs(loc=5, scale=10, size=500) +
...         stats.norm.rvs(scale=0.2, size=500))
>>> stats.ttest_rel(rvs1, rvs2)
(0.24101764965300962, 0.80964043445811562)

>>> rvs3 = (stats.norm.rvs(loc=8, scale=10, size=500) +
...         stats.norm.rvs(scale=0.2, size=500))
>>> stats.ttest_rel(rvs1, rvs3)
(-3.9995108708727933, 7.3082402191726459e-005)
```

scipy.stats.kstest(rvs, cdf, args=(), N=20, alternative='two-sided', mode='approx')

Perform the Kolmogorov-Smirnov test for goodness of fit.

This performs a test of the distribution G(x) of an observed random variable against a given distribution F(x). Under the null hypothesis the two distributions are identical, G(x)=F(x). The alternative hypothesis can be either
'two-sided' (default), 'less' or 'greater'. The KS test is only valid for continuous distributions.

**Parameters**

- **rvs**: str, array or callable
  If a string, it should be the name of a distribution in `scipy.stats`. If an array, it should be a 1-D array of observations of random variables. If a callable, it should be a function to generate random variables; it is required to have a keyword argument `size`.

- **cdf**: str or callable
  If a string, it should be the name of a distribution in `scipy.stats`. If `rvs` is a string then `cdf` can be False or the same as `rvs`. If a callable, that callable is used to calculate the cdf.

- **args**: tuple, sequence, optional
  Distribution parameters, used if `rvs` or `cdf` are strings.

- **N**: int, optional
  Sample size if `rvs` is string or callable. Default is 20.

- **alternative**: {'two-sided', 'less','greater'}, optional
  Defines the alternative hypothesis (see explanation above). Default is 'two-sided'.

- **mode**: 'approx' (default) or 'asymp', optional
  Defines the distribution used for calculating the p-value.
  - 'approx': use approximation to exact distribution of test statistic
  - 'asymp': use asymptotic distribution of test statistic

**Returns**

- **statistic**: float
  KS test statistic, either D, D+ or D-.

- **pvalue**: float
  One-tailed or two-tailed p-value.

**Notes**

In the one-sided test, the alternative is that the empirical cumulative distribution function of the random variable is “less” or “greater” than the cumulative distribution function F(x) of the hypothesis, G(x) <= F(x), resp. G(x) >= F(x).

**Examples**

```python
>>> from scipy import stats

>>> x = np.linspace(-15, 15, 9)
>>> stats.kstest(x, 'norm')
(0.44435602715924361, 0.038850142705171065)
```

```python
>>> np.random.seed(987654321)  # set random seed to get the same result
>>> stats.kstest('norm', False, N=100)
(0.058352892479417884, 0.88531190944151261)
```

The above lines are equivalent to:

```python
>>> np.random.seed(987654321)
>>> stats.kstest(stats.norm.rvs(size=100), 'norm')
(0.058352892479417884, 0.88531190944151261)
```

**Test against one-sided alternative hypothesis**

Shift distribution to larger values, so that $c_{dgp}(x) < norm.cdf(x)$:
>>> np.random.seed(987654321)
>>> x = stats.norm.rvs(loc=0.2, size=100)
>>> stats.kstest(x,'norm', alternative = 'less')
(0.1246329735846891, 0.04089164077641749)

Reject equal distribution against alternative hypothesis: less

>>> stats.kstest(x,'norm', alternative = 'greater')
(0.007211523321631108, 0.98531158590396394)

Don’t reject equal distribution against alternative hypothesis: greater

>>> stats.kstest(x,'norm', mode='asymp')
(0.1246329735846891, 0.08944488871182088)

Testing t distributed random variables against normal distribution

With 100 degrees of freedom the t distribution looks close to the normal distribution, and the K-S test does not reject the hypothesis that the sample came from the normal distribution:

>>> np.random.seed(987654321)
>>> stats.kstest(stats.t.rvs(100,size=100),'norm')
(0.072018929165471257, 0.67630062862479168)

With 3 degrees of freedom the t distribution looks sufficiently different from the normal distribution, that we can reject the hypothesis that the sample came from the normal distribution at the 10% level:

>>> np.random.seed(987654321)
>>> stats.kstest(stats.t.rvs(3,size=100),'norm')
(0.131016895759829, 0.05882622255312224)

scipy.stats.chisquare(f_obs,f_exp=None,ddof=0,axis=0)
Calculate a one-way chi square test.

The chi square test tests the null hypothesis that the categorical data has the given frequencies.

Parameters

- **f_obs**: array_like
  Observed frequencies in each category.

- **f_exp**: array_like, optional
  Expected frequencies in each category. By default the categories are assumed to be equally likely.

- **ddof**: int, optional
  “Delta degrees of freedom”: adjustment to the degrees of freedom for the p-value. The p-value is computed using a chi-squared distribution with \( k - 1 - \text{ddof} \) degrees of freedom, where \( k \) is the number of observed frequencies. The default value of ddof is 0.

- **axis**: int or None, optional
  The axis of the broadcast result of f_obs and f_exp along which to apply the test. If axis is None, all values in f_obs are treated as a single data set. Default is 0.

Returns

- **chisq**: float or ndarray
  The chi-squared test statistic. The value is a float if axis is None or f_obs and f_exp are 1-D.

- **p**: float or ndarray
  The p-value of the test. The value is a float if ddof and the return value chisq are scalars.
See also:

power_divergence, mstats.chisquare

Notes

This test is invalid when the observed or expected frequencies in each category are too small. A typical rule is that all of the observed and expected frequencies should be at least 5.

The default degrees of freedom, k-1, are for the case when no parameters of the distribution are estimated. If p parameters are estimated by efficient maximum likelihood then the correct degrees of freedom are k-1-p. If the parameters are estimated in a different way, then the dof can be between k-1-p and k-1. However, it is also possible that the asymptotic distribution is not a chisquare, in which case this test is not appropriate.

References

[R621], [R622]

Examples

When just $f_{obs}$ is given, it is assumed that the expected frequencies are uniform and given by the mean of the observed frequencies.

```python
>>> from scipy.stats import chisquare
>>> chisquare([16, 18, 16, 14, 12, 12])
(2.0, 0.84914503608460956)
```

With $f_{exp}$ the expected frequencies can be given.

```python
>>> chisquare([16, 18, 16, 14, 12, 12], f_exp=[16, 16, 16, 16, 16, 8])
(3.5, 0.62338762774958223)
```

When $f_{obs}$ is 2-D, by default the test is applied to each column.

```python
>>> obs = np.array([[[16, 18, 16, 14, 12, 12], [32, 24, 16, 28, 20, 24]]]).T
>>> obs.shape
(6, 2)
>>> chisquare(obs)
(array([ 2. , 6.66666667]), array([ 0.84914504, 0.24663415]))
```

By setting axis=None, the test is applied to all data in the array, which is equivalent to applying the test to the flattened array.

```python
>>> chisquare(obs, axis=None)
(23.31034482758621, 0.015975692534127565)
>>> chisquare(obs.ravel())
(23.31034482758621, 0.015975692534127565)
```

$ddof$ is the change to make to the default degrees of freedom.

```python
>>> chisquare([16, 18, 16, 14, 12, 12], ddof=1)
(2.0, 0.7357588823428467)
```

The calculation of the p-values is done by broadcasting the chi-squared statistic with $ddof$.

```python
>>> chisquare([16, 18, 16, 14, 12, 12], ddof=[0,1,2])
(2.0, array([ 0.84914504, 0.73575888, 0.5724067 ]))
```
\( f_{\text{obs}} \) and \( f_{\text{exp}} \) are also broadcast. In the following, \( f_{\text{obs}} \) has shape (6,) and \( f_{\text{exp}} \) has shape (2, 6), so the result of broadcasting \( f_{\text{obs}} \) and \( f_{\text{exp}} \) has shape (2, 6). To compute the desired chi-squared statistics, we use \( \text{axis}=1 \):

```python
>>> chisquare([16, 18, 16, 14, 12, 12],
              f_exp=[[16, 16, 16, 16, 16, 8], [8, 20, 20, 16, 12, 12]],
              axis=1)
(array([ 3.5 , 9.25]), array([ 0.62338763, 0.09949846]))
```

```
scipy.stats.power_divergence (f_obs, f_exp=None, ddof=0, axis=0, lambda_=None)
Cressie-Read power divergence statistic and goodness of fit test.

This function tests the null hypothesis that the categorical data has the given frequencies, using the Cressie-Read power divergence statistic.

Parameters

- \( f_{\text{obs}} \): array_like
  Observed frequencies in each category.
- \( f_{\text{exp}} \): array_like, optional
  Expected frequencies in each category. By default the categories are assumed to be equally likely.
- \( \text{ddof} \): int, optional
  “Delta degrees of freedom”: adjustment to the degrees of freedom for the p-value. The p-value is computed using a chi-squared distribution with \( k - 1 - \text{ddof} \) degrees of freedom, where \( k \) is the number of observed frequencies. The default value of \( \text{ddof} \) is 0.
- \( \text{axis} \): int or None, optional
  The axis of the broadcast result of \( f_{\text{obs}} \) and \( f_{\text{exp}} \) along which to apply the test. If \( \text{axis} \) is None, all values in \( f_{\text{obs}} \) are treated as a single data set. Default is 0.
- \( \text{lambda} \): float or str, optional
  \( \text{lambda} \) gives the power in the Cressie-Read power divergence statistic. The default is 1. For convenience, \( \text{lambda} \) may be assigned one of the following strings, in which case the corresponding numerical value is used:

<table>
<thead>
<tr>
<th>String</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;pearson&quot;</td>
<td>1</td>
<td>Pearson's chi-squared statistic.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>In this case, the function is equivalent to <code>stats.chisquare</code>.</td>
</tr>
<tr>
<td>&quot;log-likelihood&quot;</td>
<td>0</td>
<td>Log-likelihood ratio. Also known as the G-test [R684].</td>
</tr>
<tr>
<td>&quot;freeman-tukey&quot;</td>
<td>-1/2</td>
<td>Freeman-Tukey statistic.</td>
</tr>
<tr>
<td>&quot;mod-log-likelihood&quot;</td>
<td>-1</td>
<td>Modified log-likelihood ratio.</td>
</tr>
<tr>
<td>&quot;neyman&quot;</td>
<td>-2</td>
<td>Neyman's statistic.</td>
</tr>
<tr>
<td>&quot;cressie-read&quot;</td>
<td>2/3</td>
<td>The power recommended in [R686].</td>
</tr>
</tbody>
</table>

Returns

- \( \text{statistic} \): float or ndarray
  The Cressie-Read power divergence test statistic. The value is a float if \( \text{axis} \) is None or if \( f_{\text{obs}} \) and \( f_{\text{exp}} \) are 1-D.
- \( \text{pvalue} \): float or ndarray
  The p-value of the test. The value is a float if \( \text{ddof} \) and the return value \( \text{stat} \) are scalars.
See also:
chisquare

Notes
This test is invalid when the observed or expected frequencies in each category are too small. A typical rule is that all of the observed and expected frequencies should be at least 5.

When \( \lambda \) is less than zero, the formula for the statistic involves dividing by \( f_{\text{obs}} \), so a warning or error may be generated if any value in \( f_{\text{obs}} \) is 0.

Similarly, a warning or error may be generated if any value in \( f_{\text{exp}} \) is zero when \( \lambda \geq 0 \).

The default degrees of freedom, \( k-1 \), are for the case when no parameters of the distribution are estimated. If \( p \) parameters are estimated by efficient maximum likelihood then the correct degrees of freedom are \( k-1-p \). If the parameters are estimated in a different way, then the dof can be between \( k-1-p \) and \( k-1 \). However, it is also possible that the asymptotic distribution is not a chisquare, in which case this test is not appropriate.

This function handles masked arrays. If an element of \( f_{\text{obs}} \) or \( f_{\text{exp}} \) is masked, then data at that position is ignored, and does not count towards the size of the data set.

New in version 0.13.0.

References
[R682], [R683], [R684], [R685], [R686]

Examples
(See chisquare for more examples.)

When just \( f_{\text{obs}} \) is given, it is assumed that the expected frequencies are uniform and given by the mean of the observed frequencies. Here we perform a G-test (i.e. use the log-likelihood ratio statistic):

```python
>>> from scipy.stats import power_divergence
>>> power_divergence([16, 18, 16, 14, 12, 12], lambda_='log-likelihood')
(2.006573162632538, 0.84823476779463769)
```

The expected frequencies can be given with the \( f_{\text{exp}} \) argument:

```python
>>> power_divergence([16, 18, 16, 14, 12, 12],
...                  f_exp=[16, 16, 16, 16, 16, 8],
...                  lambda_='log-likelihood')
(3.3281031031031033, 0.6495419288047497)
```

When \( f_{\text{obs}} \) is 2-D, by default the test is applied to each column.

```python
>>> obs = np.array([[[16, 18, 16, 14, 12, 12], [32, 24, 16, 28, 20, 24]]]).T
>>> obs.shape
(6, 2)
>>> power_divergence(obs, lambda_="log-likelihood")
(array([ 2.00657316,  6.77634498]), array([ 0.84823477,  0.23781225]))
```

By setting \( \text{axis=None} \), the test is applied to all data in the array, which is equivalent to applying the test to the flattened array.

```python
>>> power_divergence(obs, axis=None)
(23.31034482758621, 0.015975692534127565)
>>> power_divergence(obs.ravel())
(23.31034482758621, 0.015975692534127565)
```
**ddof** is the change to make to the default degrees of freedom.

```python
>>> power_divergence([16, 18, 16, 14, 12, 12], ddof=1)
(2.0, 0.73575888234288467)
```

The calculation of the p-values is done by broadcasting the test statistic with **ddof**.

```python
>>> power_divergence([16, 18, 16, 14, 12, 12], ddof=[0,1,2])
(2.0, array([0.84914504, 0.73575888, 0.5724067]))
```

**f_obs** and **f_exp** are also broadcast. In the following, **f_obs** has shape (6,) and **f_exp** has shape (2, 6), so the result of broadcasting **f_obs** and **f_exp** has shape (2, 6). To compute the desired chi-squared statistics, we must use **axis=1**:

```python
>>> power_divergence([16, 18, 16, 14, 12, 12],
...                   axis=1)
(array([3.5, 9.25]), array([0.62338763, 0.09949846]))
```

`scipy.stats.ks_2samp(data1, data2)`

Compute the Kolmogorov-Smirnov statistic on 2 samples.

This is a two-sided test for the null hypothesis that 2 independent samples are drawn from the same continuous distribution.

**Parameters**
- **data1, data2** : sequence of 1-D ndarrays

  two arrays of sample observations assumed to be drawn from a continuous distribution, sample sizes can be different

**Returns**
- **statistic** : float

  KS statistic

- **pvalue** : float

  two-tailed p-value

**Notes**

This tests whether 2 samples are drawn from the same distribution. Note that, like in the case of the one-sample K-S test, the distribution is assumed to be continuous.

This is the two-sided test, one-sided tests are not implemented. The test uses the two-sided asymptotic Kolmogorov-Smirnov distribution.

If the K-S statistic is small or the p-value is high, then we cannot reject the hypothesis that the distributions of the two samples are the same.

**Examples**

```python
>>> from scipy import stats

>>> np.random.seed(12345678)  # fix random seed to get the same result

>>> n1 = 200  # size of first sample

>>> n2 = 300  # size of second sample

For a different distribution, we can reject the null hypothesis since the pvalue is below 1%:

```python
>>> rvsl = stats.norm.rvs(size=n1, loc=0., scale=1)

>>> rvss = stats.norm.rvs(size=n2, loc=0.5, scale=1.5)

>>> stats.ks_2samp(rvsl, rvss)
(0.20833333333333337, 4.6674975515806989e-005)
```
For a slightly different distribution, we cannot reject the null hypothesis at a 10% or lower alpha since the p-value at 0.144 is higher than 10%:

```python
>>> rvs3 = stats.norm.rvs(size=n2, loc=0.01, scale=1.0)
>>> stats.ks_2samp(rvs1, rvs3)
(0.10333333333333333, 0.14498781825751686)
```

For an identical distribution, we cannot reject the null hypothesis since the p-value is high, 41%:

```python
>>> rvs4 = stats.norm.rvs(size=n2, loc=0.0, scale=1.0)
>>> stats.ks_2samp(rvs1, rvs4)
(0.0799999999999996, 0.41126949729859719)
```

```python
scipy.stats.mannwhitneyu(x, y, use_continuity=True, alternative=None)
```
Compute the Mann-Whitney rank test on samples x and y.

**Parameters**
- `x, y`: array_like
  Array of samples, should be one-dimensional.
- `use_continuity`: bool, optional
  Whether a continuity correction (1/2.) should be taken into account. Default is True.
- `alternative`: None (deprecated), 'less', 'two-sided', or 'greater'
  Whether to get the p-value for the one-sided hypothesis ('less' or 'greater') or for the two-sided hypothesis ('two-sided'). Defaults to None, which results in a p-value half the size of the 'two-sided' p-value and a different U statistic. The default behavior is not the same as using 'less' or 'greater': it only exists for backward compatibility and is deprecated.

**Returns**
- `statistic`: float
  The Mann-Whitney U statistic, equal to min(U for x, U for y) if alternative is equal to None (deprecated; exists for backward compatibility), and U for y otherwise.
- `pvalue`: float
  p-value assuming an asymptotic normal distribution. One-sided or two-sided, depending on the choice of alternative.

**Notes**
Use only when the number of observation in each sample is > 20 and you have 2 independent samples of ranks. Mann-Whitney U is significant if the u-obtained is LESS THAN or equal to the critical value of U.

This test corrects for ties and by default uses a continuity correction.

**References**
[R665], [R666]

```python
scipy.stats.tiecorrect(rankvals)
```
Tie correction factor for ties in the Mann-Whitney U and Kruskal-Wallis H tests.

**Parameters**
- `rankvals`: array_like
  A 1-D sequence of ranks. Typically this will be the array returned by `stats.rankdata`.

**Returns**
- `factor`: float
  Correction factor for U or H.

**See also:**
- `rankdata` Assign ranks to the data
- `mannwhitneyu` Mann-Whitney rank test
**kruskal**  
Kruskal-Wallis H test

**References**

[R703]

**Examples**

```python
>>> from scipy.stats import tiecorrect, rankdata
>>> tiecorrect([1, 2.5, 2.5, 4])
0.9
>>> ranks = rankdata([1, 3, 2, 4, 5, 7, 2, 8, 4])
>>> ranks
array([ 1. , 4. , 2.5, 5.5, 7. , 8. , 2.5, 9. , 5.5])
>>> tiecorrect(ranks)
0.9833333333333333
```
scipy.stats.ranksums(x, y)
Compute the Wilcoxon rank-sum statistic for two samples.

The Wilcoxon rank-sum test tests the null hypothesis that two sets of measurements are drawn from the same
distribution. The alternative hypothesis is that values in one sample are more likely to be larger than the values
in the other sample.

This test should be used to compare two samples from continuous distributions. It does not handle ties be-
tween measurements in x and y. For tie-handling and an optional continuity correction see scipy.stats.
mannwhitneyu.

Parameters
- x, y : array_like
  The data from the two samples

Returns
- statistic : float
  The test statistic under the large-sample approximation that the rank sum
  statistic is normally distributed
- pvalue : float
  The two-sided p-value of the test

References
[R691]
s scipy.stats.wilcoxon(x, y=None, zero_method='wilcox', correction=False)
Calculate the Wilcoxon signed-rank test.

The Wilcoxon signed-rank test tests the null hypothesis that two related paired samples come from the same
distribution. In particular, it tests whether the distribution of the differences x - y is symmetric about zero. It is
a non-parametric version of the paired T-test.

Parameters
- x : array_like
  The first set of measurements.
- y : array_like, optional
  The second set of measurements. If y is not given, then the x array is con-
sidered to be the differences between the two sets of measurements.
- zero_method : string, {"pratt", "wilcox", "zsplit"}, optional
  "pratt": Pratt treatment: includes zero-differences in the ranking pro-
  cess (more conservative)
  "wilcox": Wilcox treatment: discards all zero-differences
  "zsplit": Zero rank split: just like Pratt, but splitting the zero rank be-
  tween positive and negative ones
- correction : bool, optional
  If True, apply continuity correction by adjusting the Wilcoxon rank statistic
  by 0.5 towards the mean value when computing the z-statistic. Default is
  False.

Returns
- statistic : float
  The sum of the ranks of the differences above or below zero, whichever is
  smaller.
- pvalue : float
  The two-sided p-value for the test.

Notes
Because the normal approximation is used for the calculations, the samples used should be large. A typical rule
is to require that n > 20.

References
[R715]
scipy.stats.kruskal(*args, **kwargs)
Compute the Kruskal-Wallis H-test for independent samples

The Kruskal-Wallis H-test tests the null hypothesis that the population median of all of the groups are equal. It is a non-parametric version of ANOVA. The test works on 2 or more independent samples, which may have different sizes. Note that rejecting the null hypothesis does not indicate which of the groups differs. Post-hoc comparisons between groups are required to determine which groups are different.

Parameters

sample1, sample2, ... : array_like
Two or more arrays with the sample measurements can be given as arguments.

nan_policy : {'propagate', 'raise', 'omit'}, optional
Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default is ‘propagate’.

Returns

statistic : float
The Kruskal-Wallis H statistic, corrected for ties

pvalue : float
The p-value for the test using the assumption that H has a chi square distribution

See also:
f_oneway 1-way ANOVA
mannwhitneyu
Mann-Whitney rank test on two samples.
friedmanchisquare
Friedman test for repeated measurements

Notes

Due to the assumption that H has a chi square distribution, the number of samples in each group must not be too small. A typical rule is that each sample must have at least 5 measurements.

References

[R658], [R659]

Examples

```python
>>> from scipy import stats
>>> x = [1, 3, 5, 7, 9]
>>> y = [2, 4, 6, 8, 10]
>>> stats.kruskal(x, y)
KruskalResult(statistic=0.27272727272727337, pvalue=0.60150813444058948)
>>> x = [1, 1, 1]
>>> y = [2, 2, 2]
>>> z = [2, 2]
>>> stats.kruskal(x, y, z)
KruskalResult(statistic=7.0, pvalue=0.030197383422318501)
```

scipy.stats.friedmanchisquare(*args)
Compute the Friedman test for repeated measurements

The Friedman test tests the null hypothesis that repeated measurements of the same individuals have the same distribution. It is often used to test for consistency among measurements obtained in different ways. For example, if two measurement techniques are used on the same set of individuals, the Friedman test can be used to determine if the two measurement techniques are consistent.
Parameters

measurements1, measurements2, measurements3... : array_like

Arrays of measurements. All of the arrays must have the same number of elements. At least 3 sets of measurements must be given.

Returns

statistic : float

the test statistic, correcting for ties

pvalue : float

the associated p-value assuming that the test statistic has a chi squared distribution

Notes

Due to the assumption that the test statistic has a chi squared distribution, the p-value is only reliable for n > 10 and more than 6 repeated measurements.

References

[R641]

scipy.stats.combine_pvalues(pvalues, method='fisher', weights=None)

Methods for combining the p-values of independent tests bearing upon the same hypothesis.

Parameters

pvalues : array_like, 1-D

Array of p-values assumed to come from independent tests.

method : {'fisher', 'stouffer'}, optional

Name of method to use to combine p-values. The following methods are available:

•"fisher”: Fisher’s method (Fisher’s combined probability test), the default.
•"stouffer”: Stouffer’s Z-score method.

weights : array_like, 1-D, optional

Optional array of weights used only for Stouffer’s Z-score method.

Returns

statistic: float

The statistic calculated by the specified method: - “fisher”: The chi-squared statistic - “stouffer”: The Z-score

pval: float

The combined p-value.

Notes

Fisher’s method (also known as Fisher’s combined probability test) [R623] uses a chi-squared statistic to compute a combined p-value. The closely related Stouffer’s Z-score method [R624] uses Z-scores rather than p-values. The advantage of Stouffer’s method is that it is straightforward to introduce weights, which can make Stouffer’s method more powerful than Fisher’s method when the p-values are from studies of different size [R625] [R626].

Fisher’s method may be extended to combine p-values from dependent tests [R627]. Extensions such as Brown’s method and Kost’s method are not currently implemented.

New in version 0.15.0.

[R623], [R624], [R625], [R626], [R627]

scipy.stats.jarque_bera(x)

Perform the Jarque-Bera goodness of fit test on sample data.

The Jarque-Bera test tests whether the sample data has the skewness and kurtosis matching a normal distribution.

Note that this test only works for a large enough number of data samples (>2000) as the test statistic asymptotically has a Chi-squared distribution with 2 degrees of freedom.
**Parameters**  
x : array_like

**Returns**  
jb_value : float  
The test statistic.
p : float  
The p-value for the hypothesis test.

**References**

[R653]

**Examples**

```python
>>> from scipy import stats
>>> np.random.seed(987654321)
>>> x = np.random.normal(0, 1, 100000)
>>> y = np.random.rayleigh(1, 100000)
>>> stats.jarque_bera(x)
(4.7165707989581342, 0.09458225503041906)
>>> stats.jarque_bera(y)
(6713.7098481434222, 0.0)
```

```
ansari(x, y)  
Perform the Ansari-Bradley test for equal scale parameters

bartlett(*args)  
Perform Bartlett’s test for equal variances

levene(*args, **kwds)  
Perform Levene test for equal variances.

shapiro(x)  
Perform the Shapiro-Wilk test for normality.

anderson(x[, dist])  
Anderson-Darling test for data coming from a particular distribution

anderson_ksamp(samples[, midrank])  
The Anderson-Darling test for k-samples.

binom_test(x[, n, p, alternative])  
Perform a test that the probability of success is p.

fligner(*args, **kwds)  
Perform Fligner-Killeen test for equality of variance.

median_test(*args, **kwds)  
Mood’s median test.

mood(x, y[, axis])  
Perform Mood’s test for equal scale parameters.
```

scipy.stats.ansari(x, y)  
Perform the Ansari-Bradley test for equal scale parameters

The Ansari-Bradley test is a non-parametric test for the equality of the scale parameter of the distributions from which two samples were drawn.

**Parameters**  
x, y : array_like

**Returns**  
statistic : float  
The Ansari-Bradley test statistic
pvalue : float  
The p-value of the hypothesis test

**See also:**

fligner  
A non-parametric test for the equality of k variances

mood  
A non-parametric test for the equality of two scale parameters

**Notes**

The p-value given is exact when the sample sizes are both less than 55 and there are no ties, otherwise a normal approximation for the p-value is used.
References

[R608]

scipy.stats.bartlett(*args)

Perform Bartlett’s test for equal variances

Bartlett’s test tests the null hypothesis that all input samples are from populations with equal variances. For samples from significantly non-normal populations, Levene’s test levene is more robust.

Parameters

sample1, sample2, ... : array_like

arrays of sample data. May be different lengths.

Returns

statistic : float

The test statistic.

pvalue : float

The p-value of the test.

See also:

fligner A non-parametric test for the equality of k variances
levene A robust parametric test for equality of k variances

Notes

Conover et al. (1981) examine many of the existing parametric and nonparametric tests by extensive simulations and they conclude that the tests proposed by Fligner and Killeen (1976) and Levene (1960) appear to be superior in terms of robustness of departures from normality and power [R612].

References

[R610], [R611], [R612], [R613]

scipy.stats.levene(*args, **kwds)

Perform Levene test for equal variances.

The Levene test tests the null hypothesis that all input samples are from populations with equal variances. Levene’s test is an alternative to Bartlett’s test bartlett in the case where there are significant deviations from normality.

Parameters

sample1, sample2, ... : array_like

The sample data, possibly with different lengths

center : {'mean', 'median', 'trimmed'}, optional

Which function of the data to use in the test. The default is ‘median’.

proportiontocut : float, optional

When center is ‘trimmed’, this gives the proportion of data points to cut from each end. (See scipy.stats.trim_mean.) Default is 0.05.

Returns

statistic : float

The test statistic.

pvalue : float

The p-value for the test.

Notes

Three variations of Levene’s test are possible. The possibilities and their recommended usages are:

* ‘median’ : Recommended for skewed (non-normal) distributions
* ‘mean’ : Recommended for symmetric, moderate-tailed distributions.
* ‘trimmed’ : Recommended for heavy-tailed distributions.
References

[R662], [R663], [R664]

scipy.stats.shapiro(x)
Perform the Shapiro-Wilk test for normality.

The Shapiro-Wilk test tests the null hypothesis that the data was drawn from a normal distribution.

Parameters

- x : array_like
  Array of sample data.

Returns

- W : float
  The test statistic.

- p-value : float
  The p-value for the hypothesis test.

See also:

anderson
The Anderson-Darling test for normality

kstest
The Kolmogorov-Smirnov test for goodness of fit.

Notes

The algorithm used is described in [R695] but censoring parameters as described are not implemented. For N > 5000 the W test statistic is accurate but the p-value may not be.

The chance of rejecting the null hypothesis when it is true is close to 5% regardless of sample size.

References

[R692], [R693], [R694], [R695]

Examples

```python
>>> from scipy import stats
>>> np.random.seed(12345678)
>>> x = stats.norm.rvs(loc=5, scale=3, size=100)
>>> stats.shapiro(x)
(0.9772805571556091, 0.08144091814756393)
```

scipy.stats.anderson(x, dist='norm')
Anderson-Darling test for data coming from a particular distribution

The Anderson-Darling test is a modification of the Kolmogorov-Smirnov test kstest for the null hypothesis that a sample is drawn from a population that follows a particular distribution. For the Anderson-Darling test, the critical values depend on which distribution is being tested against. This function works for normal, exponential, logistic, or Gumbel (Extreme Value Type I) distributions.

Parameters

- x : array_like
  array of sample data

- dist : {'norm', 'expon', 'logistic', 'gumbel', 'gumbel_l', 'gumbel_r', 'extreme1'}, optional the type of distribution to test against. The default is 'norm' and 'extreme1', 'gumbel_l' and 'gumbel' are synonyms.

Returns

- statistic : float
  The Anderson-Darling test statistic

- critical_values : list
  The critical values for this distribution

- significance_level : list
  The significance levels for the corresponding critical values in percents.
  The function returns critical values for a differing set of significance levels depending on the distribution that is being tested against.
Critical values provided are for the following significance levels:

- **normal/exponential**
  - 15%, 10%, 5%, 2.5%, 1%
- **logistic**
  - 25%, 10%, 5%, 2.5%, 1%, 0.5%
- **Gumbel**
  - 25%, 10%, 5%, 2.5%, 1%

If $A_2$ is larger than these critical values then for the corresponding significance level, the null hypothesis that the data come from the chosen distribution can be rejected.

### References

[R601], [R602], [R603], [R604], [R605], [R606]

#### `scipy.stats.anderson_ksamp` *(samples, midrank=True)*

The Anderson-Darling test for k-samples.

The k-sample Anderson-Darling test is a modification of the one-sample Anderson-Darling test. It tests the null hypothesis that k-samples are drawn from the same population without having to specify the distribution function of that population. The critical values depend on the number of samples.

#### Parameters

- `samples`: sequence of 1-D array_like
  - Array of sample data in arrays.
- `midrank`: bool, optional
  - Type of Anderson-Darling test which is computed. Default (True) is the midrank test applicable to continuous and discrete populations. If False, the right side empirical distribution is used.

#### Returns

- `statistic`: float
  - Normalized k-sample Anderson-Darling test statistic.
- `critical_values`: array
  - The critical values for significance levels 25%, 10%, 5%, 2.5%, 1%.
- `significance_level`: float
  - An approximate significance level at which the null hypothesis for the provided samples can be rejected.

#### Raises

- `ValueError`
  - If less than 2 samples are provided, a sample is empty, or no distinct observations are in the samples.

#### See also:

- `ks_2samp` 2 sample Kolmogorov-Smirnov test
- `anderson` 1 sample Anderson-Darling test

### Notes

[R607] Defines three versions of the k-sample Anderson-Darling test: one for continuous distributions and two for discrete distributions, in which ties between samples may occur. The default of this routine is to compute the version based on the midrank empirical distribution function. This test is applicable to continuous and discrete data. If midrank is set to False, the right side empirical distribution is used for a test for discrete data. According to [R607], the two discrete test statistics differ only slightly if a few collisions due to round-off errors occur in the test not adjusted for ties between samples.

New in version 0.14.0.

### References

[R607]
Examples

```python
>>> from scipy import stats
>>> np.random.seed(314159)

The null hypothesis that the two random samples come from the same distribution can be rejected at the 5% level because the returned test value is greater than the critical value for 5% (1.961) but not at the 2.5% level. The interpolation gives an approximate significance level of 3.1%:

```python
>>> stats.anderson_ksamp([np.random.normal(size=50), ...
... np.random.normal(loc=0.5, size=30)])
```

(2.4615796189876105,
 array([ 0.325,  1.226,  1.961,  2.718,  3.752]),
 0.03134990135800783)
```

The null hypothesis cannot be rejected for three samples from an identical distribution. The approximate p-value (87%) has to be computed by extrapolation and may not be very accurate:

```python
>>> stats.anderson_ksamp([np.random.normal(size=50), ...
... np.random.normal(size=30), np.random.normal(size=20)])
```

(-0.73091722665244196,
 array([ 0.44925884,  1.3052767 ,  1.9434184 ,  2.57696569,  3.41634856]),
 0.8789283903979661)
```

scipy.stats.binom_test(x, n=None, p=0.5, alternative='two-sided')
Perform a test that the probability of success is p.

This is an exact, two-sided test of the null hypothesis that the probability of success in a Bernoulli experiment is p.

**Parameters**
- x: integer or array_like
  - the number of successes, or if x has length 2, it is the number of successes and the number of failures.
- n: integer
  - the number of trials. This is ignored if x gives both the number of successes and failures
- p: float, optional
  - The hypothesized probability of success. 0 <= p <= 1. The default value is p = 0.5
- alternative: {'two-sided', 'greater', 'less'}, optional
  - Indicates the alternative hypothesis. The default value is ‘two-sided’.

**Returns**
- p-value: float
  - The p-value of the hypothesis test

**References**
[R614]

scipy.stats.fligner(*args, **kwds)
Perform Fligner-Killeen test for equality of variance.

Fligner’s test tests the null hypothesis that all input samples are from populations with equal variances. Fligner-Killeen’s test is distribution free when populations are identical [R638].

**Parameters**
- sample1, sample2, ...: array_like
  - Arrays of sample data. Need not be the same length.
- center: {'mean', 'median', 'trimmed'}, optional
  - Keyword argument controlling which function of the data is used in computing the test statistic. The default is ‘median’.
proportiontocut : float, optional
    When center is ‘trimmed’, this gives the proportion of data points to cut
    from each end. (See scipy.stats.trim_mean.) Default is 0.05.

Returns

statistic : float
    The test statistic.

pvalue : float
    The p-value for the hypothesis test.

See also:

bartlett A parametric test for equality of k variances in normal samples
levene A robust parametric test for equality of k variances

Notes

As with Levene’s test there are three variants of Fligner’s test that differ by the measure of central tendency used
in the test. See levene for more information.

Conover et al. (1981) examine many of the existing parametric and nonparametric tests by extensive simulations
and they conclude that the tests proposed by Fligner and Killeen (1976) and Levene (1960) appear to be superior
in terms of robustness of departures from normality and power [R639].

References

[R637], [R638], [R639], [R640]

scipy.stats.median_test(*args, **kwds)
Mood’s median test.

Test that two or more samples come from populations with the same median.

Let \( n = \text{len(args)} \) be the number of samples. The “grand median” of all the data is computed, and a con-
tingency table is formed by classifying the values in each sample as being above or below the grand median. The
contingency table, along with \( \text{correction} \) and \( \text{lambda}_\_\), are passed to scipy.stats.chi2_contingency
to compute the test statistic and p-value.

Parameters sample1, sample2, ... : array_like
    The set of samples. There must be at least two samples. Each sample must
    be a one-dimensional sequence containing at least one value. The samples
    are not required to have the same length.

ties : str, optional
    Determines how values equal to the grand median are classified in the con-
tingency table. The string must be one of:

    "below":
        Values equal to the grand median are counted as
        \( \equiv \text{"below"} \).
    "above":
        Values equal to the grand median are counted as
        \( \equiv \text{"above"} \).
    "ignore":
        Values equal to the grand median are \textbf{not} counted.

The default is “below”.

correction : bool, optional
    If True, and there are just two samples, apply Yates’ correction for continu-
ity when computing the test statistic associated with the contingency table.
    Default is True.

lambda_ : float or str, optional.
By default, the statistic computed in this test is Pearson’s chi-squared statistic. `lambda_` allows a statistic from the Cressie-Read power divergence family to be used instead. See `power_divergence` for details. Default is 1 (Pearson’s chi-squared statistic).

**nan_policy** : {'propagate', 'raise', 'omit'}, optional

Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default is ‘propagate’.

**Returns**

stat : float

The test statistic. The statistic that is returned is determined by `lambda_`. The default is Pearson’s chi-squared statistic.

p : float

The p-value of the test.

m : float

The grand median.

table : ndarray

The contingency table. The shape of the table is (2, n), where n is the number of samples. The first row holds the counts of the values above the grand median, and the second row holds the counts of the values below the grand median. The table allows further analysis with, for example, `scipy.stats.chi2_contingency`, or with `scipy.stats.fisher_exact` if there are two samples, without having to recompute the table. If `nan_policy` is “propagate” and there are nans in the input, the return value for `table` is `None`.

See also:

**kruskal**

Compute the Kruskal-Wallis H-test for independent samples.

**mannwhitneyu**

Computes the Mann-Whitney rank test on samples x and y.

Notes

New in version 0.15.0.

Examples

A biologist runs an experiment in which there are three groups of plants. Group 1 has 16 plants, group 2 has 15 plants, and group 3 has 17 plants. Each plant produces a number of seeds. The seed counts for each group are:

<table>
<thead>
<tr>
<th>Group 1</th>
<th>Group 2</th>
<th>Group 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>10, 14, 14, 18, 20, 22, 24, 25, 31, 31, 32, 39, 43, 48, 49</td>
<td>28, 30, 31, 33, 34, 35, 36, 40, 44, 55, 57, 61, 91, 92, 99</td>
<td>0, 3, 9, 22, 23, 25, 25, 33, 34, 34, 40, 45, 46, 48, 62, 67, 84</td>
</tr>
</tbody>
</table>

The following code applies Mood’s median test to these samples.

```python
>>> g1 = [10, 14, 14, 18, 20, 22, 24, 25, 31, 31, 32, 39, 43, 43, 48, 49]
>>> g2 = [28, 30, 31, 33, 34, 35, 36, 40, 44, 55, 57, 61, 91, 92, 99]
>>> g3 = [0, 3, 9, 22, 23, 25, 25, 33, 34, 34, 40, 45, 46, 48, 62, 67, 84]
>>> from scipy.stats import median_test
>>> stat, p, med, tbl = median_test(g1, g2, g3)
```

The median is
and the contingency table is

```
>>> tbl
array([[ 5, 10,  7],
       [11, 5, 10]])
```

\(p\) is too large to conclude that the medians are not the same:

```
>>> p
0.12609082774093244
```

The “G-test” can be performed by passing `lambda_="log-likelihood"` to `median_test`.

```
>>> g, p, med, tbl = median_test(g1, g2, g3, lambda_="log-likelihood")
>>> p
0.1224779737117837
```

The median occurs several times in the data, so we’ll get a different result if, for example, `ties="above"` is used:

```
>>> stat, p, med, tbl = median_test(g1, g2, g3, ties="above")
>>> p
0.063873276069553273
```

```
>>> tbl
array([[ 5, 11,  9],
       [11, 4,  8]])
```

This example demonstrates that if the data set is not large and there are values equal to the median, the \(p\)-value can be sensitive to the choice of `ties`.

```
scipy.stats.mood(x, y, axis=0)
```

Perform Mood’s test for equal scale parameters.

Mood’s two-sample test for scale parameters is a non-parametric test for the null hypothesis that two samples are drawn from the same distribution with the same scale parameter.

- **Parameters**
  - `x, y`: array_like
    - Arrays of sample data.
  - `axis`: int, optional
    - The axis along which the samples are tested. \(x\) and \(y\) can be of different length along \(axis\). If `axis` is None, \(x\) and \(y\) are flattened and the test is done on all values in the flattened arrays.

- **Returns**
  - `z`: scalar or ndarray
    - The z-score for the hypothesis test. For 1-D inputs a scalar is returned.
  - `p-value`: scalar ndarray
    - The \(p\)-value for the hypothesis test.

See also:

- `fligner` A non-parametric test for the equality of k variances
- `ansari` A non-parametric test for the equality of 2 variances
- `bartlett` A parametric test for equality of k variances in normal samples
- `levene` A parametric test for equality of k variances
Notes

The data are assumed to be drawn from probability distributions \( f(x) \) and \( f(x/s) / s \) respectively, for some probability density function \( f \). The null hypothesis is that \( s == 1 \).

For multi-dimensional arrays, if the inputs are of shapes \( (n0, n1, n2, n3) \) and \( (n0, m1, n2, n3) \), then if \( axis=1 \), the resulting \( z \) and \( p \) values will have shape \( (n0, n2, n3) \). Note that \( n1 \) and \( m1 \) don’t have to be equal, but the other dimensions do.

Examples

```python
>>> from scipy import stats
>>> np.random.seed(1234)
>>> x2 = np.random.randn(2, 45, 6, 7)
>>> x1 = np.random.randn(2, 30, 6, 7)
>>> z, p = stats.mood(x1, x2, axis=1)
>>> p.shape
(2, 6, 7)
```

Find the number of points where the difference in scale is not significant:

```python
>>> (p > 0.1).sum()
74
```

Perform the test with different scales:

```python
>>> x1 = np.random.randn(2, 30)
>>> x2 = np.random.randn(2, 35) * 10.0
>>> stats.mood(x1, x2, axis=1)
(array([-5.7178125 , -5.25342163]), array([ 1.07904114e-08, 1.49299218e-07]))
```

\[ \text{boxcox}(x[, \text{lmbda}, \text{alpha}]) \]

Return a positive dataset transformed by a Box-Cox power transformation.

\[ \text{boxcox\_normmax}(x[, \text{brack}, \text{method}]) \]

Compute optimal Box-Cox transform parameter for input data.

\[ \text{boxcox\_llf}(\text{lmb}, \text{data}) \]

The boxcox log-likelihood function.

\[ \text{entropy}(\text{pk}[, \text{qk}, \text{base}]) \]

Calculate the entropy of a distribution for given probability values.

\[ \text{scipy.stats.boxcox}(x, \text{lmbda}=\text{None}, \text{alpha}=\text{None}) \]

Return a positive dataset transformed by a Box-Cox power transformation.

**Parameters**

- \( x \): ndarray
  - Input array. Should be 1-dimensional.
  - \text{lmbda} : {None, scalar}, optional
    - If \text{lmbda} is not None, do the transformation for that value.
    - If \text{lmbda} is None, find the lambda that maximizes the log-likelihood function and return it as the second output argument.
  - \text{alpha} : {None, float}, optional
    - If \text{alpha} is not None, return the \( 100 * (1-\text{alpha})\% \) confidence interval for \text{lmbda} as the third output argument. Must be between 0.0 and 1.0.

**Returns**

- \text{boxcox} : ndarray
  - Box-Cox power transformed array.
- \text{maxlog} : float, optional
  - If the \text{lmbda} parameter is None, the second returned argument is the lambda that maximizes the log-likelihood function.
(min_ci, max_ci) : tuple of float, optional
If lmbda parameter is None and alpha is not None, this returned tuple
of floats represents the minimum and maximum confidence limits given
alpha.

See also:
probplot, boxcox_normplot, boxcox_normmax, boxcox_llf

Notes
The Box-Cox transform is given by:

*y* = \(\frac{(x^{\lambda} - 1)}{\lambda}\),  \(\text{for } \lambda > 0\)

\(\log(x)\),  \(\text{for } \lambda = 0\)

boxcox requires the input data to be positive. Sometimes a Box-Cox transformation provides a shift parameter
to achieve this; boxcox does not. Such a shift parameter is equivalent to adding a positive constant to *x* before
calling boxcox.

The confidence limits returned when alpha is provided give the interval where:

\[ llf(\hat{\lambda}) - llf(\lambda) < \frac{1}{2} \chi^2(1 - \alpha, 1), \]

with \(llf\) the log-likelihood function and \(\chi^2\) the chi-squared function.

References
211-252 (1964).

Examples

```python
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

We generate some random variates from a non-normal distribution and make a probability plot for it, to show it
is non-normal in the tails:

```python
>>> fig = plt.figure()
>>> ax1 = fig.add_subplot(211)
>>> x = stats.loggamma.rvs(5, size=500) + 5
>>> prob = stats.probplot(x, dist=stats.norm, plot=ax1)
>>> ax1.set_xlabel('')
>>> ax1.set_title('Probplot against normal distribution')
```

We now use boxcox to transform the data so it’s closest to normal:

```python
>>> ax2 = fig.add_subplot(212)
>>> xt, _ = stats.boxcox(x)
>>> prob = stats.probplot(xt, dist=stats.norm, plot=ax2)
>>> ax2.set_title('Probplot after Box-Cox transformation')
```

```python
>>> plt.show()
```
Theoretical quantiles

Ordered Values
Probplot against normal distribution

Ordered Values
Probplot after Box-Cox transformation

scipy.stats.boxcox_normmax (x, brack=(-2.0, 2.0), method='pearsonr')
Compute optimal Box-Cox transform parameter for input data.

Parameters
x : array_like
   Input array.
brack : 2-tuple, optional
   The starting interval for a downhill bracket search with optimize.brent. Note
   that this is in most cases not critical; the final result is allowed to be outside
   this bracket.
method : str, optional
   The method to determine the optimal transform parameter (boxcox
   lmbda parameter). Options are:
   ‘pearsonr’ (default)
   Maximizes the Pearson correlation coefficient between y =
   boxcox(x) and the expected values for y if x would be
   normally-distributed.
   ‘mle’
   Minimizes the log-likelihood boxcox_1lf. This is the
   method used in boxcox.
   ‘all’
   Use all optimization methods available, and return all re-
   sults. Useful to compare different methods.

Returns
maxlog : float or ndarray
   The optimal transform parameter found. An array instead of a scalar for
   method='all'.

See also:
boxcox, boxcox_1lf, boxcox_normplot

Examples

```python
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> np.random.seed(1234)  # make this example reproducible

Generate some data and determine optimal lmbda in various ways:

```
```python
>>> lmax_mle
7.177...
>>> lmax_pearsonr
7.916...
>>> stats.boxcox_normmax(x, method='all')
array([ 7.91667384, 7.17718692])

>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> prob = stats.boxcox_normplot(x, -10, 10, plot=ax)
>>> ax.axvline(lmax_mle, color='r')
>>> ax.axvline(lmax_pearsonr, color='g', ls='--')

>>> plt.show()
```

```
scipy.stats.boxcox_llf(lmb, data)
The boxcox log-likelihood function.

Parameters:
- lmb: scalar
  Parameter for Box-Cox transformation. See boxcox for details.
- data: array_like
  Data to calculate Box-Cox log-likelihood for. If data is multi-dimensional,
  the log-likelihood is calculated along the first axis.

Returns:
- llf: float or ndarray
  Box-Cox log-likelihood of data given lmb. A float for 1-D data, an array
  otherwise.

See also:
boxcox, probplot, boxcox_normplot, boxcox_normmax

Notes
The Box-Cox log-likelihood function is defined here as

\[ llf = (\lambda - 1) \sum_i (\log(x_i)) - N/2 \log(\sum_i (y_i - \bar{y})^2/N), \]

where y is the Box-Cox transformed input data x.
```
Examples

```python
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> from mpl_toolkits.axes_grid1.inset_locator import inset_axes

>>> np.random.seed(1245)
Generate some random variates and calculate Box-Cox log-likelihood values for them for a range of \( \lambda \) values:

```python
>>> x = stats.loggamma.rvs(5, loc=10, size=1000)
>>> lmbdas = np.linspace(-2, 10)
>>> llf = np.zeros(lmbdas.shape, dtype=float)
>>> for ii, lmbda in enumerate(lmbdas):
...    llf[ii] = stats.boxcox_llf(lmbda, x)
Also find the optimal \( \lambda \) value with `boxcox`:

```python
>>> x_most_normal, lmbda_optimal = stats.boxcox(x)
Plot the log-likelihood as function of \( \lambda \). Add the optimal \( \lambda \) as a horizontal line to check that that's really the optimum:

```python
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(lmbdas, llf, 'b.-')
>>> ax.axhline(stats.boxcox_llf(lmbda_optimal, x), color='r')
>>> ax.set_xlabel('\( \lambda \) parameter')
>>> ax.set_ylabel('Box-Cox log-likelihood')
Now add some probability plots to show that where the log-likelihood is maximized the data transformed with `boxcox` looks closest to normal:

```python
>>> locs = [3, 10, 4]  # 'lower left', 'center', 'lower right'
>>> for lmbda, loc in zip([-1, lmbda_optimal, 9], locs):
...    xt = stats.boxcox(x, lmbda=lmbda)
...    (osm, osr), (slope, intercept, r_sq) = stats.probplot(xt)
...    ax_inset = inset_axes(ax, width="20\%", height="20\%")
...    ax_inset.plot(osm, osr, 'c.', osm, slope*osm + intercept, 'k-')
...    ax_inset.set_xticklabels([])
...    ax_inset.set_yticklabels([])
...    ax_inset.set_title('${\lambda=%.2f}$' % lmbda)

```python
>>> plt.show()
```
scipy.stats.entropy(pk, qk=None, base=None)
Calculate the entropy of a distribution for given probability values.

If only probabilities \( pk \) are given, the entropy is calculated as \( S = -\sum(pk \times \log(pk)), \text{ axis}=0 \).

If \( qk \) is not None, then compute the Kullback-Leibler divergence \( S = \sum(pk \times \log(pk / qk)), \text{ axis}=0 \).

This routine will normalize \( pk \) and \( qk \) if they don’t sum to 1.

Parameters

- \( pk \) : sequence
  Defines the (discrete) distribution. \( pk[i] \) is the (possibly unnormalized) probability of event \( i \).

- \( qk \) : sequence, optional
  Sequence against which the relative entropy is computed. Should be in the same format as \( pk \).

- \( base \) : float, optional
  The logarithmic base to use, defaults to \( e \) (natural logarithm).

Returns

- \( S \) : float
  The calculated entropy.

wasserstein_distance(u_values, v_values[, ...])
Compute the first Wasserstein distance between two 1D distributions.

energy_distance(u_values, v_values[, ...])
Compute the energy distance between two 1D distributions.

scipy.stats.wasserstein_distance(u_values, v_values, u_weights=None, v_weights=None)
Compute the first Wasserstein distance between two 1D distributions.

This distance is also known as the earth mover’s distance, since it can be seen as the minimum amount of “work” required to transform \( u \) into \( v \), where “work” is measured as the amount of distribution weight that must be moved, multiplied by the distance it has to be moved.

New in version 1.0.0.

Parameters

- \( u_values, v_values \) : array_like
  Values observed in the (empirical) distribution.

- \( u_weights, v_weights \) : array_like, optional
  Weight for each value. If unspecified, each value is assigned the same weight. \( u_weights \) (resp. \( v_weights \)) must have the same length as \( u_values \).
(resp. v_values). If the weight sum differs from 1, it must still be positive and finite so that the weights can be normalized to sum to 1.

**Returns**

`distance`: float

The computed distance between the distributions.

**Notes**

The first Wasserstein distance between the distributions \( u \) and \( v \) is:

\[
\ell_1(u, v) = \inf_{\pi \in \Gamma(u, v)} \int_{\mathbb{R} \times \mathbb{R}} |x - y| d\pi(x, y)
\]

where \( \Gamma(u, v) \) is the set of (probability) distributions on \( \mathbb{R} \times \mathbb{R} \) whose marginals are \( u \) and \( v \) on the first and second factors respectively.

If \( U \) and \( V \) are the respective CDFs of \( u \) and \( v \), this distance also equals to:

\[
\ell_1(u, v) = \int_{-\infty}^{+\infty} |U - V|
\]

See [R711] for a proof of the equivalence of both definitions.

The input distributions can be empirical, therefore coming from samples whose values are effectively inputs of the function, or they can be seen as generalized functions, in which case they are weighted sums of Dirac delta functions located at the specified values.

**References**

[R710], [R711]

**Examples**

```python
>>> from scipy.stats import wasserstein_distance
>>> wasserstein_distance([0, 1, 3], [5, 6, 8])
5.0
>>> wasserstein_distance([0, 1], [0, 1], [3, 1], [2, 2])
0.25
>>> wasserstein_distance([3.4, 3.9, 7.5, 7.8], [4.5, 1.4], ... [1.4, 0.9, 3.1, 7.2], [3.2, 3.5])
4.0781331438047861
```

**scipy.stats.energy_distance** *(u_values, v_values, u_weights=None, v_weights=None)*

Compute the energy distance between two 1D distributions.

New in version 1.0.0.

**Parameters**

- **u_values, v_values**: array_like
  Values observed in the (empirical) distribution.

- **u_weights, v_weights**: array_like, optional
  Weight for each value. If unspecified, each value is assigned the same weight. \( u_weights \) (resp. \( v_weights \)) must have the same length as \( u_values \) (resp. \( v_values \)). If the weight sum differs from 1, it must still be positive and finite so that the weights can be normalized to sum to 1.

**Returns**

`distance`: float

The computed distance between the distributions.

**Notes**

The energy distance between two distributions \( u \) and \( v \), whose respective CDFs are \( U \) and \( V \), equals to:

\[
D(u, v) = (2\mathbb{E}|X - Y| - \mathbb{E}|X - X'| - \mathbb{E}|Y - Y'|)^{1/2}
\]
where $X$ and $X'$ (resp. $Y$ and $Y'$) are independent random variables whose probability distribution is $u$ (resp. $v$).

As shown in [R630], for one-dimensional real-valued variables, the energy distance is linked to the non-distribution-free version of the Cramer-von Mises distance:

$$D(u, v) = \sqrt{2l_2(u, v)} = \left(2\int_{-\infty}^{+\infty} (U - V)^2\right)^{1/2}$$

Note that the common Cramer-von Mises criterion uses the distribution-free version of the distance. See [R630] (section 2), for more details about both versions of the distance.

The input distributions can be empirical, therefore coming from samples whose values are effectively inputs of the function, or they can be seen as generalized functions, in which case they are weighted sums of Dirac delta functions located at the specified values.

### 5.27.5 Circular statistical functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>circmean(samples[, high, low, axis])</code></td>
<td>Compute the circular mean for samples in a range.</td>
</tr>
<tr>
<td><code>circvar(samples[, high, low, axis])</code></td>
<td>Compute the circular variance for samples assumed to be in a range.</td>
</tr>
<tr>
<td><code>circstd(samples[, high, low, axis])</code></td>
<td>Compute the circular standard deviation for samples assumed to be in the range [low to high].</td>
</tr>
</tbody>
</table>

**scipy.stats.circmean**(samples, high=6.283185307179586, low=0, axis=None)

Compute the circular mean for samples in a range.

**Parameters**

- **samples**: array_like
  Input array.
- **high**: float or int, optional
  High boundary for circular mean range. Default is $2 \times \pi$.
- **low**: float or int, optional
  Low boundary for circular mean range. Default is 0.
- **axis**: int, optional
  Axis along which means are computed. The default is to compute the mean of the flattened array.

**Returns**

- **circmean**: float
  Circular mean.
Examples

```python
>>> from scipy.stats import circmean
>>> circmean([0.1, 2*np.pi+0.2, 6*np.pi+0.3])
0.2
```

```python
>>> from scipy.stats import circmean
>>> circmean([0.2, 1.4, 2.6], high = 1, low = 0)
0.4
```

```python
scipy.stats.circvar(samples, high=6.283185307179586, low=0, axis=None)
```

Compute the circular variance for samples assumed to be in a range

**Parameters**

- `samples`: array_like
  Input array.
- `low`: float or int, optional
  Low boundary for circular variance range. Default is 0.
- `high`: float or int, optional
  High boundary for circular variance range. Default is `2*pi`.
- `axis`: int, optional
  Axis along which variances are computed. The default is to compute the variance of the flattened array.

**Returns**

- `circvar`: float
  Circular variance.

**Notes**

This uses a definition of circular variance that in the limit of small angles returns a number close to the ‘linear’ variance.

Examples

```python
>>> from scipy.stats import circvar
>>> circvar([0, 2*np.pi/3, 5*np.pi/3])
2.19722457734
```

```python
scipy.stats.circstd(samples, high=6.283185307179586, low=0, axis=None)
```

Compute the circular standard deviation for samples assumed to be in the range [low to high].

**Parameters**

- `samples`: array_like
  Input array.
- `low`: float or int, optional
  Low boundary for circular standard deviation range. Default is 0.
- `high`: float or int, optional
  High boundary for circular standard deviation range. Default is `2*pi`.
- `axis`: int, optional
  Axis along which standard deviations are computed. The default is to compute the standard deviation of the flattened array.

**Returns**

- `circstd`: float
  Circular standard deviation.

**Notes**

This uses a definition of circular standard deviation that in the limit of small angles returns a number close to the ‘linear’ standard deviation.
Examples

```python
>>> from scipy.stats import circstd
>>> circstd([0, 0.1*np.pi/2, 0.001*np.pi, 0.03*np.pi/2])
0.063564063306
```

## 5.27.6 Contingency table functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>chi2_contingency</code></td>
<td>Chi-square test of independence of variables in a contingency table.</td>
</tr>
<tr>
<td><code>contingency.expected_freq</code></td>
<td>Compute the expected frequencies from a contingency table.</td>

<tr>
<td><code>fisher_exact</code></td>
<td>Performs a Fisher exact test on a 2x2 contingency table.</td>
</tr>
</tbody>
</table>

### scipy.stats.chi2_contingency (observed, correction=True, lambda_=None)

Chi-square test of independence of variables in a contingency table.

This function computes the chi-square statistic and p-value for the hypothesis test of independence of the observed frequencies in the contingency table [R618] observed. The expected frequencies are computed based on the marginal sums under the assumption of independence; see scipy.stats.contingency.expected_freq. The number of degrees of freedom is (expressed using numpy functions and attributes):

```
dof = observed.size - sum(observed.shape) + observed.ndim - 1
```

**Parameters**

- **observed**: array_like
  The contingency table. The table contains the observed frequencies (i.e. number of occurrences) in each category. In the two-dimensional case, the table is often described as an “R x C table”.

- **correction**: bool, optional
  If True, and the degrees of freedom is 1, apply Yates’ correction for continuity. The effect of the correction is to adjust each observed value by 0.5 towards the corresponding expected value.

- **lambda_**: float or str, optional.
  By default, the statistic computed in this test is Pearson’s chi-squared statistic [R619]. lambda_ allows a statistic from the Cressie-Read power divergence family [R620] to be used instead. See power_divergence for details.

**Returns**

- **chi2**: float
  The test statistic.

- **p**: float
  The p-value of the test.

- **dof**: int
  Degrees of freedom.

- **expected**: ndarray, same shape as observed
  The expected frequencies, based on the marginal sums of the table.

**See also:**

- contingency.expected_freq, fisher_exact, chisquare, power_divergence
Notes

An often quoted guideline for the validity of this calculation is that the test should be used only if the observed and expected frequency in each cell is at least 5.

This is a test for the independence of different categories of a population. The test is only meaningful when the dimension of observed is two or more. Applying the test to a one-dimensional table will always result in expected equal to observed and a chi-square statistic equal to 0.

This function does not handle masked arrays, because the calculation does not make sense with missing values.

Like stats.chisquare, this function computes a chi-square statistic; the convenience this function provides is to figure out the expected frequencies and degrees of freedom from the given contingency table. If these were already known, and if the Yates’ correction was not required, one could use stats.chisquare. That is, if one calls:

```
chi2, p, dof, ex = chi2_contingency(obs, correction=False)
```

then the following is true:

```
(chi2, p) == stats.chisquare(obs.ravel(), f_exp=ex.ravel(),
                           ddof=obs.size - 1 - dof)
```

The lambda_ argument was added in version 0.13.0 of scipy.

References

[R618], [R619], [R620]

Examples

A two-way example (2 x 3):

```
>>> from scipy.stats import chi2_contingency
>>> obs = np.array([[10, 10, 20],
                  [20, 20, 20]])
>>> chi2_contingency(obs)
(2.7777777777777777, 0.24935220877729619, 2, array([[ 12., 12., 16.],
            [ 18., 18., 24.]]))
```

Perform the test using the log-likelihood ratio (i.e. the “G-test”) instead of Pearson’s chi-squared statistic.

```
>>> g, p, dof, expected = chi2_contingency(obs, lambda_="log-likelihood")
>>> g, p
(2.7688587616781319, 0.25046668010954165)
```

A four-way example (2 x 2 x 2 x 2):

```
>>> obs = np.array([[[12, 17],
                   [11, 16]],
                   [[11, 12],
                    [15, 16]],
                   [[23, 15],
                    [30, 22]],
                   [[14, 17],
                    [15, 16]]])
>>> chi2_contingency(obs)
(8.7584514426741897, 0.25046668010954165)
```
scipy.stats.contingency.expected_freq(observed)
Compute the expected frequencies from a contingency table.

Given an n-dimensional contingency table of observed frequencies, compute the expected frequencies for the table based on the marginal sums under the assumption that the groups associated with each dimension are independent.

Parameters

observed : array_like
    The table of observed frequencies. (While this function can handle a 1-D array, that case is trivial. Generally observed is at least 2-D.)

Returns

expected : ndarray of float64
    The expected frequencies, based on the marginal sums of the table. Same shape as observed.

Examples

```python
>>> observed = np.array([[10, 10, 20], [20, 20, 20]])
>>> from scipy.stats import expected_freq
>>> expected_freq(observed)
array([[ 12., 12., 16.],
       [ 18., 18., 24.]]
```

scipy.stats.contingency.margins(a)
Return a list of the marginal sums of the array a.

Parameters

a : ndarray
    The array for which to compute the marginal sums.

Returns

margsums : list of ndarrays
    A list of length a.ndim. margsums[k] is the result of summing a over all axes except k; it has the same number of dimensions as a, but the length of each axis except axis k will be 1.

Examples

```python
>>> a = np.arange(12).reshape(2, 6)
>>> a
array([[ 0,  1,  2,  3,  4,  5],
       [ 6,  7,  8,  9, 10, 11]])
>>> m0, m1 = margins(a)
>>> m0
array([[15],
       [51]])
```

```python
>>> b = np.arange(24).reshape(2,3,4)
>>> m0, m1, m2 = margins(b)
```
```python
>>> m0
array([[  66],
       [210]])
>>> m1
array([[  60],
       [  92],
       [124]])
>>> m2
array([[60, 66, 72, 78]])
```

```python
scipy.stats.fisher_exact(table, alternative='two-sided')
```

Performs a Fisher exact test on a 2x2 contingency table.

**Parameters**
- `table`: array_like of ints
  A 2x2 contingency table. Elements should be non-negative integers.
- `alternative`: {'two-sided', 'less', 'greater'}, optional
  Which alternative hypothesis to the null hypothesis the test uses. Default is 'two-sided'.

**Returns**
- `oddsratio`: float
  This is prior odds ratio and not a posterior estimate.
- `p_value`: float
  P-value, the probability of obtaining a distribution at least as extreme as the one that was actually observed, assuming that the null hypothesis is true.

**See also:**
- `chi2_contingency`
  Chi-square test of independence of variables in a contingency table.

**Notes**
The calculated odds ratio is different from the one R uses. This scipy implementation returns the (more common) “unconditional Maximum Likelihood Estimate”, while R uses the “conditional Maximum Likelihood Estimate”.

For tables with large numbers, the (inexact) chi-square test implemented in the function `chi2_contingency` can also be used.

**Examples**
Say we spend a few days counting whales and sharks in the Atlantic and Indian oceans. In the Atlantic ocean we find 8 whales and 1 shark, in the Indian ocean 2 whales and 5 sharks. Then our contingency table is:

<table>
<thead>
<tr>
<th></th>
<th>Atlantic</th>
<th>Indian</th>
</tr>
</thead>
<tbody>
<tr>
<td>whales</td>
<td>8</td>
<td>2</td>
</tr>
<tr>
<td>sharks</td>
<td>1</td>
<td>5</td>
</tr>
</tbody>
</table>

We use this table to find the p-value:

```python
>>> import scipy.stats as stats
>>> oddsratio, pvalue = stats.fisher_exact([[8, 2], [1, 5]])
>>> pvalue
0.0349...
```

The probability that we would observe this or an even more imbalanced ratio by chance is about 3.5%. A commonly used significance level is 5%—if we adopt that, we can therefore conclude that our observed imbalance is statistically significant; whales prefer the Atlantic while sharks prefer the Indian ocean.
5.27.7 Plot-tests

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ppcc_max(x[, brack, dist])</code></td>
<td>Calculate the shape parameter that maximizes the PPCC</td>
</tr>
<tr>
<td><code>ppcc_plot(x, a, b[, dist, plot, N])</code></td>
<td>Calculate and optionally plot probability plot correlation coefficient.</td>
</tr>
<tr>
<td><code>probplot(x[, sparams, dist, fit, plot, rvalue])</code></td>

<td>Compute parameters for a Box-Cox normality plot, optionally show it.</td>
</tr>
</tbody>
</table>

**scipy.stats.ppcc_max(x, brack=(0.0, 1.0), dist='tukeylambda')**

Calculate the shape parameter that maximizes the PPCC

The probability plot correlation coefficient (PPCC) plot can be used to determine the optimal shape parameter for a one-parameter family of distributions. `ppcc_max` returns the shape parameter that would maximize the probability plot correlation coefficient for the given data to a one-parameter family of distributions.

**Parameters**

- `x`: array_like
  Input array.
- `brack`: tuple, optional
  Triple (a,b,c) where (a<b<c). If bracket consists of two numbers (a, c) then they are assumed to be a starting interval for a downhill bracket search (see `scipy.optimize.brent`).
- `dist`: str or stats.distributions instance, optional
  Distribution or distribution function name. Objects that look enough like a stats.distributions instance (i.e. they have a `ppf` method) are also accepted. The default is `'tukeylambda'`.

**Returns**

- `shape_value`: float
  The shape parameter at which the probability plot correlation coefficient reaches its max value.

**See also:**

`ppcc_plot, probplot, boxcox`

**Notes**

The brack keyword serves as a starting point which is useful in corner cases. One can use a plot to obtain a rough visual estimate of the location for the maximum to start the search near it.

**References**

[R687], [R688]

**Examples**

First we generate some random data from a Tukey-Lambda distribution, with shape parameter -0.7:

```python
>>> from scipy import stats
>>> x = stats.tukeylambda.rvs(-0.7, loc=2, scale=0.5, size=10000,
...    random_state=1234567) + 1e4
```

Now we explore this data with a PPCC plot as well as the related probability plot and Box-Cox normplot. A red line is drawn where we expect the PPCC value to be maximal (at the shape parameter -0.7 used above):

```python
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure(figsize=(8, 6))
```
We calculate the value where the shape should reach its maximum and a red line is drawn there. The line should coincide with the highest point in the ppcc_plot.

```python
>>> max = stats.ppcc_max(x)
>>> ax.vlines(max, 0, 1, colors='r', label='Expected shape value')

>>> plt.show()
```

```
>> ax = fig.add_subplot(111)
res = stats.ppcc_plot(x, -5, 5, plot=ax)

spipy.stats.ppcc_plot (x, a, b, dist='tukeylambda', plot=None, N=80)
```

Calculate and optionally plot probability plot correlation coefficient.

The probability plot correlation coefficient (PPCC) plot can be used to determine the optimal shape parameter for a one-parameter family of distributions. It cannot be used for distributions without shape parameters (like the normal distribution) or with multiple shape parameters.

By default a Tukey-Lambda distribution (stats.tukeylambda) is used. A Tukey-Lambda PPCC plot interpolates from long-tailed to short-tailed distributions via an approximately normal one, and is therefore particularly useful in practice.

**Parameters**

- `x`: array_like
  Input array.
- `a, b`: scalar
  Lower and upper bounds of the shape parameter to use.
- `dist`: str or stats.distributions instance, optional
Distribution or distribution function name. Objects that look enough like a
stats.distributions instance (i.e. they have a ppf method) are also accepted.
The default is 'tukeylambda'.

plot : object, optional
If given, plots PPCC against the shape parameter. plot is an object that has
to have methods “plot” and “text”. The matplotlib.pyplot module
or a Matplotlib Axes object can be used, or a custom object with the same
methods. Default is None, which means that no plot is created.

N : int, optional
Number of points on the horizontal axis (equally distributed from a to b).

Returns
svals : ndarray
The shape values for which ppcc was calculated.

ppcc : ndarray
The calculated probability plot correlation coefficient values.

See also:
ppcc_max, probplot, boxcox_normplot, tukeylambda

References

Examples
First we generate some random data from a Tukey-Lambda distribution, with shape parameter -0.7:

```python
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> np.random.seed(1234567)
>>> x = stats.tukeylambda.rvs(-0.7, loc=2, scale=0.5, size=10000) + 1e4
```

Now we explore this data with a PPCC plot as well as the related probability plot and Box-Cox normplot. A red
line is drawn where we expect the PPCC value to be maximal (at the shape parameter -0.7 used above):

```python
>>> fig = plt.figure(figsize=(12, 4))
>>> ax1 = fig.add_subplot(131)
>>> ax2 = fig.add_subplot(132)
>>> ax3 = fig.add_subplot(133)
>>> res = stats.probplot(x, plot=ax1)
>>> res = stats.boxcox_normplot(x, -5, 5, plot=ax2)
>>> res = stats.ppcc_plot(x, -5, 5, plot=ax3)
>>> ax3.vlines(-0.7, 0, 1, colors='r', label='Expected shape value')
>>> plt.show()
```
scipy.stats.probplot(x, sparams=(), dist='norm', fit=True, plot=None, rvalue=False)

Calculate quantiles for a probability plot, and optionally show the plot.

Generates a probability plot of sample data against the quantiles of a specified theoretical distribution (the normal distribution by default). probplot optionally calculates a best-fit line for the data and plots the results using Matplotlib or a given plot function.

**Parameters**
- **x**: array_like
  Sample/response data from which probplot creates the plot.
- **sparams**: tuple, optional
  Distribution-specific shape parameters (shape parameters plus location and scale).
- **dist**: str or stats.distributions instance, optional
  Distribution or distribution function name. The default is ‘norm’ for a normal probability plot. Objects that look enough like a stats.distributions instance (i.e. they have a ppf method) are also accepted.
- **fit**: bool, optional
  Fit a least-squares regression (best-fit) line to the sample data if True (default).
- **plot**: object, optional
  If given, plots the quantiles and least squares fit. plot is an object that has to have methods “plot” and “text”. The matplotlib.pyplot module or a Matplotlib Axes object can be used, or a custom object with the same methods. Default is None, which means that no plot is created.

**Returns**
- **(osm, osr)**: tuple of ndarrays
  Tuple of theoretical quantiles (osm, order statistic medians) and ordered responses (osr). osr is simply sorted input x. For details on how osm is calculated see the Notes section.
- **(slope, intercept, r)**: tuple of floats, optional
  Tuple containing the result of the least-squares fit, if that is performed by probplot. r is the square root of the coefficient of determination. If fit=False and plot=None, this tuple is not returned.

**Notes**

Even if plot is given, the figure is not shown or saved by probplot: plt.show() or plt.savefig('figname.png') should be used after calling probplot.

probplot generates a probability plot, which should not be confused with a Q-Q or a P-P plot. Statsmodels has more extensive functionality of this type, see statsmodels.api.ProbPlot.

The formula used for the theoretical quantiles (horizontal axis of the probability plot) is Filliben’s estimate:

```plaintext
quantiles = dist.ppf(val), for

0.5**(1/n), for i = n
val = (i - 0.3175) / (n + 0.365), for i = 2, ..., n-1
1 - 0.5**(1/n), for i = 1
```

where i indicates the i-th ordered value and n is the total number of values.

**Examples**

```python
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> nsample = 100
>>> np.random.seed(7654321)
```
A t distribution with small degrees of freedom:
```python
>>> ax1 = plt.subplot(221)
>>> x = stats.t.rvs(3, size=nsample)
>>> res = stats.probplot(x, plot=plt)
```

A t distribution with larger degrees of freedom:
```python
>>> ax2 = plt.subplot(222)
>>> x = stats.t.rvs(25, size=nsample)
>>> res = stats.probplot(x, plot=plt)
```

A mixture of two normal distributions with broadcasting:
```python
>>> ax3 = plt.subplot(223)
>>> x = stats.norm.rvs(loc=[0,5], scale=[1,1.5],
...                     size=(nsample//2,2)).ravel()
>>> res = stats.probplot(x, plot=plt)
```

A standard normal distribution:
```python
>>> ax4 = plt.subplot(224)
>>> x = stats.norm.rvs(loc=0, scale=1, size=nsample)
>>> res = stats.probplot(x, plot=plt)
```

Produce a new figure with a loggamma distribution, using the `dist` and `sparams` keywords:
```python
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> x = stats.loggamma.rvs(c=2.5, size=500)
>>> res = stats.probplot(x, dist=stats.loggamma, sparams=(2.5,), plot=ax)
>>> ax.set_title("Probplot for loggamma dist with shape parameter 2.5")
```

Show the results with Matplotlib:
```python
>>> plt.show()
```
scipy.stats.boxcox_normplot(x, la, lb, plot=None, N=80)

Compute parameters for a Box-Cox normality plot, optionally show it.

A Box-Cox normality plot shows graphically what the best transformation parameter is to use in boxcox to obtain a distribution that is close to normal.

Parameters

- **x**: array_like
  Input array.

- **la, lb**: scalar
  The lower and upper bounds for the lambda values to pass to boxcox for Box-Cox transformations. These are also the limits of the horizontal axis of the plot if that is generated.

- **plot**: object, optional
  If given, plots the quantiles and least squares fit. plot is an object that has to have methods “plot” and “text”. The matplotlib.pyplot module or a Matplotlib Axes object can be used, or a custom object with the same methods. Default is None, which means that no plot is created.

- **N**: int, optional
  Number of points on the horizontal axis (equally distributed from la to lb).

Returns

- **lmbdas**: ndarray
  The lambda values for which a Box-Cox transform was done.

- **ppcc**: ndarray
  Probability Plot Correlation Coefficient, as obtained from probplot when fitting the Box-Cox transformed input x against a normal distribution.

See also:

- probplot, boxcox, boxcox_normmax, boxcox_llf, ppcc_max

Notes

Even if plot is given, the figure is not shown or saved by boxcox_normplot; plt.show() or plt.savefig('figname.png') should be used after calling probplot.

Examples

```python
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```
Generate some non-normally distributed data, and create a Box-Cox plot:

```python
>>> x = stats.loggamma.rvs(5, size=500) + 5
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> prob = stats.boxcox_normplot(x, -20, 20, plot=ax)
```

Determine and plot the optimal \( \lambda \) to transform \( x \) and plot it in the same plot:

```python
>>> _, maxlog = stats.boxcox(x)
>>> ax.axvline(maxlog, color='r')
```

```python
>>> plt.show()
```

5.27.8 Masked statistics functions

**Statistical functions for masked arrays** *(scipy.stats.mstats)*

This module contains a large number of statistical functions that can be used with masked arrays.

Most of these functions are similar to those in scipy.stats but might have small differences in the API or in the algorithm used. Since this is a relatively new package, some API changes are still possible.

`scipy.stats.mstats.argstoarray(*args)`

Constructs a 2D array from a group of sequences.

Sequences are filled with missing values to match the length of the longest sequence.
Parameters

\texttt{args} : sequences

Returns

\texttt{argstoarray} : MaskedArray

A \((m \times n)\) masked array, where \(m\) is the number of arguments and \(n\) the length of the longest argument.

Notes

\texttt{numpy.ma.row_stack} has identical behavior, but is called with a sequence of sequences.

\texttt{scipy.stats.mstats.chisquare} \((f\_obs, f\_exp=None, ddof=0, axis=0)\)

Calculate a one-way chi square test.

The chi square test tests the null hypothesis that the categorical data has the given frequencies.

Parameters

\texttt{f\_obs} : array_like

Observed frequencies in each category.

\texttt{f\_exp} : array_like, optional

Expected frequencies in each category. By default the categories are assumed to be equally likely.

\texttt{ddof} : int, optional

“Delta degrees of freedom”: adjustment to the degrees of freedom for the \(p\)-value. The \(p\)-value is computed using a chi-squared distribution with \(k - 1 - ddof\) degrees of freedom, where \(k\) is the number of observed frequencies. The default value of \(ddof\) is 0.

\texttt{axis} : int or None, optional

The axis of the broadcast result of \(f\_obs\) and \(f\_exp\) along which to apply the test. If \(axis\) is None, all values in \(f\_obs\) are treated as a single data set. Default is 0.

Returns

\texttt{chisq} : float or ndarray

The \(\chi^2\) test statistic. The value is a float if \(axis\) is None or \(f\_obs\) and \(f\_exp\) are 1-D.

\texttt{p} : float or ndarray

The \(p\)-value of the test. The value is a float if \(ddof\) and the return value \(chisq\) are scalars.

See also:

\texttt{power_divergence, mstats.chisquare}

Notes

This test is invalid when the observed or expected frequencies in each category are too small. A typical rule is that all of the observed and expected frequencies should be at least 5.

The default degrees of freedom, \(k-1\), are for the case when no parameters of the distribution are estimated. If \(p\) parameters are estimated by efficient maximum likelihood then the correct degrees of freedom are \(k-1-p\). If the parameters are estimated in a different way, then the \(dof\) can be between \(k-1-p\) and \(k-1\). However, it is also possible that the asymptotic distribution is not a \(\chi^2\), in which case this test is not appropriate.

References

[R671], [R672]

Examples

When just \(f\_obs\) is given, it is assumed that the expected frequencies are uniform and given by the mean of the observed frequencies.
>>> from scipy.stats import chisquare
>>> chisquare([16, 18, 16, 14, 12, 12])
(2.0, 0.84914503608460956)

With \(f_{\text{exp}}\) the expected frequencies can be given.

>>> chisquare([16, 18, 16, 14, 12, 12], f_exp=[16, 16, 16, 16, 16, 8])
(3.5, 0.62338762774958223)

When \(f_{\text{obs}}\) is 2-D, by default the test is applied to each column.

```python
>>> obs = np.array([[16, 18, 16, 14, 12, 12], [32, 24, 16, 28, 20, 24]]).T
>>> obs.shape
(6, 2)
>>> chisquare(obs)
(array([ 2. , 6.66666667]), array([ 0.84914504, 0.24663415]))
```

By setting \(\text{axis=}\text{None}\), the test is applied to all data in the array, which is equivalent to applying the test to the flattened array.

```python
>>> chisquare(obs, axis=None)
(23.31034482758621, 0.015975692534127565)
>>> chisquare(obs.ravel())
(23.31034482758621, 0.015975692534127565)
```

\(ddof\) is the change to make to the default degrees of freedom.

```python
>>> chisquare([16, 18, 16, 14, 12, 12], ddof=1)
(2.0, 0.73575888238467)
```

The calculation of the p-values is done by broadcasting the chi-squared statistic with \(ddof\).

```python
>>> chisquare([16, 18, 16, 14, 12, 12], ddof=[0,1,2])
(2.0, array([ 0.84914504, 0.73575888, 0.5724067 ]))
```

\(f_{\text{obs}}\) and \(f_{\text{exp}}\) are also broadcast. In the following, \(f_{\text{obs}}\) has shape (6,) and \(f_{\text{exp}}\) has shape (2, 6), so the result of broadcasting \(f_{\text{obs}}\) and \(f_{\text{exp}}\) has shape (2, 6). To compute the desired chi-squared statistics, we use \(\text{axis=1}\):

```python
>>> chisquare([16, 18, 16, 14, 12, 12],
... f_exp=[[16, 16, 16, 16, 16, 8], [8, 20, 20, 16, 12, 12]],
... axis=1)
(array([ 3.5 , 9.25]), array([ 0.62338763, 0.09949846]))
```

```python
scipy.stats.mstats.count_tied_groups(x, use_missing=False)
Counts the number of tied values.

Parameters

- **x**: sequence
  Sequence of data on which to counts the ties
  - **use_missing**: bool, optional
  Whether to consider missing values as tied.

Returns

- **count_tied_groups**: dict
  Returns a dictionary (nb of ties: nb of groups).

Examples

2050
Chapter 5. API Reference
```python
>>> from scipy.stats import mstats
>>> z = [0, 0, 0, 2, 2, 2, 3, 3, 4, 5, 6]
>>> mstats.count_tied_groups(z)
{2: 1, 3: 2}

In the above example, the ties were 0 (3x), 2 (3x) and 3 (2x).

```python
>>> z = np.ma.array([0, 0, 1, 2, 2, 2, 3, 3, 4, 5, 6])
>>> mstats.count_tied_groups(z)
{2: 1, 3: 1}
```

```python
>>> z[[1,-1]] = np.ma.masked
>>> mstats.count_tied_groups(z, use_missing=True)
{2: 2, 3: 1}
```

```
scipy.stats.mstats.describe (a, axis=0, ddof=0, bias=True)
Computes several descriptive statistics of the passed array.

Parameters

a : array_like
   Data array

axis : int or None, optional
   Axis along which to calculate statistics. Default 0. If None, compute over
   the whole array a.

ddof : int, optional
   degree of freedom (default 0); note that default ddof is different from the
   same routine in stats.describe

bias : bool, optional
   If False, then the skewness and kurtosis calculations are corrected for sta-
   tistical bias.

Returns

nobs : int
   (size of the data (discarding missing values)

minmax : (int, int)
   min, max

mean : float
   arithmetic mean

variance : float
   unbiased variance

skewness : float
   biased skewness

kurtosis : float
   biased kurtosis

Examples

```python
>>> from scipy.stats.mstats import describe
>>> ma = np.ma.array(range(6), mask=[0, 0, 0, 1, 1, 1])
>>> describe(ma)
DescribeResult(nobs=3, minmax=(masked_array(data = 0,
   mask = False,
   fill_value = 999999)
, masked_array(data = 2,
   mask = False,
   fill_value = 999999)
), mean=1.0, variance=0.6666666666666663, skewness=masked_array(data = 0.0,
   mask = False,
   fill_value = 1e+20)
, kurtosis=-1.5)

```

5.27. Statistical functions (scipy.stats)
**scipy.stats.mstats.f_oneway**(*args*)  
Performs a 1-way ANOVA, returning an F-value and probability given any number of groups. From Heiman, pp.394-7.

Usage: f_oneway(*args), where *args is 2 or more arrays, one per treatment group.

**Returns**
- statistic : float  
The computed F-value of the test.
- pvalue : float  
The associated p-value from the F-distribution.

**scipy.stats.mstats.find_repeats**(arr)
Find repeats in arr and return a tuple (repeats, repeat_count).

The input is cast to float64. Masked values are discarded.

**Parameters**
- arr : sequence  
Input array. The array is flattened if it is not 1D.

**Returns**
- repeats : ndarray  
Array of repeated values.
- counts : ndarray  
Array of counts.

**scipy.stats.mstats.friedmanchisquare**(*args*)  
Friedman Chi-Square is a non-parametric, one-way within-subjects ANOVA. This function calculates the Friedman Chi-square test for repeated measures and returns the result, along with the associated probability value.

Each input is considered a given group. Ideally, the number of treatments among each group should be equal. If this is not the case, only the first n treatments are taken into account, where n is the number of treatments of the smallest group. If a group has some missing values, the corresponding treatments are masked in the other groups. The test statistic is corrected for ties.

Masked values in one group are propagated to the other groups.

**Returns**
- statistic : float  
The test statistic.
- pvalue : float  
The associated p-value.

**scipy.stats.mstats.kendalltau**(x, y, use_ties=True, use_missing=False)
Computes Kendall’s rank correlation tau on two variables x and y.

**Parameters**
- x : sequence  
First data list (for example, time).
- y : sequence  
Second data list.
- use_ties : {True, False}, optional  
Whether ties correction should be performed.
- use_missing : {False, True}, optional  
Whether missing data should be allocated a rank of 0 (False) or the average rank (True)

**Returns**
- correlation : float  
Kendall tau
- pvalue : float  
Approximate 2-side p-value.

**scipy.stats.mstats.kendalltau_seasonal**(x)
Computes a multivariate Kendall’s rank correlation tau, for seasonal data.

**Parameters**
- x : 2-D ndarray
Array of seasonal data, with seasons in columns.

```
scipy.stats.mstats.kruskalwallis(*args)
```

Compute the Kruskal-Wallis H-test for independent samples

**Parameters**

- `sample1, sample2, ...` : array_like
  Two or more arrays with the sample measurements can be given as arguments.

**Returns**

- `statistic` : float
  The Kruskal-Wallis H statistic, corrected for ties

- `pvalue` : float
  The p-value for the test using the assumption that H has a chi square distribution

**Notes**

For more details on `kruskal`, see `stats.kruskal`.

```
scipy.stats.mstats.ks_twosamp(data1, data2, alternative='two-sided')
```

Computes the Kolmogorov-Smirnov test on two samples.

Missing values are discarded.

**Parameters**

- `data1` : array_like
  First data set

- `data2` : array_like
  Second data set

- `alternative` : {'two-sided', 'less', 'greater'}, optional
  Indicates the alternative hypothesis. Default is 'two-sided'.

**Returns**

- `d` : float
  Value of the Kolmogorov Smirnov test

- `p` : float
  Corresponding p-value.

```
scipy.stats.mstats.kurtosis(a, axis=0, fisher=True, bias=True)
```

Computes the kurtosis (Fisher or Pearson) of a dataset.

Kurtosis is the fourth central moment divided by the square of the variance. If Fisher’s definition is used, then 3.0 is subtracted from the result to give 0.0 for a normal distribution.

If bias is False then the kurtosis is calculated using k statistics to eliminate bias coming from biased moment estimators

Use `kurtosistest` to see if result is close enough to normal.

**Parameters**

- `a` : array
  data for which the kurtosis is calculated

- `axis` : int or None, optional
  Axis along which the kurtosis is calculated. Default is 0. If None, compute over the whole array `a`.

- `fisher` : bool, optional
  If True, Fisher’s definition is used (normal => 0.0). If False, Pearson’s definition is used (normal => 3.0).

- `bias` : bool, optional
  If False, then the calculations are corrected for statistical bias.

**Returns**

- `kurtosis` : array
  The kurtosis of values along an axis. If all values are equal, return -3 for Fisher’s definition and 0 for Pearson’s definition.
Notes

For more details about \textit{kurtosis}, see \textit{stats.kurtosis}.

\texttt{scipy.stats.mstats.kurtosistest(a, axis=0)}

Tests whether a dataset has normal kurtosis

\begin{itemize}
  \item \textbf{Parameters} \quad \texttt{a} : array
    \begin{itemize}
      \item array of the sample data
      \item \texttt{axis} : int or None, optional
        \begin{itemize}
          \item Axis along which to compute test. Default is 0. If None, compute over the whole array \texttt{a}.
        \end{itemize}
    \end{itemize}
  \item \textbf{Returns} \quad \texttt{statistic} : float
    \begin{itemize}
      \item The computed z-score for this test.
    \end{itemize}
  \item \texttt{pvalue} : float
    \begin{itemize}
      \item The 2-sided p-value for the hypothesis test
    \end{itemize}
\end{itemize}

Notes

For more details about \textit{kurtosistest}, see \textit{stats.kurtosistest}.

\texttt{scipy.stats.mstats.linregress(x, y=None)}

Calculate a linear least-squares regression for two sets of measurements.

\begin{itemize}
  \item \textbf{Parameters} \quad \texttt{x, y} : array_like
    \begin{itemize}
      \item Two sets of measurements. Both arrays should have the same length. If only \texttt{x} is given (and \texttt{y=None}), then it must be a two-dimensional array where one dimension has length 2. The two sets of measurements are then found by splitting the array along the length-2 dimension.
    \end{itemize}
  \item \textbf{Returns} \quad \texttt{slope} : float
    \begin{itemize}
      \item slope of the regression line
    \end{itemize}
  \item \texttt{intercept} : float
    \begin{itemize}
      \item intercept of the regression line
    \end{itemize}
  \item \texttt{rvalue} : float
    \begin{itemize}
      \item correlation coefficient
    \end{itemize}
  \item \texttt{pvalue} : float
    \begin{itemize}
      \item two-sided p-value for a hypothesis test whose null hypothesis is that the slope is zero, using Wald Test with t-distribution of the test statistic.
    \end{itemize}
  \item \texttt{stderr} : float
    \begin{itemize}
      \item Standard error of the estimated gradient.
    \end{itemize}
\end{itemize}

See also:

\texttt{scipy.optimize.curve_fit}

Use non-linear least squares to fit a function to data.

\texttt{scipy.optimize.leastsq}

Minimize the sum of squares of a set of equations.

Notes

Missing values are considered pair-wise: if a value is missing in \texttt{x}, the corresponding value in \texttt{y} is masked.

Examples

\begin{verbatim}
>>> import matplotlib.pyplot as plt
>>> from scipy import stats
>>> np.random.seed(12345678)
>>> x = np.random.random(10)
>>> y = np.random.random(10)
>>> slope, intercept, r_value, p_value, std_err = stats.linregress(x, y)
\end{verbatim}
To get coefficient of determination (r_squared)

```python
>>> print("r-squared:", r_value**2)
r-squared: 0.080402268539
```

Plot the data along with the fitted line

```python
>>> plt.plot(x, y, 'o', label='original data')
>>> plt.plot(x, intercept + slope*x, 'r', label='fitted line')
>>> plt.legend()
>>> plt.show()
```

```python
scipy.stats.mstats.mannwhitneyu(x, y, use_continuity=True)
Computes the Mann-Whitney statistic

Missing values in x and/or y are discarded.

Parameters

- **x**: sequence
  Input
- **y**: sequence
  Input
- **use_continuity**: {True, False}, optional
  Whether a continuity correction (1/2.) should be taken into account.

Returns

- **statistic**: float
  The Mann-Whitney statistics
- **pvalue**: float
  Approximate p-value assuming a normal distribution.

scipy.stats.mstats.plotting_positions(data, alpha=0.4, beta=0.4)
Returns plotting positions (or empirical percentile points) for the data.

Plotting positions are defined as \((i-\alpha)/(n+1-\alpha-\beta)\), where:

- \(i\) is the rank order statistics
- \(n\) is the number of unmasked values along the given axis
- \(\alpha\) and \(\beta\) are two parameters.

Typical values for \(\alpha\) and \(\beta\) are:

- \((0,1)\): \(p(k) = k/n\), linear interpolation of cdf (R, type 4)
\((0.5, 0.5) : p(k) = (k - 1/2)/n\), piecewise linear function (R, type 5)
\((0, 0) : p(k) = k/(n+1)\), Weibull (R type 6)
\((1, 1) : p(k) = (k-1)/(n-1)\), in this case, \(p(k) = \text{mode}[F(x[k])]\). That's R default (R type 7)
\((1/3, 1/3) : p(k) = (k - 1/3)/(n+1/3)\), then \(p(k) \sim \text{median}[F(x[k])]\). The resulting quantile estimates are approximately median-unbiased regardless of the distribution of \(x\). (R type 8)
\((3/8, 3/8) : p(k) = (k-3/8)/(n+1/4)\), Blom. The resulting quantile estimates are approximately unbiased if \(x\) is normally distributed (R type 9)
\((.4,.4) : \text{approximately quantile unbiased (Cunnane)}\)
\((.35,.35) : \text{APL, used with PWM}\)
\((.3175, .3175) : \text{used in scipy.stats.probplot}\)

**Parameters**

- **data** : array_like
  
  Input data, as a sequence or array of dimension at most 2.

- **alpha** : float, optional

  Plotting positions parameter. Default is 0.4.

- **beta** : float, optional

**Returns**

- **positions** : MaskedArray

  The calculated plotting positions.

```python
scipy.stats.mstats.mode(a, axis=0)
```

Returns an array of the modal (most common) value in the passed array.

**Parameters**

- **a** : array_like

  n-dimensional array of which to find mode(s).

- **axis** : int or None, optional

  Axis along which to operate. Default is 0. If None, compute over the whole array \(a\).

**Returns**

- **mode** : ndarray

  Array of modal values.

- **count** : ndarray

  Array of counts for each mode.

**Notes**

For more details, see `stats.mode`.

```python
scipy.stats.mstats.moment(a, moment=1, axis=0)
```

Calculates the nth moment about the mean for a sample.

**Parameters**

- **a** : array_like

  data

- **moment** : int, optional

  order of central moment that is returned

- **axis** : int or None, optional

  Axis along which the central moment is computed. Default is 0. If None, compute over the whole array \(a\).

**Returns**

- **n-th central moment** : ndarry or float

  The appropriate moment along the given axis or over all values if axis is None. The denominator for the moment calculation is the number of observations, no degrees of freedom correction is done.

**Notes**

For more details about `moment`, see `stats.moment`. 

---

2056 Chapter 5. API Reference
scipy.stats.mstats.mquantiles(a, prob=[0.25, 0.5, 0.75], alphap=0.4, betap=0.4, axis=None, limit=())

Computes empirical quantiles for a data array.

Samples quantile are defined by \( Q(p) = (1-gamma)*x[j] + gamma*x[j+1] \), where \( x[j] \) is the \( j \)-th order statistic, and gamma is a function of \( j = \text{floor}(n*p + m), m = \text{alphap} + p*(1 - \text{alphap} - \text{betap}) \) and \( g = n*p + m - j \).

Reinterpreting the above equations to compare to R lead to the equation: \( p(k) = (k - \text{alphap})/(n + 1 - \text{alphap} - \text{betap}) \)

**Typical values of (alphap,betap) are:**

- \((0,1): p(k) = k/n\): linear interpolation of cdf (R type 4)
- \((0.5,0.5): p(k) = (k - 1/2.)/n\): piecewise linear function (R type 5)
- \((0,0): p(k) = k/(n+1)\): (R type 6)
- \((1,1): p(k) = (k-1)/(n-1)\): p(k) = mode[F(x[k])]. (R type 7, R default)
- \((1/3,1/3): p(k) = (k-1/3)/(n+1/3): Then p(k) ~ median[F(x[k])]. The resulting quantile estimates are approximately median-unbiased regardless of the distribution of x. (R type 8)
- \((3/8,3/8): p(k) = (k-3/8)/(n+1/4): Blom. The resulting quantile estimates are approximately unbiased if x is normally distributed (R type 9)
- \((.4,.4): approximately quantile unbiased (Cunnane)
- \((.35,.35): APL, used with PWM

**Parameters**

- **a**: array_like
  - Input data, as a sequence or array of dimension at most 2.
- **prob**: array_like, optional
  - List of quantiles to compute.
- **alphap**: float, optional
  - Plotting positions parameter, default is 0.4.
- **betap**: float, optional
  - Plotting positions parameter, default is 0.4.
- **axis**: int, optional
  - Axis along which to perform the trimming. If None (default), the input array is first flattened.
- **limit**: tuple, optional
  - Tuple of (lower, upper) values. Values of \( a \) outside this open interval are ignored.

**Returns**

- **mquantiles**: MaskedArray
  - An array containing the calculated quantiles.

**Notes**

This formulation is very similar to R except the calculation of \( m \) from alphap and betap, where in R \( m \) is defined with each type.

**References**

[R673], [R674]

**Examples**

```python
>>> from scipy.stats.mstats import mquantiles
>>> a = np.array([6., 47., 49., 15., 42., 41., 7., 39., 43., 40., 36.])
>>> mquantiles(a)
array([ 19.2, 40.0, 42.8])
```
Using a 2D array, specifying axis and limit.

```python
>>> data = np.array([[ 6.,  7.,  1.],
...                   [ 47., 15.,  2.],
...                   [ 49., 36.,  3.],
...                   [ 15., 39.,  4.],
...                   [ 42., 40., -999.],
...                   [ 41., 41., -999.],
...                   [ 7.,  999., -999.],
...                   [39., -999., -999.],
...                   [43., -999., -999.],
...                   [40., -999., -999.],
...                   [36., -999., -999.]]

>>> print(mquantiles(data, axis=0, limit=(0, 50)))
[[ 19.2 14.6 1.45]
 [ 40. 37.5 2.5 ]
 [42.8 40.05 3.55]]

>>> data[:, 2] = -999.

>>> print(mquantiles(data, axis=0, limit=(0, 50)))
[[19.200000000000003 14.6 --]
 [40.0 37.5 --]
 [42.800000000000004 40.05 --]]
```

scipy.stats.mstats.msign(x)

Returns the sign of x, or 0 if x is masked.

scipy.stats.mstats.normaltest(a, axis=0)

Tests whether a sample differs from a normal distribution.

Parameters

- `a`: array_like
  The array containing the data to be tested.

- `axis`: int or None, optional
  Axis along which to compute test. Default is 0. If None, compute over the whole array `a`.

Returns

- `statistic`: float or array
  \( s^2 + k^2 \), where \( s \) is the z-score returned by `skewtest` and \( k \) is the z-score returned by `kurtosistest`.

- `pvalue`: float or array
  A 2-sided chi squared probability for the hypothesis test.

Notes

For more details about `normaltest`, see `stats.normaltest`.

scipy.stats.mstats.obrientransform(*args)

Computes a transform on input data (any number of columns). Used to test for homogeneity of variance prior to running one-way stats. Each array in *args is one level of a factor. If an `f_oneway()` run on the transformed data and found significant, variances are unequal. From Maxwell and Delaney, p.112.

Returns: transformed data for use in an ANOVA

scipy.stats.mstats.pearsonr(x, y)

Calculates a Pearson correlation coefficient and the p-value for testing non-correlation.

The Pearson correlation coefficient measures the linear relationship between two datasets. Strictly speaking, Pearson’s correlation requires that each dataset be normally distributed. Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply an exact linear relationship. Positive correlations imply that as \( x \) increases, so does \( y \). Negative correlations imply that as \( x \) increases, \( y \) decreases.
The p-value roughly indicates the probability of an uncorrelated system producing datasets that have a Pearson correlation at least as extreme as the one computed from these datasets. The p-values are not entirely reliable but are probably reasonable for datasets larger than 500 or so.

**Parameters**

- **x**: 1-D array_like
  Input
- **y**: 1-D array_like
  Input

**Returns**

- **pearsonr**: float
  Pearson’s correlation coefficient, 2-tailed p-value.

**References**

http://www.statsoft.com/textbook/glosp.html#Pearson%20Correlation

`scipy.stats.mstats.pointbiserialr(x, y)`
Calculates a point biserial correlation coefficient and its p-value.

**Parameters**

- **x**: array_like of bools
  Input array.
- **y**: array_like
  Input array.

**Returns**

- **correlation**: float
  R value
- **pvalue**: float
  2-tailed p-value

**Notes**

Missing values are considered pair-wise: if a value is missing in x, the corresponding value in y is masked.

For more details on `pointbiserialr`, see `stats.pointbiserialr`.

`scipy.stats.mstats.rankdata(data, axis=None, use_missing=False)`
Returns the rank (also known as order statistics) of each data point along the given axis.

If some values are tied, their rank is averaged. If some values are masked, their rank is set to 0 if use_missing is False, or set to the average rank of the unmasked values if use_missing is True.

**Parameters**

- **data**: sequence
  Input data. The data is transformed to a masked array
- **axis**: {None, int}, optional
  Axis along which to perform the ranking. If None, the array is first flattened. An exception is raised if the axis is specified for arrays with a dimension larger than 2
- **use_missing**: bool, optional
  Whether the masked values have a rank of 0 (False) or equal to the average rank of the unmasked values (True).

`scipy.stats.mstats.scoreatpercentile(data, per, limit=(), alphap=0.4, betap=0.4)`
Calculate the score at the given 'per' percentile of the sequence a. For example, the score at per=50 is the median.

This function is a shortcut to `mquantile`

`scipy.stats.mstats.sem(a, axis=0, ddof=1)`
Calculates the standard error of the mean of the input array.

Also sometimes called standard error of measurement.

**Parameters**

- **a**: array_like
  An array containing the values for which the standard error is returned.
**axis** : int or None, optional
If axis is None, ravel a first. If axis is an integer, this will be the axis over which to operate. Defaults to 0.

**ddof** : int, optional
Delta degrees-of-freedom. How many degrees of freedom to adjust for bias in limited samples relative to the population estimate of variance. Defaults to 1.

**Returns**

\[s\] : ndarray or float
The standard error of the mean in the sample(s), along the input axis.

**Notes**

The default value for **ddof** changed in scipy 0.15.0 to be consistent with **stats.sem** as well as with the most common definition used (like in the R documentation).

**Examples**

Find standard error along the first axis:

```python
>>> from scipy import stats
>>> a = np.arange(20).reshape(5,4)
>>> print(stats.mstats.sem(a))
[2.8284271247461903 2.8284271247461903 2.8284271247461903 2.8284271247461903]
```

Find standard error across the whole array, using n degrees of freedom:

```python
>>> print(stats.mstats.sem(a, axis=None, ddof=0))
1.2893796958227628
```

**scipy.stats.mstats.skew(a, axis=0, bias=True)**

Computes the skewness of a data set.

**Parameters**

\[a\] : ndarray
data

**axis** : int or None, optional
Axis along which skewness is calculated. Default is 0. If None, compute over the whole array \[a\].

**bias** : bool, optional
If False, then the calculations are corrected for statistical bias.

**Returns**

\[skewness\] : ndarray
The skewness of values along an axis, returning 0 where all values are equal.

**Notes**

For more details about **skew**, see **stats.skew**.

**scipy.stats.mstats.skewtest(a, axis=0)**

Tests whether the skew is different from the normal distribution.

**Parameters**

\[a\] : array
The data to be tested

**axis** : int or None, optional
Axis along which statistics are calculated. Default is 0. If None, compute over the whole array \[a\].

**Returns**

\[statistic\] : float
The computed z-score for this test.

\[pvalue\] : float
a 2-sided p-value for the hypothesis test
Notes

For more details about `skewtest`, see `stats.skewtest`.

```python
scipy.stats.mstats.spearmanr(x, y, use_ties=True)
```

Calculates a Spearman rank-order correlation coefficient and the p-value to test for non-correlation.

The Spearman correlation is a nonparametric measure of the linear relationship between two datasets. Unlike the Pearson correlation, the Spearman correlation does not assume that both datasets are normally distributed. Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply a monotonic relationship. Positive correlations imply that as `x` increases, so does `y`. Negative correlations imply that as `x` increases, `y` decreases.

Missing values are discarded pair-wise: if a value is missing in `x`, the corresponding value in `y` is masked.

The p-value roughly indicates the probability of an uncorrelated system producing datasets that have a Spearman correlation at least as extreme as the one computed from these datasets. The p-values are not entirely reliable but are probably reasonable for datasets larger than 500 or so.

**Parameters**

- `x`: array_like
  - The length of `x` must be > 2.
- `y`: array_like
  - The length of `y` must be > 2.
- `use_ties`: bool, optional
  - Whether the correction for ties should be computed.

**Returns**

- `correlation`: float
  - Spearman correlation coefficient
- `pvalue`: float
  - 2-tailed p-value.

References

```python
scipy.stats.mstats.theilslopes(y, x=None, alpha=0.95)
```

Computes the Theil-Sen estimator for a set of points `(x, y)`.

`theilslopes` implements a method for robust linear regression. It computes the slope as the median of all slopes between paired values.

**Parameters**

- `y`: array_like
  - Dependent variable.
- `x`: array_like or None, optional
  - Independent variable. If None, use `arange(len(y))` instead.
- `alpha`: float, optional
  - Confidence degree between 0 and 1. Default is 95% confidence. Note that `alpha` is symmetric around 0.5, i.e. both 0.1 and 0.9 are interpreted as “find the 90% confidence interval”.

**Returns**

- `medslope`: float
  - Theil slope.
- `medintercept`: float
  - Intercept of the Theil line, as `median(y) - medslope*median(x)`.
- `lo_slope`: float
  - Lower bound of the confidence interval on `medslope`.
- `up_slope`: float
  - Upper bound of the confidence interval on `medslope`.  

5.27. Statistical functions (scipy.stats)  2061
Notes
For more details on theilslopes, see stats.theilslopes.

```
scipy.stats.mstats.tmax(a, upperlimit=None, axis=0, inclusive=True)
```

This function computes the maximum value of an array along a given axis, while ignoring values larger than a specified upper limit.

**Parameters**
- `a`: array_like
  array of values
- `upperlimit`: None or float, optional
  Values in the input array greater than the given limit will be ignored. When upperlimit is None, then all values are used. The default value is None.
- `axis`: int or None, optional
  Axis along which to operate. Default is 0. If None, compute over the whole array `a`.
- `inclusive`: {True, False}, optional
  This flag determines whether values exactly equal to the upper limit are included. The default value is True.

**Returns**
- `tmax`: float, int or ndarray

Notes
For more details on tmax, see stats.tmax.

```
scipy.stats.mstats.tmean(a, limits=None, inclusive=(True, True), axis=None)
```

Compute the trimmed mean.

**Parameters**
- `a`: array_like
  Array of values.
- `limits`: None or (lower limit, upper limit), optional
  Values in the input array less than the lower limit or greater than the upper limit will be ignored. When limits is None (default), then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval.
- `inclusive`: (bool, bool), optional
  A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).
- `axis`: int or None, optional
  Axis along which to operate. If None, compute over the whole array. Default is None.

**Returns**
- `tmean`: float

Notes
For more details on tmean, see stats.tmean.

```
scipy.stats.mstats.tmin(a, lowerlimit=None, axis=0, inclusive=True)
```

Compute the trimmed minimum

**Parameters**
- `a`: array_like
  array of values
- `lowerlimit`: None or float, optional
  Values in the input array less than the given limit will be ignored. When lowerlimit is None, then all values are used. The default value is None.
- `axis`: int or None, optional
Axis along which to operate. Default is 0. If None, compute over the whole array \( a \).

*inclusive* : \{True, False\}, optional

This flag determines whether values exactly equal to the lower limit are included. The default value is True.

**Returns**

* \( \text{tmin} \) : float, int or ndarray

**Notes**

For more details on \( \text{tmin} \), see \texttt{stats.tmin}.

\texttt{scipy.stats.mstats.trim(a, limits=None, inclusive=(True, True), relative=False, axis=None)}

Trims an array by masking the data outside some given limits.

Returns a masked version of the input array.

**Parameters**

*a* : sequence

Input array

*limits* : \{None, tuple\}, optional

If \( \text{relative} \) is False, tuple (lower limit, upper limit) in absolute values. Values of the input array lower (greater) than the lower (upper) limit are masked. If \( \text{relative} \) is True, tuple (lower percentage, upper percentage) to cut on each side of the array, with respect to the number of unmasked data. Noting \( n \) the number of unmasked data before trimming, the \( n*\text{limits}[0] \)th smallest data and the \( n*\text{limits}[1] \)th largest data are masked, and the total number of unmasked data after trimming is \( n*(1.-\text{sum(limits)}) \). In each case, the value of one limit can be set to None to indicate an open interval. If limits is None, no trimming is performed

*inclusive* : \{\text{bool, bool} \} tuple, optional

If \( \text{relative} \) is False, tuple indicating whether values exactly equal to the absolute limits are allowed. If \( \text{relative} \) is True, tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False).

*relative* : bool, optional

Whether to consider the limits as absolute values (False) or proportions to cut (True).

*axis* : int, optional

Axis along which to trim.

**Examples**

```python
>>> from scipy.stats.mstats import trim
>>> z = [1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
>>> print(trim(z,(3,8)))
[-- -- 3 4 5 6 7 8 -- --]
>>> print(trim(z,(0.1,0.2),relative=True))
[-- 2 3 4 5 6 7 8 -- --]
```

\texttt{scipy.stats.mstats.trim(a, limits=None, inclusive=(True, True))}

Trims an array by masking the data outside some given limits.

Returns a masked version of the input array.

**Parameters**

*a* : array_like

Input array.

*limits* : \{None, tuple\}, optional

5.27. Statistical functions (\texttt{scipy.stats})
Tuple of (lower limit, upper limit) in absolute values. Values of the input array lower (greater) than the lower (upper) limit will be masked. A limit is None indicates an open interval.

inclusive : (bool, bool) tuple, optional
Tuple of (lower flag, upper flag), indicating whether values exactly equal to the lower (upper) limit are allowed.

```python
scipy.stats.mstats.trimboth(data, proportiontocut=0.2, inclusive=(True, True), axis=None)
```

Trims the smallest and largest data values.

Trims the data by masking the int(proportiontocut * n) smallest and int(proportiontocut * n) largest values of data along the given axis, where n is the number of unmasked values before trimming.

**Parameters**
- **data**: ndarray
  Data to trim.
- **proportiontocut**: float, optional
  Percentage of trimming (as a float between 0 and 1). If n is the number of unmasked values before trimming, the number of values after trimming is (1 - 2*proportiontocut) * n. Default is 0.2.
- **inclusive**: {(bool, bool) tuple}, optional
  Tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False).
- **axis**: int, optional
  Axis along which to perform the trimming. If None, the input array is first flattened.

```python
scipy.stats.mstats.trim_r(a, limits=None, inclusive=(True, True), axis=None)
```

Trims an array by masking some proportion of the data on each end. Returns a masked version of the input array.

**Parameters**
- **a**: sequence
  Input array.
- **limits**: {{0.1,0.1}, tuple of float}, optional
  Tuple (lower percentage, upper percentage) to cut on each side of the array, with respect to the number of unmasked data. If n is the number of unmasked data before trimming, the values smaller than n * limits[0] and the values larger than n * `limits[1]` are masked, and the total number of unmasked data after trimming is n * (1. -sum(limits)). In each case, the value of one limit can be set to None to indicate an open interval. If limits is None, no trimming is performed.
- **inclusive**: {{bool, bool} tuple} optional
  Tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False).
- **axis**: int, optional
  Axis along which to trim.

**Returns**
- **trimmed_std**: scalar of ndarray

```python
scipy.stats.mstats.trim(a, limits=None, inclusive=(True, True), axis=None)
```

Trims an array by masking some proportion of the data on each end. Returns a masked version of the input array.

**Parameters**
- **a**: sequence
  Input array.
- **limits**: {{None, tuple}, optional
  Tuple of the percentages to cut on each side of the array, with respect to the number of unmasked data, as floats between 0. and 1. Noting n the number of unmasked data before trimming, the (n*limits[0])th smallest data and the (n*limits[1])th largest data are masked, and the total number of unmasked
data after trimming is \( n \times (1. - \text{sum}(\text{limits})) \). The value of one limit can be set to None to indicate an open interval.

**inclusive**: \(((\text{True}, \text{True}) \text{ tuple})\), optional

Tuple of flags indicating whether the number of data being masked on the left (right) end should be truncated (True) or rounded (False) to integers.

**axis**: \([\text{None}, \text{int}]\), optional

Axis along which to trim. If None, the whole array is trimmed, but its shape is maintained.

```python
scipy.stats.mstats.trimtail(data, proportiontocut=0.2, tail='left', inclusive=((True, True), axis=None)
```

Trims the data by masking values from one tail.

**Parameters**

- **data**: array_like
  Data to trim.

- **proportiontocut**: float, optional
  Percentage of trimming. If \( n \) is the number of unmasked values before trimming, the number of values after trimming is \((1 - \text{proportiontocut}) \times n\). Default is 0.2.

- **tail**: {'left', 'right'}, optional
  If ‘left’ the \text{proportiontocut} lowest values will be masked. If ‘right’ the \text{proportiontocut} highest values will be masked. Default is ‘left’.

- **inclusive**: \((\text{bool}, \text{bool}) \text{ tuple}\), optional
  Tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False). Default is (True, True).

- **axis**: int, optional
  Axis along which to perform the trimming. If None, the input array is first flattened. Default is None.

**Returns**

- **trimtail**: ndarray
  Returned array of same shape as \text{data} with masked tail values.

```python
scipy.stats.mstats.tsem(a, limits=None, inclusive=((True, True), axis=0, ddof=1)
```

Compute the trimmed standard error of the mean.

This function finds the standard error of the mean for given values, ignoring values outside the given limits.

**Parameters**

- **a**: array_like
  array of values

- **limits**: None or (lower limit, upper limit), optional
  Values in the input array less than the lower limit or greater than the upper limit will be ignored. When limits is None, then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval. The default value is None.

- **inclusive**: \((\text{bool}, \text{bool})\), optional
  A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).

- **axis**: int or None, optional
  Axis along which to operate. If None, compute over the whole array. Default is zero.

- **ddof**: int, optional
  Delta degrees of freedom. Default is 1.

**Notes**

For more details on \text{tsem}, see \text{stats.tsem}.
`scipy.stats.mstats.ttest_onesamp(a, popmean, axis=0)`  
Calculates the T-test for the mean of ONE group of scores.

**Parameters**  
- `a`: array_like  
  sample observation  
- `popmean`: float or array_like  
  expected value in null hypothesis, if array_like than it must have the same shape as `a` excluding the axis dimension  
- `axis`: int or None, optional  
  Axis along which to compute test. If None, compute over the whole array

**Returns**  
- `statistic`: float or array  
  t-statistic  
- `pvalue`: float or array  
  two-tailed p-value

**Notes**

For more details on `ttest_1samp`, see `stats.ttest_1samp`.

`scipy.stats.mstats.ttest_ind(a, b, axis=0, equal_var=True)`  
Calculates the T-test for the means of TWO INDEPENDENT samples of scores.

**Parameters**  
- `a`, `b`: array_like  
  The arrays must have the same shape, except in the dimension corresponding to `axis` (the first, by default).  
- `axis`: int or None, optional  
  Axis along which to compute test. If None, compute over the whole arrays, `a`, and `b`.  
- `equal_var`: bool, optional  
  If True, perform a standard independent 2 sample test that assumes equal population variances. If False, perform Welch’s t-test, which does not assume equal population variance. .. versionadded:: 0.17.0

**Returns**  
- `statistic`: float or array  
  The calculated t-statistic.  
- `pvalue`: float or array  
  The two-tailed p-value.

**Notes**

For more details on `ttest_ind`, see `stats.ttest_ind`.

`scipy.stats.mstats.ttest_rel(a, b, axis=0)`  
Calculates the T-test on TWO RELATED samples of scores, `a` and `b`.

**Parameters**  
- `a`, `b`: array_like  
  The arrays must have the same shape.  
- `axis`: int or None, optional  
  Axis along which to compute test. If None, compute over the whole arrays, `a`, and `b`.

**Returns**  
- `statistic`: float or array  
  t-statistic  
- `pvalue`: float or array  
  two-tailed p-value

**Notes**

For more details on `ttest_rel`, see `stats.ttest_rel`. 
scipy.stats.mstats.tvar \(a, \text{limits} = \text{None}, \text{inclusive} = (\text{True}, \text{True}), \text{axis} = 0, \text{ddof} = 1\)

Compute the trimmed variance

This function computes the sample variance of an array of values, while ignoring values which are outside of given \textit{limits}.

**Parameters**
- \(a\) : array_like
  Array of values.
- \text{limits} : None or (lower limit, upper limit), optional
  Values in the input array less than the lower limit or greater than the upper limit will be ignored. When \text{limits} is None, then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval. The default value is None.
- \text{inclusive} : (bool, bool), optional
  A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).
- \text{axis} : int or None, optional
  Axis along which to operate. If None, compute over the whole array. Default is zero.
- \text{ddof} : int, optional
  Delta degrees of freedom. Default is 1.

**Returns**
- \(tvar\) : float
  Trimmed variance.

**Notes**

For more details on \textit{tvar}, see \text{stats.tvar}.

scipy.stats.mstats.variation \(a, \text{axis} = 0\)

Computes the coefficient of variation, the ratio of the biased standard deviation to the mean.

**Parameters**
- \(a\) : array_like
  Input array.
- \text{axis} : int or None, optional
  Axis along which to calculate the coefficient of variation. Default is 0. If None, compute over the whole array \(a\).

**Returns**
- \(\text{variation}\) : ndarray
  The calculated variation along the requested axis.

**Notes**

For more details about \textit{variation}, see \text{stats.variation}.

scipy.stats.mstats.winsorize \(a, \text{limits} = \text{None}, \text{inclusive} = (\text{True}, \text{True}), \text{inplace} = \text{False}, \text{axis} = \text{None}\)

Returns a Winsorized version of the input array.

The (limits[0])th lowest values are set to the (limits[0])th percentile, and the (limits[1])th highest values are set to the (1 - limits[1])th percentile. Masked values are skipped.

**Parameters**
- \(a\) : sequence
  Input array.
- \text{limits} : \{None, tuple of float\}, optional
  Tuple of the percentages to cut on each side of the array, with respect to the number of unmasked data, as floats between 0. and 1. Noting \(n\) the number of unmasked data before trimming, the \((n*\text{limits}[0])\)th smallest data and the \((n*\text{limits}[1])\)th largest data are masked, and the total number of unmasked data after trimming is \(n*\text{(1.-sum(limits))}\) The value of one limit can be set to None to indicate an open interval.

5.27. Statistical functions (scipy.stats) 2067
inclusive : {(True, True) tuple}, optional
    Tuple indicating whether the number of data being masked on each side
    should be rounded (True) or truncated (False).

inplace : {False, True}, optional
    Whether to winsorize in place (True) or to use a copy (False).

axis : {None, int}, optional
    Axis along which to trim. If None, the whole array is trimmed, but its shape
    is maintained.

Notes
This function is applied to reduce the effect of possibly spurious outliers by limiting the extreme values.

scipy.stats.mstats.zmap(scores, compare, axis=0, ddof=0)
Calculate the relative z-scores.

Parameters
scores : array_like
    The input for which z-scores are calculated.

compare : array_like
    The input from which the mean and standard deviation of the normalization
    are taken; assumed to have the same dimension as scores.

axis : int or None, optional
    Axis over which mean and variance of compare are calculated. Default is
    0. If None, compute over the whole array scores.

ddf : int, optional
    Degrees of freedom correction in the calculation of the standard deviation.
    Default is 0.

Returns
zscore : array_like
    Z-scores, in the same shape as scores.

Notes
This function preserves ndarray subclasses, and works also with matrices and masked arrays (it uses asanyarray
instead of asarray for parameters).

Examples

```python
>>> from scipy.stats import zmap
>>> a = [0.5, 2.0, 2.5, 3]
>>> b = [0, 1, 2, 3, 4]
>>> zmap(a, b, axis=0)
array([-1.06066017, 0. , 0.35355339, 0.70710678])
```

scipy.stats.mstats.zscore(a, axis=0, ddof=0)
Calculate the z score of each value in the sample, relative to the sample mean and standard deviation.

Parameters
a : array_like
    An array like object containing the sample data.

axis : int or None, optional
    Axis along which to operate. Default is 0. If None, compute over the whole
    array a.

ddf : int, optional
    Degrees of freedom correction in the calculation of the standard deviation.
    Default is 0.

Returns
zscore : array_like
    The z-scores, standardized by mean and standard deviation of input array a.
Notes

This function preserves ndarray subclasses, and works also with matrices and masked arrays (it uses asanyarray instead of asarray for parameters).

Examples

```python
>>> a = np.array([0.7972, 0.0767, 0.4383, 0.7866, 0.8091,
                 ... 0.1954, 0.6307, 0.6599, 0.1065, 0.0508])
>>> from scipy import stats
>>> stats.zscore(a)
array([-1.1273,  1.2470,  1.0923,  1.1664, -0.8559,  0.5786,
        0.6748, -1.1488, -1.3324])
```

Computing along a specified axis, using n-1 degrees of freedom (ddof=1) to calculate the standard deviation:

```python
>>> b = np.array([[[0.3148, 0.0478, 0.6243, 0.4608],
                 ... [0.7149, 0.0775, 0.6072, 0.9656],
                 ... [0.6341, 0.1403, 0.9759, 0.4064],
                 ... [0.5918, 0.6948, 0.904 , 0.3721],
                 ... [0.0921, 0.2481, 0.1188, 0.1366]]])
>>> stats.zscore(b, axis=1, ddof=1)
array([[-0.1926, -1.2842,  1.0726,  0.4042],
        [ 0.3305, -1.3738,  1.2328, -0.3748],
        [-0.2209,  0.2447,  1.1904, -1.2141],
        [-0.8278,  1.4457, -0.4387, -0.1793]])
```

`scipy.stats.mstats.compare_medians_ms (group_1, group_2, axis=None)`

Compares the medians from two independent groups along the given axis.

The comparison is performed using the McKean-Schrader estimate of the standard error of the medians.

Parameters

- **group_1**: array_like
  - First dataset. Has to be of size >=7.

- **group_2**: array_like
  - Second dataset. Has to be of size >=7.

- **axis**: int, optional
  - Axis along which the medians are estimated. If None, the arrays are flattened. If axis is not None, then group_1 and group_2 should have the same shape.

Returns

- **compare_medians_ms**: {float, ndarray}
  - If axis is None, then returns a float, otherwise returns a 1-D ndarray of floats with a length equal to the length of group_1 along axis.

`scipy.stats.mstats.gmean (a, axis=0, dtype=None)`

Compute the geometric mean along the specified axis.

Return the geometric average of the array elements. That is: n-th root of (x1 * x2 * ... * xn)

Parameters

- **a**: array_like
  - Input array or object that can be converted to an array.

- **axis**: int or None, optional
  - Axis along which the geometric mean is computed. Default is 0. If None, compute over the whole array a.

- **dtype**: dtype, optional
  - Type of the returned array and of the accumulator in which the elements are summed. If dtype is not specified, it defaults to the dtype of a, unless a
has an integer dtype with a precision less than that of the default platform integer. In that case, the default platform integer is used.

**Returns**

- `gmean`: ndarray
  - see dtype parameter above

**See also:**

- `numpy.mean`: Arithmetic average
- `numpy.average`: Weighted average
- `hmean`: Harmonic mean

**Notes**

The geometric average is computed over a single dimension of the input array, axis=0 by default, or all values in the array if axis=None. float64 intermediate and return values are used for integer inputs.

Use masked arrays to ignore any non-finite values in the input or that arise in the calculations such as Not a Number and infinity because masked arrays automatically mask any non-finite values.

**Examples**

```python
>>> from scipy.stats import gmean
>>> gmean([1, 4])
2.0
>>> gmean([1, 2, 3, 4, 5, 6, 7])
3.3800151591412964
```

*scipy.stats.mstats.hdmedian*(`data`, `axis=-1`, `var=False`)  
Returns the Harrell-Davis estimate of the median along the given axis.

**Parameters**

- `data`: ndarray  
  Data array.
- `axis`: int, optional  
  Axis along which to compute the quantiles. If None, use a flattened array.
- `var`: bool, optional  
  Whether to return the variance of the estimate.

**Returns**

- `hdmedian`: MaskedArray  
  The median values. If var=True, the variance is returned inside the masked array. E.g. for a 1-D array the shape change from (1,) to (2,).

*scipy.stats.mstats.hdquantiles*(`data`, `prob=[0.25, 0.5, 0.75]`, `axis=None`, `var=False`)  
Computes quantile estimates with the Harrell-Davis method.

The quantile estimates are calculated as a weighted linear combination of order statistics.

**Parameters**

- `data`: array_like  
  Data array.
- `prob`: sequence, optional  
  Sequence of quantiles to compute.
- `axis`: int or None, optional  
  Axis along which to compute the quantiles. If None, use a flattened array.
- `var`: bool, optional  
  Whether to return the variance of the estimate.

**Returns**

- `hdquantiles`: MaskedArray  
  A (p,) array of quantiles (if var is False), or a (2,p) array of quantiles and variances (if var is True), where p is the number of quantiles.

**See also:**

- `hdquantiles_sd`
The standard error of the Harrell-Davis quantile estimates by jackknife.

**Parameters**
- **data**: array_like
  Data array.
- **prob**: sequence, optional
  Sequence of quantiles to compute.
- **axis**: int, optional

**Returns**
- **hdquantiles_sd**: MaskedArray
  Axis along which to compute the quantiles. If None, use a flattened array.
  Standard error of the Harrell-Davis quantile estimates.

See also:
- hdquantiles

Calculates the harmonic mean along the specified axis.

That is: \( \frac{n}{(1/x_1 + 1/x_2 + \ldots + 1/x_n)} \)

**Parameters**
- **a**: array_like
  Input array, masked array or object that can be converted to an array.
- **axis**: int or None, optional
  Axis along which the harmonic mean is computed. Default is 0. If None, compute over the whole array \( a \).
- **dtype**: dtype, optional
  Type of the returned array and of the accumulator in which the elements are summed. If \( dtype \) is not specified, it defaults to the dtype of \( a \), unless \( a \) has an integer \( dtype \) with a precision less than that of the default platform integer. In that case, the default platform integer is used.

**Returns**
- **hmean**: ndarray
  see \( dtype \) parameter above

See also:
- numpy.mean
  Arithmetic average
- numpy.average
  Weighted average
- gmean
  Geometric mean

**Notes**

The harmonic mean is computed over a single dimension of the input array, \( axis=0 \) by default, or all values in the array if \( axis=None \). float64 intermediate and return values are used for integer inputs.

Use masked arrays to ignore any non-finite values in the input or that arise in the calculations such as Not a Number and infinity.

**Examples**

```python
>>> from scipy.stats import hmean
>>> hmean([1, 4])
1.6000000000000001
>>> hmean([1, 2, 3, 4, 5, 6, 7])
2.6997245179063363
```

Calculates an estimate of the lower and upper quartiles.

Uses the ideal fourths algorithm.

---

5.27. Statistical functions (**scipy.stats**) 2071
### Parameters
- **data**: array_like  
  Input array.
- **axis**: int, optional  
  Axis along which the quartiles are estimated. If None, the arrays are flattened.

### Returns
- **idealfourths**: list of floats, masked array  
  Returns the two internal values that divide `data` into four parts using the ideal fourths algorithm either along the flattened array (if `axis` is None) or along `axis` of `data`.  

#### scipy.stats.mstats.kruskal (*args*)
Compute the Kruskal-Wallis H-test for independent samples

- **Parameters**  
  - **sample1, sample2, ...**: array_like  
    Two or more arrays with the sample measurements can be given as arguments.
- **Returns**  
  - **statistic**: float  
    The Kruskal-Wallis H statistic, corrected for ties.
  - **pvalue**: float  
    The p-value for the test using the assumption that H has a chi square distribution.

#### Notes
For more details on `kruskal`, see `stats.kruskal`.

#### scipy.stats.mstats.ks_2samp (data1, data2, alternative='two-sided')
Computes the Kolmogorov-Smirnov test on two samples.

- **Parameters**  
  - **data1**: array_like  
    First data set.
  - **data2**: array_like  
    Second data set.
  - **alternative**: {'two-sided', 'less', 'greater'}, optional  
    Indicates the alternative hypothesis. Default is 'two-sided'.
- **Returns**  
  - **d**: float  
    Value of the Kolmogorov Smirnov test.
  - **p**: float  
    Corresponding p-value.

#### scipy.stats.mstats.median_cihs (data, alpha=0.05, axis=None)
Computes the alpha-level confidence interval for the median of the data.

- **Parameters**  
  - **data**: array_like  
    Input data. Masked values are discarded. The input should be 1D only, or `axis` should be set to None.
  - **alpha**: float, optional  
    Confidence level of the intervals.
  - **axis**: int or None, optional  
    Axis along which to compute the quantiles. If None, use a flattened array.
- **Returns**  
  - **median_cihs**:  
    Alpha level confidence interval.

#### scipy.stats.mstats.meppf (data, alpha=0.4, beta=0.4)
Returns plotting positions (or empirical percentile points) for the data.

Plotting positions are defined as \((i-\alpha)/(n+1-\alpha-\beta)\), where:
• is the rank order statistics
• n is the number of unmasked values along the given axis
• alpha and beta are two parameters.

Typical values for alpha and beta are:

• (0,1): \( p(k) = \frac{k}{n} \), linear interpolation of cdf (R, type 4)
• (.5,.5): \( p(k) = \frac{(k-1/2)}{n} \), piecewise linear function (R, type 5)
• (0,0): \( p(k) = \frac{k}{n+1} \), Weibull (R type 6)
• (1,1): \( p(k) = \frac{(k-1)}{n-1} \), in this case, \( p(k) = \text{mode}[F(x[k])] \).
  That's R default (R type 7)
• (1/3,1/3): \( p(k) = \frac{(k-1/3)}{n+1/3} \), then \( p(k) \sim \text{median}[F(x[k])] \). The resulting quantile estimates are approximately median-unbiased regardless of the distribution of x. (R type 8)
• (3/8,3/8): \( p(k) = \frac{(k-3/8)}{n+1/4} \), Blom. The resulting quantile estimates are approximately unbiased if x is normally distributed (R type 9)
• (0.4,.4): approximately quantile unbiased (Cunnane)
• (.35,.35): APL, used with PWM
• (.3175,.3175): used in scipy.stats.probplot

Parameters

data : array_like
  Input data, as a sequence or array of dimension at most 2.
alpha : float, optional
  Plotting positions parameter. Default is 0.4.
beta : float, optional
  Plotting positions parameter. Default is 0.4.

Returns

data : array_like
  The calculated plotting positions.

scipy.stats.mstats.mjci(data, prob=[0.25, 0.5, 0.75], axis=None)
  Returns the Maritz-Jarrett estimators of the standard error of selected experimental quantiles of the data.

Parameters

data : ndarray
  Data array.
prob : sequence, optional
  Sequence of quantiles to compute.
axis : int or None, optional
  Axis along which to compute the quantiles. If None, use a flattened array.

scipy.stats.mstats.mquantiles_cimj(data, prob=[0.25, 0.5, 0.75], alpha=0.05, axis=None)
  Computes the alpha confidence interval for the selected quantiles of the data, with Maritz-Jarrett estimators.

Parameters

data : ndarray
  Data array.
prob : sequence, optional
  Sequence of quantiles to compute.
alpha : float, optional
  Confidence level of the intervals.
axis : int or None, optional
  Axis along which to compute the quantiles. If None, use a flattened array.

Returns

ci_lower : ndarray
  The lower boundaries of the confidence interval. Of the same length as prob.
ci_upper : ndarray
  The upper boundaries of the confidence interval. Of the same length as prob.
scipy.stats.mstats.rsh(data, points=None)
Evaluates Rosenblatt’s shifted histogram estimators for each data point.
Rosenblatt’s estimator is a centered finite-difference approximation to the derivative of the empirical cumulative distribution function.

Parameters
- **data**: sequence
  Input data, should be 1-D. Masked values are ignored.
- **points**: sequence or None, optional
  Sequence of points where to evaluate Rosenblatt shifted histogram. If None, use the data.

scipy.stats.mstats.sen_seasonal_slopes(x)

scipy.stats.mstats.trimmed_mean(a, limits=(0.1, 0.1), inclusive=(1, 1), relative=True, axis=None)

scipy.stats.mstats.trimmed_mean_ci(data, limits=(0.2, 0.2), inclusive=(True, True), alpha=0.05, axis=None)
Selected confidence interval of the trimmed mean along the given axis.

Parameters
- **data**: array_like
  Input data.
- **limits**: {None, tuple}, optional
  None or a two item tuple. Tuple of the percentages to cut on each side of the array, with respect to the number of unmasked data, as floats between 0. and 1. If n is the number of unmasked data before trimming, then (n * limits[0])th smallest data and (n * limits[1])th largest data are masked. The total number of unmasked data after trimming is n * (1. - sum(limits)). The value of one limit can be set to None to indicate an open interval.
  Defaults to (0.2, 0.2).
- **inclusive**: (2,) tuple of boolean, optional
  If relative==False, tuple indicating whether values exactly equal to the absolute limits are allowed. If relative==True, tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False).
  Defaults to (True, True).
- **alpha**: float, optional
  Confidence level of the intervals.
  Defaults to 0.05.
- **axis**: int, optional
  Axis along which to cut. If None, uses a flattened version of data.

Returns
- **trimmed_mean_ci**: (2,) ndarray
  The lower and upper confidence intervals of the trimmed data.

scipy.stats.mstats.trimmed_std(a, limits=(0.1, 0.1), inclusive=(1, 1), relative=True, axis=None, ddof=0)

scipy.stats.mstats.trimmed_var(a, limits=(0.1, 0.1), inclusive=(1, 1), relative=True, axis=None, ddof=0)

scipy.stats.mstats.ttest_1samp(a, popmean, axis=0)
Calculates the T-test for the mean of ONE group of scores.

Parameters
- **a**: array_like
  sample observation
**popmean**: float or array_like

Expected value in null hypothesis, if array_like than it must have the same shape as `a` excluding the axis dimension

**axis**: int or None, optional

Axis along which to compute test. If None, compute over the whole array

**Returns**

**statistic**: float or array
t-statistic

**pvalue**: float or array
two-tailed p-value

**Notes**

For more details on `ttest_1samp`, see `stats.ttest_1samp`.

### 5.27.9 Univariate and multivariate kernel density estimation (**scipy.stats.kde**) 2075

**gaussian_kde**(dataset[, bw_method])

Representation of a kernel-density estimate using Gaussian kernels.

**class** *scipy.stats.gaussian_kde*(dataset, bw_method=None)

Representation of a kernel-density estimate using Gaussian kernels.

Kernel density estimation is a way to estimate the probability density function (PDF) of a random variable in a non-parametric way. `gaussian_kde` works for both uni-variate and multi-variate data. It includes automatic bandwidth determination. The estimation works best for a unimodal distribution; bimodal or multi-modal distributions tend to be oversmoothed.

**Parameters**

**dataset**: array_like

Datapoints to estimate from. In case of univariate data this is a 1-D array, otherwise a 2-D array with shape (# of dims, # of data).

**bw_method**: str, scalar or callable, optional

The method used to calculate the estimator bandwidth. This can be ‘scott’, ‘silverman’, a scalar constant or a callable. If a scalar, this will be used directly as `kde.factor`. If a callable, it should take a `gaussian_kde` instance as only parameter and return a scalar. If None (default), ‘scott’ is used. See Notes for more details.

**Notes**

Bandwidth selection strongly influences the estimate obtained from the KDE (much more so than the actual shape of the kernel). Bandwidth selection can be done by a “rule of thumb”, by cross-validation, by “plug-in methods” or by other means; see [R644], [R645] for reviews. `gaussian_kde` uses a rule of thumb, the default is Scott’s Rule.

Scott’s Rule [R642], implemented as `scotts_factor`, is:

\[ n^{-1/(d+4)}, \]

with \( n \) the number of data points and \( d \) the number of dimensions. Silverman’s Rule [R643], implemented as `silverman_factor`, is:

\[ (n \cdot (d + 2) / 4.)^{-1/(d+4)}. \]

Good general descriptions of kernel density estimation can be found in [R642] and [R643], the mathematics for this multi-dimensional implementation can be found in [R642].
Examples

Generate some random two-dimensional data:

```python
>>> from scipy import stats
>>> def measure(n):
...     "Measurement model, return two coupled measurements."
...     m1 = np.random.normal(size=n)
...     m2 = np.random.normal(scale=0.5, size=n)
...     return m1+m2, m1-m2

>>> m1, m2 = measure(2000)
>>> xmin = m1.min()
>>> xmax = m1.max()
>>> ymin = m2.min()
>>> ymax = m2.max()
```

Perform a kernel density estimate on the data:

```python
>>> X, Y = np.mgrid[xmin:xmax:100j, ymin:ymax:100j]
>>> positions = np.vstack([X.ravel(), Y.ravel()])
>>> values = np.vstack([m1, m2])
>>> kernel = stats.gaussian_kde(values)
>>> Z = np.reshape(kernel(positions).T, X.shape)
```

Plot the results:

```python
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots()
>>> ax.imshow(np.rot90(Z), cmap=plt.cm.gist_earth_r,
...     extent=[xmin, xmax, ymin, ymax])
>>> ax.plot(m1, m2, 'k.', markersize=2)
>>> ax.set_xlim([xmin, xmax])
>>> ax.set_ylim([ymin, ymax])
>>> plt.show()
```

</table>

### Example

```python
gaussian_kde.evaluate(points)
```
Evaluate the estimated pdf on a set of points.
**Parameters**

points : (# of dimensions, # of points)-array
    Alternatively, a (# of dimensions,) vector can be passed in and treated
    as a single point.

**Returns**

values : (# of points,)-array
    The values at each point.

**Raises**

ValueError : if the dimensionality of the input points is different than
    the dimensionality of the KDE.

**gaussian_kde.\_\_call\_\_**

Evaluate the estimated pdf on a set of points.

**Parameters**

points : (# of dimensions, # of points)-array
    Alternatively, a (# of dimensions,) vector can be passed in and treated
    as a single point.

**Returns**

values : (# of points,)-array
    The values at each point.

**Raises**

ValueError : if the dimensionality of the input points is different than
    the dimensionality of the KDE.

**gaussian_kde.integrate_gaussian**

Multiply estimated density by a multivariate Gaussian and integrate over the whole space.

**Parameters**

mean : array_like
    A 1-D array, specifying the mean of the Gaussian.

cov : array_like
    A 2-D array, specifying the covariance matrix of the Gaussian.

**Returns**

result : scalar
    The value of the integral.

**Raises**

ValueError
    If the mean or covariance of the input Gaussian differs from the
    KDE's dimensionality.

**gaussian_kde.integrate_box_1d**

Computes the integral of a 1D pdf between two bounds.

**Parameters**

low : scalar
    Lower bound of integration.

high : scalar
    Upper bound of integration.

**Returns**

value : scalar
    The result of the integral.

**Raises**

ValueError
    If the KDE is over more than one dimension.

**gaussian_kde.integrate_box**

Computes the integral of a pdf over a rectangular interval.

**Parameters**

low_bounds : array_like
    A 1-D array containing the lower bounds of integration.

high_bounds : array_like
    A 1-D array containing the upper bounds of integration.

maxpts : int, optional
    The maximum number of points to use for integration.

**Returns**

value : scalar
    The maximum number of points to use for integration.

**Raises**

ValueError
    The result of the integral.

**gaussian_kde.integrate_kde**

Computes the integral of the product of this kernel density estimate with another.

**Parameters**

other : gaussian_kde instance
    The other kde.

**Returns**

value : scalar
    The result of the integral.

**Raises**

ValueError
If the KDEs have different dimensionality.

**gaussian_kde.pdf**

Evaluate the estimated pdf on a provided set of points.

**Notes**

This is an alias for `gaussian_kde.evaluate`. See the `evaluate` docstring for more details.

**gaussian_kde.logpdf**

Evaluate the log of the estimated pdf on a provided set of points.

**gaussian_kde.resample**

Randomly sample a dataset from the estimated pdf.

- **Parameters**
  
  size : int, optional

  The number of samples to draw. If not provided, then the size is the same as the underlying dataset.

- **Returns**

  resample : (self.d, size) ndarray

  The sampled dataset.

**gaussian_kde.set_bandwidth**

Compute the estimator bandwidth with given method.

The new bandwidth calculated after a call to `set_bandwidth` is used for subsequent evaluations of the estimated density.

- **Parameters**

  bw_method : str, scalar or callable, optional

  The method used to calculate the estimator bandwidth. This can be 'scott', 'silverman', a scalar constant or a callable. If a scalar, this will be used directly as `kde.factor`. If a callable, it should take a `gaussian_kde` instance as only parameter and return a scalar. If None (default), nothing happens; the current `kde.covariance_factor` method is kept.

**Notes**

New in version 0.11.

**Examples**

```python
>>> import scipy.stats as stats
>>> x1 = np.array([-7, -5, 1, 4, 5.])
>>> kde = stats.gaussian_kde(x1)
>>> xs = np.linspace(-10, 10, num=50)
>>> y1 = kde(xs)
>>> kde.set_bandwidth(bw_method='silverman')
>>> y2 = kde(xs)
>>> kde.set_bandwidth(bw_method=kde.factor / 3.)
>>> y3 = kde(xs)
```

```python
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots()
>>> ax.plot(x1, np.ones(x1.shape) / (4. * x1.size), 'bo',
...         label='Data points (rescaled)')
>>> ax.plot(xs, y1, label='Scott (default)')
>>> ax.plot(xs, y2, label='Silverman')
>>> ax.plot(xs, y3, label='Const (1/3 * Silverman)')
>>> ax.legend()
>>> plt.show()
```
gaussian_kde.covariance_factor()  
Computes the coefficient (kde.factor) that multiplies the data covariance matrix to obtain the kernel covariance matrix. The default is scotts_factor. A subclass can overwrite this method to provide a different method, or set it through a call to kde.set_bandwidth.

For many more stat related functions install the software R and the interface package rpy.

### 5.28 Low-level callback functions

Some functions in SciPy take as arguments callback functions, which can either be python callables or low-level compiled functions. Using compiled callback functions can improve performance somewhat by avoiding wrapping data in Python objects.

Such low-level functions in Scipy are wrapped in LowLevelCallable objects, which can be constructed from function pointers obtained from ctypes, cffi, Cython, or contained in Python PyCapsule objects.

**class scipy.LowLevelCallable**  
Low-level callback function.

**Parameters**  
function : {PyCapsule, ctypes function pointer, cffi function pointer}  
Low-level callback function.

user_data : {PyCapsule, ctypes void pointer, cffi void pointer}  
User data to pass on to the callback function.

signature : str, optional  
Signature of the function. If omitted, determined from function, if possible.

**Notes**

The argument function can be one of:

- PyCapsule, whose name contains the C function signature
- ctypes function pointer
- cffi function pointer
The signature of the low-level callback must match one of those expected by the routine it is passed to.
If constructing low-level functions from a PyCapsule, the name of the capsule must be the corresponding signature, in the format:

```
return_type (arg1_type, arg2_type, ...)
```

For example:

```
"void (double)"
"double (double, int *, void *)"
```

The context of a PyCapsule passed in as `function` is used as `user_data`, if an explicit value for `user_data` was not given.

**Attributes**

<table>
<thead>
<tr>
<th>function</th>
<th>Callback function given</th>
</tr>
</thead>
<tbody>
<tr>
<td>user_data</td>
<td>User data given</td>
</tr>
<tr>
<td>signature</td>
<td>Signature of the function.</td>
</tr>
</tbody>
</table>

**Methods**

```
from_cython(module, name[, user_data, signature])
```

Create a low-level callback function from an exported Cython function.

**classmethod** `LowLevelCallable.from_cython(module, name, user_data=None, signature=None)`

Create a low-level callback function from an exported Cython function.

**Parameters**

- `module`: module
  Cython module where the exported function resides
- `name`: str
  Name of the exported function
- `user_data`: {PyCapsule, ctypes void pointer, cffi void pointer}, optional
  User data to pass on to the callback function.
- `signature`: str, optional
  Signature of the function. If omitted, determined from `function`.

**See also:**

Functions accepting low-level callables:

- `scipy.integrate.quad`
- `scipy.ndimage.generic_filter`
- `scipy.ndimage.generic_filter1d`
- `scipy.ndimage.geometric_transform`
